The Prevention of Syphilis.—The microorganism of syphilis, *Spriochæta pallida*, is strictly parasitic. On being discharged from the body it soon perishes and becomes innocuous, so that infection through the medium of table dishes, public drinking cups, barbers' razors, etc., can be contracted only by contact with the utensil immediately following its use by a syphilitic person. Lower animals do not have syphilis, though in recent years monkeys have been successfully inoculated experimentally. Therefore from the bacteriological standpoint syphilis should be more readily preventable than any other common infectious disease. The problem of its prevention is, however, complicated by certain sociological features which still await solution and which render this disease so prevalent a plague of mankind.

Syphilitic infection, as is well known, may be of non-venereal as well as of venereal origin. Thus of 887 cases reported by Fournier 45 were of non-venereal origin, among them being cases of inherited syphilis, of infection of wet-nurses by sucklings, midwives by women in labor, etc. Of the cases of venereal origin not all result from immoral relations. Thus Fournier[20] estimates that of all cases in women the infection is in 19 per cent. acquired by married women from their husbands. But even in cases in which the infection is acquired innocently it can usually be traced indirectly to immoral sexual relations, particularly to prostitution, as its original source.

The prevention of syphilis is therefore closely linked to the prevention or control of prostitution.

Prostitution cannot be studied as an independent phenomenon; on the contrary, like the commerce of any commodity, it seems to vary and fluctuate in accordance with the general principles of demand and supply. Thus we find it flourishing in large industrial centers and in seaport towns, but rare in residential towns and almost unknown in farming communities. We can follow its rise and decline in response to rise and decline of the demand in towns in which armies in the course of their maneuvers arrive to be stationed for a time and then proceed elsewhere. Where the demand is steady prostitution becomes organized, brothels are established, proxenetism appears. It may be further noted that the demand is greater for some classes of men—as soldiers, sailors, traveling salesmen, railroad employees—than for others. Thus, for instance, in the United States Navy and Marine Corps out of 697.29 admissions to the sick list per thousand of average strength of the services, 199.17 were for venereal disease, and the remaining 498.12 were for all other diseases and injuries.[21] When it is considered that in most cases venereal disease does not necessitate admission to the sick-list and that, therefore, these figures represent but a fraction of the total amount of venereal disease some idea of the real incidence of such disease in the navy and marine corps can be formed.

Why should prostitution be so much more prevalent in some communities than in others? Why should certain classes of men suffer so much more than others from venereal disease? It seems to me that a mere presentation of the facts reveals the cause, and it may be assumed as a general principle that any factor which interferes with the institution of marriage and the organization and maintenance of homes will bring about aberration of the sexual instinct leading to immoral relations, promiscuous relations, prostitution, venereal disease, and ultimately to certain forms of nervous disease and insanity.

It is easy to see how modern civilization by increasing the cost and at the same time raising the standard of living; by the inadequate compensation of labor; by the maintenance of armies and navies; and by some smaller factors such as the preference given by governments, municipalities, and industrial organizations to unmarried employees over married ones, accounts in part for the increase of insanity, and we can now fully grasp the significance of Krafft-Ebing's celebrated epigram: "General paresis is a disease of civilization and syphilization."

To what extent can prostitution be controlled? First of all it must be noted that at no time has any state or nation succeeded in abolishing prostitution, and in 1902 a Committee of Fifteen organized in New York for the purpose of investigating the social evil was led in its report to express the view

that the summary extirpation of prostitution "in the present state of the moral evolution of the race is as yet impossible."[22]

In some municipalities prostitution is by the law classed as a crime and is punishable as such. In others it is licensed and regulated with a view to providing sanitary inspection. Neither system has effected either actual control of prostitution or any material reduction of the incidence of venereal disease. The Committee of Fifteen in the above quoted report suggests the following as the proper attitude for the law: "Not prostitution itself, when withdrawn from the public eye so as to be noticeable only to those who go in search of it, shall be punishable; but all such manifestations of it as belong under the heading of public nuisance." In accordance with this principle the law may punish street soliciting, proxenetism, the establishment of brothels in tenement or apartment houses, etc.

There remains one thing, namely, the prevention of syphilis without reference to prostitution by measures which have been so successful in the prevention of other communicable diseases; that is to say, the compulsory reporting of all cases of syphilis, regardless of the manner or source of infection, and their hospitalization, if necessary, during the periods of greatest infectiousness.

Owing to the fact that during the primary and secondary stages—the periods of greatest infectiousness—syphilis does not generally incapacitate the patient, treatment in a hospital is not sought and facilities for it not provided. Thus the Committee of Fifteen reports "that the great city of New York provides for the reception of women suffering from venereal diseases only twenty-six beds in the City Hospital on Blackwell's Island." Another difficulty lies in the fact that the period of infectiousness is often very long—three years or longer.

The recent discovery by Ehrlich and Hata of a remedy which is apparently much more efficacious than mercury or iodides, namely, dioxydiamidoarsenobenzol, also known as "606" or "salvarsan," bids fair to become a more potent means of preventing the spread of syphilis than any that we have heretofore possessed. Although it is as yet too early to say whether this substance completely and permanently cures syphilis or whether it affects in any way the prospect of the development of parasyphilitic or postsyphilitic conditions, extensive experience has already shown that in almost all cases it causes the disappearance of the *Spirochæta pallida* from all superficial lesions which is followed by a prompt healing of the lesions themselves.[23] In about half of the cases the Wassermann reaction becomes negative after a period varying from one to ten weeks following one or two injections.[24] Thus there is ground for hope that the infectious period of syphilis will be reduced by means of this remedy from several years to but as many weeks, thus rendering the hospitalization of cases of syphilis entirely practicable.

Two other measures of prophylaxis against syphilis deserve special mention: measures that may be employed within twelve or eighteen hours following exposure to infection, and measures for the prevention of hereditary syphilis.

It has been shown by Metchnikoff and Roux[25] that in monkeys local inunction with calomel ointment applied within one hour following experimental inoculation prevents infection in all cases, while control animals invariably develop a chancre at the expiration of the usual period of incubation. Later a pupil of Metchnikoff submitted to experimental inoculation, followed in an hour by prophylactic inunction, and failed to become infected; at the same time four monkeys were inoculated with the same virus; one received the prophylactic inunction after an hour and failed to become infected; another received the inunction at the end of twenty hours; this one as well as the remaining two, which did not receive the inunction, became infected.

Numerous opportunities of testing this prohylactic treatment have since occurred and the results seem to prove it to be of almost unfailing efficacy according to the reports of some medical officers of the United States Navy. Thus Diehl, Fleet-Surgeon of the United States Asiatic Fleet, submits the following statistics in his report for the year 1909:[26]

Number of men who upon return from liberty failed to report and received no treatment	5,319
Number who developed venereal disease	113 (2.12%)
Number who upon return from liberty admitted exposure and received treatment	21,166
Number of those who developed venereal disease attributed to delay of treatment on account of overstaying of liberty or extended liberty	225
Number who developed venereal disease attributed to failure of prophylactic treatment	176 (0.83%)

It is pointed out, however, that "in some instances supervision of treatment lacked thoroughness" and that, "with a greater familiarity with and more thorough application of the scheme, the failures, pure and simple, will be greatly reduced." This opinion seems to be fully borne out by the reports from the United States steamships *Galveston, Ranger,* and *Tacoma* of 281, 256, and 756 exposures, respectively, in various notoriously infected ports, followed by prompt and thorough prophylactic treatment without the development of venereal infection in any case but two of gonorrhea in men who overstayed liberty.[27]

As to the prevention of hereditary syphilis, syphilitics must be advised not to marry until they have had three years of methodical treatment, or, if the treatment has been neglected or irregular, until five years have elapsed from the onset of the disease: and then only if no contraindication is found upon examination. It is needless to add that in most cases no attention is paid to such advice. Yet it is remarkable that a radical change often occurs in a syphilitic, with regard to his attitude toward his disease, after marriage. Thus Fournier states: "We are consulted by a syphilitic who is about to become a father, and who asks us whether something cannot be done to prevent his child from inheriting the disease. This is not an uncommon situation—indeed, from my personal experience, I should say that even if the syphilitic takes but little care of his disease before marriage, he is very apprehensive of it as soon as he is about to become a father. This is a curious phenomenon in psychology which I have observed hundreds of times."

For the prevention of hereditary syphilis in such cases Fournier gives the following rule: "When a woman is pregnant with a child threatened, by paternal antecedents, with syphilitic heredity, syphilitic treatment of the mother, although healthy, constitutes for this child a real and powerful safeguard for which there is a precise and formal indication."[28]

The Prevention of Head Injuries.—There is but little to be said with reference to head injuries,

which, like other injuries resulting in either disability or death, have become common as a result of the great modern development of industries, means of transportation, etc. It may be pointed out, however, that in the United States, owing probably to imperfect legislative protection, serious accidents are needlessly frequent, as may be judged from the example furnished by American and British railroad statistics. These, for the year 1906, are given in the following table:[29]

	American Railroads.	British Railroads.
Total number of passengers carried	800,000,000	1,200,000,000
Total miles of track	200,000	27,000
Number of collisions and derailments	13 455	239
Number of passengers killed	146	58
Number of passengers injured	6,000	631
Number of employees killed	879	13
Number of employees injured	7 483	140

The Individual.—From what has already been said it follows that an individual who comes from normal stock, abstains from alcohol, is free from syphilis, and escapes accidental head injury is not threatened with mental alienation.

It is not so with the neuropathic individual: for him every feature of life in society presents possible dangers. From childhood up the adjustment between him and his environment must be nicely controlled if the danger of a mental breakdown is to be minimized; his bringing-up at home, his education at school, his sexual life, his career, his social and family relations are great matters for special adjustment, particularly with the ends in view of proper habit training, avoidance of the incidental causes referred to in the beginning of this paper as possessing quasi-specific potency in the production of mental alienation, and prompt institution of treatment upon the appearance of any symptoms.

It is obvious that the recognition of the neuropathic make-up is of the highest importance. In cases of pronounced feeblemindedness, frank insanity, epilepsy, or well marked hysteria no difficulty is experienced, the condition being apparent even to a lay person. In other cases in which a lay observer may notice mental dullness, or eccentricity, or criminal tendency a systematic inquiry by an experienced alienist may reveal evidence of one of the special types of abnormal make-up which is the characteristic soil upon which dementia precox, manic-depressive insanity, or involution melancholia develops.[30] The application of the Binet-Simon tests[31] may aid in the detection of high grades of imbecility, and the association test has in some cases revealed evidences of mental abnormality not otherwise observed: "Mental disorders do not always so manifest themselves as to incapacitate the subject for his work or to necessitate his sequestration in a hospital for the insane. It is therefore not surprising that in applying the association test to over a thousand subjects selected at random we have obtained a small number of test records which show various types of abnormal reactions. Among the subjects who furnished such records some are described as eccentric, taciturn, or dull, while others are apparently normal but come of neuropathic stock."[32] Finally, in still other cases the neuropathic make-up or taint may exhibit no symptoms and may be only surmised to exist on the basis of a neuropathic family history.

THE ETIOLOGY OF PANCREATIC DISEASES.*

By JAMES E. DAVIS, M.D.,

DETROIT, MICH.,

LECTURER IN PHYSIOLOGY DETROIT COLLEGE OF MEDICINE AND GASTRO-ENTEROLOGIST TO PROVIDENCE HOSPITAL, DETROIT.

"Medicine is nothing more than the physiology of the sick man."—Magendie.

It is a biological law of far-reaching significance that *function determines the form of tissue structure*. The involved form of structure secures the greatest possible economy of kinetic expenditure by (1) means of direct or indirect canalization, by (2) community (or analogous) cell assembling, and by (3) provisional evolutionary adjustment of embryonic and complex types of tissue structure for a common function. Illustrative of facilitated function by both direct and indirect canalization is the course of the pancreatic secretion in Wirsung's duct. The route to the duodenum by the duct of Santorini is more direct, yet, by the indirect canal, utility of function is better accomplished, for the exit is in common with the bile duct into the ampulla of Vater, which serves as a convenient mixing chamber. The synergistic value of the bile and intestinal secretions is here immediately obtained. The advantage, then, for functional purposes in the utilization of Wirsung's canal is plainly evident, as is also the disadvantage herein involved by intimate association of a relatively immune structure with a frequently involved one, as the bile duct.

The assembling of cells of intimate and remote functional importance for the performance of complex functions is well shown in the alimentary canal, for with its adnexia and innervation it contains elements from the three blastodermic layers.

(1) In the early embryonic formation of the body systems, when function is not yet demanded, one has a perfect right to designate the intestinal glands as organs of the hypoblastic germ layer; the muscles, the sexual and urinary organs as belonging to the mesoblastic, and the nervous system, together with the sensory organs to the ectodermic germ layers. It is because the various tissues are of unequal value in the construction and function of an organ that selection is made chiefly from a single germ layer and according to its organic function from all layers. The close topographical arrangement of the liver and pancreas—the chief appendages of the alimentary canal—together with the stomach, is functionally advantageous; but, considered in relation to disease etiology it would seem a disadvantage. The pancreas is a tubulo-racemose gland possessing remarkable functioning powers. Its canalization is elaborate. Its cells are varied from the[1] apparently primitive type in the areas of Langerhans to the[2] columnar or polyhedral shaped cells lining the alveoli, which are richly supplied with convoluted ducts. These ducts are associated so as to make a lobule, and drain promptly into the duodenum the so-called external secretion. Development of the pancreas is completed in all vertebrates, with the exception of a few types of bony fishes in which it appears to be wanting—and proceeds from the gut hypoblast derived from the second part of the duodenum. Its appearance in man is shortly after the primitive hepatic tube. His[3] was able to demonstrate the small evagination in embryos 8 mm. long. The growth proceeds from at least two buds, one from the dorsal intestinal wall, from which is developed the duct of Santorini, and the larger part of the gland, and the other from the common duct. The two pancreatic parts or ducts coalesce a little distance to the left of the duodenum, forming what is defined as the head. The triangle here formed by the duodenum as a base and the ducts as sides is regarded clinically as the specific danger area or *triangle of infection* in the pancreas. After the formation of the head the neck and body grow upward into the dorsal mesentery until rotation of the stomach is complete; then the organ, if fully grown, appears horizontal, and the tail is in immediate proximity with the spleen. The position is now behind the stomach and the lesser sac of the peritoneum.[4] It lies in front of the aorta, in the fork between the celiac axis above and the superior mesenteric artery below. The portal vein passes upward behind the neck of the gland. The close proximity of the organ to other important structures, especially the solar plexus, is surgically very important. With normal conditions existing the pancreas could scarcely have a position within the abdomen of securer shelter; yet withal it is subject not infrequently to secondary involvement, and more frequently perhaps to primary disease than our present knowledge implies.

Mayo[5] says the natural defences of the great abdominal gland have a single defect, *i.e.* the mechanical association of the main pancreatic duct with the common duct. The duct of Santorini empties into the anterior part of the duodenum, about three-quarters to one inch above the exit of Wirsung's duct, and according to Mayo is capable of maintaining pancreatic secretion in 50 per cent. of cases examined. The same author says that neither of the pancreatic ducts has valves, but the ampulla of Vater is so provided. It would seem as this valve is found only in carnivora, that it is a structural form evolved to protect the ducts Wirsung and communis choledochus from intestinal infection. Helly[5] has found that the terminal one-third of the common duct is embedded by pancreatic tissue in 62 per cent. of subjects, and in the remaining 38 per cent. it lies behind the pancreas, making a groove between this organ and the duodenum. By this topography it is easy to explain the etiology of most pancreatic diseases occurring in the proximal end of the gland. The occurrence of hypertrophic or atrophic changes in the head of the pancreas must promptly make partial or complete closure of the common duct imminent, and resulting jaundice, and likewise occlusion of the common duct by stone or other cause at once tends to infection of the duct of Wirsung, and eventually the gland proper. In the event of a stone lodging in the papilla the bile may be forced up the duct of Wirsung and drainage through the duct of Santorini, if possible, may determine the safety of the gland against infection. According to Opie[5] the large percentage of this class of pancreatic diseases owe their etiology to the foregoing association of terminal facilities.

In leaving the foregoing phase of the subject it should be said that as an extensive literature is easily available to one interested in the further development of the surgery of the pancreas, attention will now be directed to the field of pancreatic study presenting problems of much greater intricacy. The physiology and histology of the pancreas will be reviewed only as added clearness can be given to

*Read before the Detroit Medical Club and the Wayne County Medical Society.

the ensuing discussion. According to the knowledge before us, the pancreas has four enzymes or their precursors, that leave the gland by way of the excretory duct, viz., amylopsin, which can be extracted from the fresh gland, and is capable of hydrolyzing over 40,000 times its weight of starch; trypsinogen, the precursor of trypsin, is the most powerful proteid digestant known, the activating enzyme of which is enterokinase of the succus entericus; steapsin, which is probably activated by bile and is capable of splitting up entire fats, as shown by Ratchford[6], and the milk-curdling ferment of Kuhne. In addition to the foregoing Bayliss and Starling discovered a hormone secretion, which is destroyed by boiling in acid solution, and is therefore not an enzyme, obtained from the mucous membrane of the duodenum or upper end of the jejunum, which evokes a copious flow of pancreatic juice if intravenously injected. Also, Cohnheim found a body in the pancreas which he calls the activator, which resembles an internal secretion like adrenalin. When this activator is added to muscle extract it breaks up the sugar in the blood. Seventy-five grains of muscle and about .08 grain of pancreas represent proportions that destroy the greatest amount of glucose.

The secreting cells of the pancreas, when fully charged with their granular substance, are never quite full. The alveoli or sac, however, holding these charged cells appears loaded so compactly as to make the lumen indistinct. After active secretion the cells shrink and the lumen is apparent. The lumen of the alveoli, when injected by the Golgi method of staining with silver chromate, show penetration by the intracellular canals. These canals or ducts to the individual alveoli are the narrow distal or ultimate branches which become interlobular, and eventually empty into the main duct for the purpose of carrying to the intestine for complete activation the secretion given up by the zymogen granules of the alveoli. The secretion of pancreatic juice is greatest about two hours after ingestion of food, and during the fasting period it almost ceases. During fasting the zymogen granules disappear, and only the underlying basement protoplasm from which the cells have been formed can be seen.

The symptom complex in diseases of the pancreas, liver, stomach, bile ducts, and duodenum is so frequently impossible to differentiate that correlated physiological and etiological factors must be passed in review. The blood supply of the pancreas, excepting the areas of Langerhans, is clearly defined in the textbooks. The lymph circulation has not been described in the literature examined excepting a brief mention that the spleen and pancreas empty their lymph stream into a common vessel which passes a common node supply, then empties after a short course into the receptaculum chyli. The nerve supply is, according to most recent writers, from the vagi and sympathetic. The secretory fibers, like those of the stomach, are from the vagus, and they are probably connected with a reflex center in the medulla.[7] Huber[8] quotes Cajal and Sala and Erik Müller as finding large numbers of nonmedullated nerve fibers, some coming from sympathetic ganglion cells in the pancreas and others entering from without. It is quite probable that excitatory and inhibitory stimuli are supplied by the vagus and splanchnic nerves.

The etiology of pancreatic diseases is most profitably studied by proceeding under two classifications; first, diseases involving a pathology of the gland, exclusive of the islands of Langerhans; second, diseases of the islands with secondary involvement only of the pancreas proper. The etiology of the first class is arranged by Adami[9] as follows: Circulatory disturbances caused by trauma and the anemias. Inflammations are caused by microorganisms, infecting through the blood stream, excretory duct, and by extension. The common entrance is by Wirsung's duct, and the source of infection is usually intestinal bacteria, bile and acid stomach secretions. Alcoholism is assigned by Adami as the most common cause of the hemorragic and fat necrosis forms. Tuberculosis and syphilis of the pancreas are rare.

Retrogressive changes occur in old age and in the marasmus of infective or chronic diseases. The organ is small, shrunken and cylindrical on section. DeWitt[10], however, has found very little change in the islands of Langerhans from senility. Fat necrosis, a retrogressive change, is frequently seen in the obese and where intraabdominal circulation is hindered. Hildebrand and Flexner have shown that fat necrosis is due to a liberation of the fat-splitting ferment, which acts upon any adjacent fatty tissue. Progressive changes of the pancreas are rare, for Segil[11], in 11,500 autopsies at Milan, found but 132 cases. It was as late as 1869 that Langerhans gave the first description of the islands of the pancreas which now bear his name. During the last few years a vast amount of patient research work has been given to these areas. These islands are found distributed throughout the pancreas, but are doubtless independent organs with an independent function. An average of one island is found in each square mm. of the pancreas. Opie says they are four times as numerous in the tail as in any other part. Laguesse estimates that $^1/_{100}$ part of the entire gland is area of Langerhans. These areas are quite similar in structure in all vertebrates, consisting of masses of epithelial cells derived from the same bud, as the pancreatic acini. The cells are packed in single rows, separated by blood vessels with complete endothelial walls and no, or very little, adventitia. The vascular network is made up of windings, branchings and anastomoses of several larger vessels of venous origin and large numbers of capillaries, which communicate intimately with the interacinar capillary plexus.[12] In a recent paper published in the *Internationale Monatschrift für Anatomie and Physiologie*, Vincent and Thompson, of the University of Manitoba, report elaborate work done by them on the relations between the islets of Langerhans and the zymogenous tubules of the pancreas. Their observations were made upon pancreatic tissues of mammals, birds, reptiles, amphibians and fishes. They make the conclusions that in the vertebrate pancreas there are two kinds of tissues in addition to the ordinary zymogenous tubules—the leptochrome tissue forming the islets and the bathychrome tissue represented in mammals for the most part as small groups of cells, or even solitary elements scattered throughout the secreting alveoli. The islet columns were found by these authors frequently in complete anatomical continuity with the surrounding zymogenous tubules; and all kinds of transition forms are common throughout vertebrates. The effects of exhaustion and inanition upon the mammalian pancreas is to markedly increase the amount of leptochrome islet tissue at the expense of zymogenous tissue. In this condition

direct continuity and branching forms were even more marked than in the normal animal. They presume that alveoli, after inanition, are reconstructed from islets, and they take the position, with Dale, Harris and Gow,[13] that the islands of Langerhans may have an internal secretion, but the evidence is not considered conclusive. Jasotzky[14] believes the islands possess both an internal and external secretion. Warthin[15] says he has undoubtedly seen islands of Langerhans developing at the acini, but his position regarding an internal secretion is unstated. Among the authors who have done notable work upon this subject, and who undoubtedly conclude in favor of the islands of Langerhans may be mentioned Diamare, Rennie, Massari, Helly, Ssobolow, Opie, Pensa, and DeWitt.[16] The last named author writing in the *Journal of Experimental Medicine*, draws the following conclusions: "There occur in the pancreas of all vertebrates homologous structures, known as areas of Langerhans. These have the structure of vascular glands with a sinusoidal circulation, and are not changed during the secretory activity of the pancreas. They also remain unaltered when the glandular acini become atrophied as a result of ligation, section, or obstruction of the duct. They have a secretion which is probably poured into the blood vessels. This secretion has no digestive action on starch, fibrin, or fat, but has a marked glycolytic function, especially when added to muscle extract, and is therefore analogous to the 'activator principle' described by Cohnheim." It would seem, from the standpoint of a reviewer, that the islands of Langerhans have been shown quite conclusively to have a function independent of the pancreas proper, and that function is contingent upon the production of an internal secretion. In support of this conclusion are the following considerations: The transition forms regarded as probable evidence against their independent structure and function are best explained as resting pancreatic tubules. The protoplasm of these insular cells has been shown by Mankowski to be chemically different, there being a marked difference in affinity for stains. Many experimenters have shown that during extreme atrophy of gland tissue the islands may be well preserved. Rennie[17] has found in all of twenty-five species of osseous fishes very large areas in pancreatic tissue scattered along the abdominal vessels, and among these he finds nearly constantly present a large socalled "principal islet," a short distance in front of the spleen in the mesenteric fold between the portal vein and the mesenteric artery. In *Lophius piscatorius* this principal islet is very large and constant in its position, and is independent of pancreatic tissue.

In considering the etiology of the second class of pancreatic diseases or those involving the function and pathology of the islands of Langerhans, attention will be given almost entirely to diabetes mellitis. The statistics of Sauerbeck[18] record 157 cases of diabetes mellitis, in which 117 showed abnormal islands of Langerhans. In seven cases the islands were not found. In one, scar tissue only remained. The changes described were reduction in size and number, and such qualitative changes as hemorrhage, fatty degeneration, acute and chronic inflammation, simple atrophy, hydropic degeneration, sclerosis, and hyaline degeneration. The foregoing pathology is not conclusive that disease, or even destruction of these islands is causative of diabetes, for many cases have been reported where the entire pancreas has suffered destruction and no diabetes followed, and also many cases of diabetes have shown absolutely no pathology of the pancreas. But weight must be given the consideration that aberrant function, as well as anatomical change, could prove a significant etiologic factor. The known pathology of the brain does not answer etiologically for all of its diseases. Lépine and Thiroloix[19] have shown that glycosuria does not result from pancreas extirpation in dogs if they are starved for some days before operation. Dock[20] has shown that sugar does not appear in the urine after pricking certain nerve cells in the floor of the fourth ventricle (*la piqure* of Bernard) if the animal has been previously starved.

If the internal secretion from these islands is regarder as an activator, it would seem a logical hypothesis to state, in view of the incomplete knowledge upon many of the related histological and pathological problems of the subject, and also in view of the intimate physiological association of the liver, spleen, stomach, and duodenum that compensatory or complementary activation is easily possible. A glycolytic substance has been found, according to many experimenters, in the liver, muscle, blood and other parts of the body. Cohnheim[21] believes that the glycolytic ferment is not active until activated by the pancreas enzyme and he explains the mode of action as similar to Ehrlich's amboceptor and complement. If the blood in the muscle satisfies glycolysis the pancreas is not called upon. Moore, Edie, and Abram[22] have suggested that if the duodenum yields a chemical excitant for the internal secretion of the pancreas, which, if absent, causes diabetes, there are at least three ways in which diabetes may result: (1) The duodenum may fail to yield the secretion; (2) although the secretion is formed, the cells of the pancreas may not be capable of excitation; or (3) although the duodenum and the pancreas are normal, yet there may be changes in the various tissues of the body, such as the liver and the muscles, and as a result of these glycosuria may ensue.

It is a fact becoming a recognized practice by careful clinicians to place much emphasis upon functional tests as the first key to the recognition of pancreatic diseases. Inadequacy or debility of pancreatic function is worthy of at least as much attention as is given to the etiology of gastric diseases in the practice of functional testing. The failure of albumin, fat, and carbohydrate preparation by the pancreas for metabolism should be determined with as much routine as we determine the failure of carbohydrate metabolism. The application of tests for fat, muscle nuclei, ozazones of Cammidge acid intoxications, calcium oxalate crystals, and sugar should become routine measures for determining pancreatic function; whereby the presence or absence of a pancreatic etiology can at least be frequently proven.

During the past year the writer has observed and treated one case of carcinoma and three of diabetes mellitis in which functional tests pointed to involvement of the pancreas. Advantage was frequently taken of the test findings and adjustment made in the quantitative relations of the fat, proteid, and carbohydrate. The results have been positively convincing that very marked relief was consequently afforded; furthermore, in two of the cases which have resulted fatally prolongation of life was very evident.

OCULAR MANIFESTATIONS OF THE PERIPHERAL AFFECTIONS OF THE FIFTH CRANIAL NERVE.*

By GEORGE HUSTON BELL, M.D.,
NEW YORK,
ASSISTANT SURGEON, NEW YORK EYE AND EAR INFIRMARY (OPHTHALMIC DEPARTMENT); MEMBER NEW YORK OPHTHALMOLOGICAL SOCIETY; MEMBER AMERICAN OPHTHALMOLOGICAL SOCIETY AND FELLOW OF THE NEW YORK ACADEMY OF MEDICINE, ETC., ETC.

The trigeminal, or fifth cranial nerve, is chiefly sensory, although it has also an important function in the innervation of the muscles of mastication. It is the purpose of this paper to deal with the peripheral affections of the ophthalmic, the superior and inferior maxillary divisions of the trigeminal, as they are the branches which have close relations with the eye and its appendages. The relations existing between the various branches of this nerve have always been of interest to the ophthalmologist, and why more people do not have acute symptoms from the various nerve terminals when so often so many of them are freely exposed has always been a mystery to me.

Many inflammatory conditions of the eye are due to reflex causes, not the least of which are affections of the teeth. And well may this be so when you stop to consider that the branches of the nerve that supplies the teeth and the eyes come from the same ganglion. Despagnet[1] says we are probably recognizing more and more the real connection between dental and ocular diseases. He holds that the same periosteum which lines the orbital cavity extends to the alveolar border of the upper jaw; the mucous membrane of the mouth is in direct continuation with the conjunctiva. Many times the roots of the upper teeth project directly into the antrum of Highmore and from this situation diseases frequently reach the orbit through the thin partition of bone. The angular artery and certain veins run almost directly from one region to the other. The same general nervous supply reaches both, not only through the fifth cranial but also through the sympathetic. According to Fox[2] "dental affections provoke ocular trouble in two different ways: 1st, by inflammation or irritation of the trigeminal nerve, due to dental affections, causing reflex troubles in a manner similar to that in which neuralgia of the fifth nerve or tic douloureux is produced; 2d, by the extension of the inflammatory process of the dental root toward the maxillary sinus and thence toward the orbit by continuity and contiguity of structure." Fox reports a case in which hypopyon developed in a cataract patient eight days after extraction of lens coincidentally with an abscess of the tooth. The true relation, however, between these structures is not clear. Parinaud[3] has demonstrated that in children of five or six years when they are beginning to lose their deciduous teeth, and also in adults, dental lesions not always apparent may be the starting point of osseous or periosteal changes of the inferior orbital border, of fistula in lachrymal sac or lower lid, and also periostitis of the nasal canal. Henry Power[4] in 1883 read a meritorious paper before the Odontological Society of Great Britain, calling attention to the relationship existing between the teeth and the eyes, and pointing out the occurrence not only of corneal ulcerations but also glaucomatous symptoms, mydriasis, myosis, paralysis of the extraocular muscles, failure of accommodation and exophthalmos in the course of dental diseases. Irritation of the fifth nerve due to carious teeth has produced defects of vision. In this connection Power cites a case which occurred in the practice of Sir William Lawrence, of a man thirty years old who suffered blindness for a period of fifteen months whose vision was restored by the extraction of an upper first molar. An examination of the tooth revealed a small splinter of wood one-fourth of an inch long, undoubtedly the fragment of a toothpick, that had traversed the center of the decayed tooth. Numerous cases of reflex dental origin have been reported from time to time: Cafe, Sloggett,[5] Brucke,[6] Gaine,[7] Allport,[8] Turner,[9] Coleman,[9] Stevens,[10] have recorded instances of amaurosis in which dental disorders have figured as important causative factors. Among other diseases which manifest themselves as a result of inflammation of the trigeminal, whether reflex or inflammatory, may be mentioned: conjunctivitis, neurotic edema, chronic edema of the lids, trophic disorders, glaucoma, phlyctenular conjunctivitis and keratitis, tic douloureux, migraine, neuroparalytic keratitis, ocular pain, photophobia, orbital abscess, iritis, cyclitis, paralysis of accommodation, dilation of the pupil, spasm of the external ocular muscles, orbital cellulitis, and herpes zoster ophthalmicus.

This last-mentioned disease follows the peripheral distribution or the supraorbital nerve. The papules are grouped together along the course of this nerve, accompanied by excruciating neuralgic pains. The cornea frequently becomes involved with disastrous results. The line of demarcation in this disease is well drawn and presents a beautiful clinical picture.

Conjunctivitis has been attributed to disorders of the teeth by Forster, Kempton, Fox, and others

*Read before the New York Institute of Stomatology at the New York Academy of Medicine, October 4, 1910.

in certain cases; this has been relieved by extraction of the offending teeth. According to Brown[11] glaucoma, with its corneal anesthesia, neuralgia and trophic changes in the optic nerve, certainly are attended with involvement of the fifth nerve, but whether the disturbance of the trigeminus is a primary condition has yet to be proved. Nance[12] reports a very interesting case of abscess of the orbit, which resisted the treatment until attention was directed to the teeth. An extraction of a badly decayed tooth (molar) was immediately followed by the escape of a large quantity of pus and antiseptic treatment brought about a rapid amelioration of the orbital and ocular symptoms. De Schweinitz[13] mentions neuralgia of the fifth nerve as one of the exciting causes of glaucoma in eyes predisposed to the disease. Personally I have seen one case of glaucoma in which I thought trifacial neuralgia was one of the exciting causes. Fox also says that dental pains and irritation of the trigeminal nerve cause an increase of the intraocular tension and often produce attacks of acute glaucoma where there is a predisposition to neuralgia.

Wickerkiewicz reports the following observations: "Sometimes after the extraction of a diseased tooth gangrene of the eyelids and orbital abscesses appear; the inflammation attacking the meninges, the patient dies, from meningitis in some cases, proving that thorough antisepsis should be observed even in the extraction of a tooth." Ulceration of the cornea from impaired nutrition may follow undue exposure as in trigeminal palsy; also neuroparalytic keratitis; this is a frequent result of paralysis of the ophthalmic division of the trigeminal and follows frequently after an operation for removal of the Gasserian ganglion. It may also occur in diseases of the trigeminal without anesthesia of the cornea, as pointed out by Jackson.[14] The writer thinks that enough attention is not paid by the ophthalmologist to inflammation of the various branches of the fifth cranial nerve, that a great many headaches, the causes of which remain obscure, even after their errors of refraction have been corrected, and their eyes thoroughly examined, can be traced to the teeth. Often it is necessary to have the patient's blood examined to exclude malaria, anemia, and syphilis. According to Lloyd[15] "migraine or sick headache is a neurosis characterized by pain in the fifth nerve, by affections of vision and by gastric irritation. These three groups of symptoms may be said to constitute the tripod upon which the disease rests."

As far back as 1871 Anstie[16] boldly took the position that migraine is neuralgia of the ophthalmic division of the trigeminus, and that, like the rest of the neuralgias, it is due to degenerative processes going on in the primary nucleus of the nerve. He finds his justification for this classification in the fact that no sharp line can be drawn between the complex form of migraine on which most of the descriptions have been based and to the localized neuralgic form. Even in the life of one individual the disease may change from one to the other of these types. Putnam[17] says that Anstie's designation of migraine as a form of trigeminal neuralgia is too narrow, yet signs and symptoms usually considered as indicating neuralgia are to say the least sometimes mixed with those of migraine. To illustrate this point, the writer will cite a case of migranous neuralgia which came under his observation and treatment.

Mrs. J. T., age 30, consulted me in April, 1907, for sick headache and neuralgia. She has had no children, and no miscarriages. Family history: father and mother both living; health of each splendid. Has two sisters and two brothers, all in good health. Her father and mother as far as she knew had never suffered with headaches. Previous history: has had measles and whooping cough when a child, and influenza four years ago, but has had no sickness of late except these attacks of sick headaches, which came on as near as she could tell about two years previously. They would come on periodically every three or six weeks. These headaches always took the form of a hemicrania and affected the eye of the same side. They generally lasted about three to five days and sometimes, but not always, wound up the attack by nausea and vomiting. After vomiting she would gradually improve. These vomiting spells would come on at the conclusion of the attack, whether she had eaten anything or not for the previous twenty-four hours. Her general health was good and she took lots of exercise and lived out of doors a great deal. She did not use her eyes much for close work and she did not see why she should have so much trouble. Status præsens: I found the right supra- and infra-orbital nerves very sore on pressure. Eyeball also sore to the touch. Ocular conjunctiva somewhat injected and considerable ocular pain. The pupils react well to light and the fundi are normal. Her muscle balance was very good. I found that her error of refraction was a cylinder + 50 at .90 in each eye. I gave her this prescription for a lens to be worn all the time, and also a capsule composed of aspirin, arsenious acid and aconitine to be taken every four hours until she was relieved. Under this treatment she seemed to improve for awhile. The headaches were not so frequent, and the nausea and vomiting were not so pronounced, but the supra- and infra-orbital nerves were still very sore to the touch. I asked her when she had consulted a dentist and she said about two years ago. I made a superficial examination of the teeth and found her gums red, swollen, and spongy. There was pus oozing out around the necks of several of the teeth. She had no toothache and no dental lesions as far as I could see, but she complained of an aching in and around the jaw bone, which she thought came from neuralgia in the eyes. I referred her to her dentist who pronounced the case as one of stomatitis and pyorrhea alveolaris. Under the prophylactic treatment of her teeth and gums she made a splendid recovery. I saw her not long since and she informed me that she wears her glasses now only for reading. This case was a combination of migraine and neuralgia and I would call it migranous neuralgia.

A neuralgic pain of peripheral origin is in all probability due to neuritis. One of the first things I do when a patient comes to me complaining of headaches over the frontal bone and radiating to the temples, is to examine the supra- and infra-orbital branches of the fifth cranial nerve. If on pressure that nerve is sore to the touch, or if the patient winces, I know I am dealing with neuralgia or neuritis of the trigeminal. Of course there are various causes for a neuralgia in this region of the head. Among them may be mentioned errors of refraction, errors of accommodation, errors of muscular balance, catarrhal conditions of the frontal sinus, anemia, malaria, chlorosis, uric acid, rheumatism, excessive cold and heat, syphilis, traumatism, and last but not least, diseases of the teeth and

gums. I always have a superficial look at the teeth when I am dealing with these cases. When you ask your patients when they have seen their dentist last, they say, "Not long since I had him look over my teeth; about six months or one year ago I consulted my dentist, I think." But when you pin them down you will find it has been more like two or three years in a great many cases. The laity should be educated to consult their dentists at least every six months and far better every three months. It is true that a great many people have been educated along these lines, but there are thousands still to be enlightened on the subject. The public must be made to realize what dental hygiene means and the benefits that will accrue to them before they manifest any great interest in the work.

Reber[18] in summing up his conclusions in his exhaustive paper on "Relation Between Ocular and Dental Diseases" has this to say, among other things: "The ophthalmologist should seek the assistance of the dental surgeon in all cases of unexplainable paralysis of accommodation, dilation of the pupil, palsy, or spasm of the external ocular muscles, rebellious corneal ulcers, phlyctenular diseases, lacrymal fistula, orbital cellulitis, abscess, caries, and periostitis and in threatening glaucoma, without apparent cause." Also Bull[19] states that "pain in the teeth of the upper jaw is by no means an infrequent symptom, in iritis and cyclitis," and he goes on to say "that toothache has been unmistakably recognized as one of the prodromal signs of glaucoma."

Not very much is said in textbooks of ophthalmology in regard to tic douloureux or trifacial neuralgia. I think it certainly comes within the province of the ophthalmologist, unless removal of the Gasserian ganglion is indicated and in that event a general surgeon should be called in. Frazier,[20] who has brought the subject up to date in a masterly and systematic way, says: "The treatment is either medical or operative, but before proceeding with any definite course of treatment one should seek for a cause, and, if possible, remove it. Particularly in these cases which are of peripheral origin may we hope to effect a cure by removing the source of irritation. It may be a carious tooth, a splinter of bone, a foreign body, a tumor, a catarrhal condition of the antrum, the ethmoidal or frontal sinuses. At the onset, at least, the treatment of all cases of trigeminal neuralgia belongs to the domain of medicine rather than surgery." I have several cases in mind which I would like to cite which I think tally well with Frazier's findings.

Case I.—Mrs. W. consulted me March, 1907; age 34; married; no children; no miscarriage; no specific history; general health splendid, with the exception of the terrible attacks of neuralgia, which almost drove her mad, as she expressed it. She complained of intense frontal headache, which seemed to radiate over the whole side of her face, including the teeth and gums of the upper and lower jaw. The supra- and infra-orbital nerves of the right side were very sensitive to pressure. In fact, she could hardly allow me to touch her on account of the "tender points." She was not able to read or sleep much at times, as the pain was so severe that she complained of not being able to see well, even at a distance. She gave a history of having had these attacks from time to time, but up to the present she had been partially relieved by phenacetine, antipyrine, and quinine. The attacks came on sometimes in the night, while she was asleep, awaking her in the midst of a severe spasm. I examined her eyes and found that she had one-half diopter of hyperopic astigmatism in each eye with the rule. Her muscle balance was normal; I gave her the prescription to correct her error of refraction, and some Warburg's tincture. She seemed to get along much better than she had before and I thought she was on the road to recovery when she came back in about four weeks with another attack. This time her face was red and spotted, showing vasomotor disturbances. She was in great pain, complicated with hysteria. I found it necessary to give her morphine hypodermatically and dilated the pupils with homatropine in order to relieve the pain. On account of the pain in the upper and lower jaws I persuaded her to consult her dentist, although she insisted that her teeth were sound. The dentist found several lesions of the last two upper molar teeth on that side. He extracted the wisdom and the last molar was repaired. From that time on she began to improve. The neuralgia grew less. The soreness in the infra- and supra-orbital nerves gradually subsided and in three months she said she felt like a new woman. I saw her six months ago and she had no return of neuralgia, but she consults her dentist every three to six months, and has a prophylactic treatment of her teeth and gums.

Case II.—Mrs. B. of New Haven, age 25, consulted me four years ago for ocular pain and neuralgia in the side of the face and head. Her general health had been splendid up to these attacks. No children; no miscarriages; no specific trouble. At times she was in frightful agony. When in one of these spasms she would take acetanilid and phenacetine in large doses, combined with whiskey, which would deaden the pain and then finally the attacks would wear off and would not return for several days, or sometimes a week. At the suggestion of a friend she consulted her local dentist before she came to me. He found no caries of the teeth and could see nothing wrong with them. When I first saw her I thought of tic douloureux, as her face was drawn on that side, which completely changed her expression. She said to me "I never expect to get my face straight again." When I applied pressure over the supraorbital nerve she fainted and was practically in a state of collapse. I gave her a hypodermic injection of morphine to control her suffering. I found her eyes about normal, one-half diopter of hypermetropia. I saw it could not be her eyes that were at fault. I advised her to consult a dental surgeon, which she did, and this is what he found. The wisdom tooth in the upper jaw wanted to come through. The jaw bone was too short, so that the crown of the wisdom tooth was turning outward and backward, and as he could not get at the wisdom tooth to extract it, he extracted the adjoining molar, which was absolutely perfect. The relief was almost instantaneous. The space in the jaw is now filled in by the wisdom tooth. That was four years ago and the pain has never come back. But for surgical interference this woman could not have lived much longer, as she was practically exhausted by the pain and suffering. According to Jelliffe[21] patients have had all their teeth extracted under the mistaken diagnosis of a dental disease, while some intractable facial neuralgias have been cured by proper attention to diseased teeth.

We come now to phlyctenular conjunctivitis and keratitis and ulcers of the cornea. These diseases

are so frequently found in school children the diagnosis is not difficult. We see them in the clinics every day and a great many of them with the red elevations on the conjunctiva, near the limbus, and sometimes these nodes or elevations extend over on to the cornea. The symptoms are: pain, photophobia, with excessive lachrymation, and sometimes mucopurulent discharge. We see these children with *their heads in their laps and moss on their teeth*. The mild forms of the disease do well with local treatment, but when the cornea becomes involved it is more serious. The ulcer may heal rapidly, under proper treatment, and generally does, leaving behind a faint nebula, which sometimes disappears. Often, however, in spite of scientific treatment we have an ulcer of the cornea which spreads in depth and width and frequently goes on to perforation and the child is maimed for life. The cause of this trouble is a strumous diathesis, inherited syphilis, adenoid vegetations, disease of the teeth, or want of proper food and proper hygiene. According to Ball[22] "there is no general agreement as to the etiology of the disease." Of one thing we are sure—all ophthalmologists know that in order to develop the phlyctenular process a suitable condition of the system must exist. In not a few cases this condition is brought on by diseases of the teeth. The patients' digestion is bad and they suffer from malnutrition and anemia. Iron and cod liver oil will not suffice to cure some of these children, who cannot chew their food properly and who are constantly swallowing bacteria, as a result of the condition of the teeth and dental caries.

According to J. E. Power[23] such men as Netter, Schriver, and other scientific investigators, have demonstrated that the dental pulp is a source of almost unlimited infection of vital parts of our system. Netter found that 10 per cent. of all mouths examined by him contained *Staphylococcus pyogenes aureus* and *Staphylococcus pyogenes albus* and that the microorganisms of pneumonia were present in 15 per cent. of healthy mouths. In these phlyctenular conditions I think the stomatologist can be of great service to the oculist, because I have seen these cases resist all kinds of medical treatment.

In the three cases which I have described to you to-night the organic lesion which produced the symptoms existed in the teeth and the signs were largely ocular. To illustrate the other side of the story, I will relate a case which came under the observation of Reber,[24] which is most interesting. A medical student, aged 24, enjoyed good health, but with obstinate dental neuralgia. A prominent dentist had pronounced the teeth all sound. For three months everything was tried, arsenic, aconite, Gross' neuralgic pills, dry and moist heat, and quinine in large doses, but without avail. He was the subject of considerable eyestrain and high exophoria (latent divergence). As he was of a very studious nature, 2° prism, bases in, were incorporated in the glasses he was wearing, and for ten years he has had no return of this dental neuralgia. This case illustrates beautifully how irritation in one branch of the trigeminal may give rise to symptoms in another branch.

Conclusions.—That diseases of the teeth should at all times be suspected as one of the causes of tic douloureux and migrane is not surprising, from their situation and intimate connection with the fifth pair of nerves, which are more frequently affected with neuralgia than the other nerves. The writer thinks that enough attention is not paid by the ophthalmologists and stomatologists to the inflammation of the various branches of the fifth cranial nerve. The oculist should catechise more of his patients in regard to the conditions of the teeth and gums and especially when they come to him complaining of neuralgic pains in the head and face. Pain referred to the distribution of the ophthalmic or maxillary divisions of the trigeminal should always lead to careful examination of eyeball as well as of the teeth. The writer holds that supraorbital neuralgia of the periodical class is a form of migrane. That the thorough study of a case of sick headache or neuralgia is one of the most difficult problems of medicine. The differential diagnosis of tic douloureux, migraine, and hysteria is not always easy. In a large percentage of persons whose headaches are without doubt due solely to eye strain and its associated local conditions the symptoms disappear promptly and permanently under correcting glasses. But in many others the results are disappointing. In this class of cases, must we look to the teeth, the nose, sometimes the ear, and also for symptoms of latent sinus disease to help us out of the difficulty. The writer wishes to point out the fact that the ophthalmologist and the stomatologist are frequently interdependent, and how important it is for both of them to be on the lookout in obscure cases for reflex neuroses that may throw some light on the subject.

Medical Inspection of School Children.—Newman points out that, notwithstanding all difficulties that have had to be met, a national system of medical inspection and supervision of school children may be regarded as now having been established throughout England and Wales. The work has only begun, but thousands of children are now receiving the consideration, the treatment, and the training which school children have previously lacked, and for a lack of which they failed, with irretrievable loss both to themselves and to the State.—*British Medical Journal.*

THE CHLORIDES, PHOSPHATES, AND SULPHATES OF THE URINE IN THE LAST STAGE OF PULMONARY TUBERCULOSIS.

By JOHN C. WARBRICK, M.D.

CHICAGO.

FORMERLY ASSISTANT TO THE OUT-PATIENT DEPARTMENT OF THE BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, LONDON, ENGLAND.

In examining the urine in a well advanced case of pulmonary tuberculosis for the amount of chlorides, phosphates, and sulphates, we would naturally expect to find some facts regarding them quite different from those found in the normal state of health; for where a destructive process has gone on for a long time in the lungs with copious exudation, sapping by degrees the strength of the body then in the last stage of this disease, the urinary findings might be expected to vary in more than one particular. During the course of a month when several urinary examinations were made in this case the results tabulated did not show much difference from those found in the normal condition of health, especially with the chlorides, phosphates, and sulphates, and in other particulars as well.

The amount of chlorides was found to be increased at each examination made in excess of the normal and in some cases registered more than three times the normal maximum daily amount in each instance, but one of the seven examinations made it about five times as much as the minimum daily amount. It has been found that in a normal state of health the chlorides can be readily increased by the taking of an excess of food at the ordinary meals each day, including especially the proteid articles in the diet, such as meats, eggs, etc., and it does not require a large amount of proteid at the meal to cause an increase in the chlorides. If larger amounts are taken of course the chlorides will increase to a greater degree; then again they can easily be decreased by restricting and reducing the regimen, more so the protein articles mentioned.

During the course of a case of pulmonary tuberculosis the amount of chlorides will be found to vary from time to time, as might be expected. They may increase a good deal for a time, then decrease at some stages of the disease, but this depends a good deal upon the regimen prescribed for the patient, the amount taken, etc. Where a great deal of tissue waste has been going on in the body for years, as in pulmonary tuberculosis, with gradual loss of strength, a large amount of food has to be taken to repair this waste and maintain the vitality of the body as far as possible, so a liberal supply of proteid food in the form of meat, eggs, etc., has been given, especially in these cases, to fulfill this want. We would therefore under these conditions look for a large increase in the amount of chlorides, as occurred in this case when proteid food was taken.

It is said by some that an increase in the amount of phosphates is an early indication of pulmonary tuberculosis, while it is stated that loss in weight is the cause of their increase. In this case, where there was a loss in weight of forty pounds, the phosphates were increased. From the tabulated report made of the seven examinations the phosphates were found to be increased beyond the maximum amount in all but one instance. The increase in nearly all of the cases was two and three times as much as the maximum daily amount.

Crystals of lime phosphates were found in the urine, but not in any large amount, and only once. Where the vitality of the tissues has been drawn upon a good deal by a wasting disease we would expect to find an increase in the amount of phosphates in the urine in larger amounts, more so in the latter stage of this disease.

This, however, may not always be the case, nor would it seem correct to say that an increase in the phosphates of the urine was always an indication of tuberculosis, for they may increase beyond the normal in health and run over the maximum daily amount without any indication of tuberculosis. In a number of cases where there was no tuberculosis present, but some debility, the phosphates have been largely increased in some instances, being more than the chlorides, exceeding by a good deal the amounts found in this case of advanced tuberculosis, while the sulphates at the same time have also been largely increased, in some cases being as much and even more than the chlorides, something rather unusual.

The sulphates at these examinations were found to be increased beyond the maximum daily amount three times, but only once to any extent, and this might not be anything unusual. Very little sediment was found at any of the examinations, and in some cases none at all; while at the others crystals of uric acid were mostly found. The specific gravity ranged from 1015 to 1025, nothing out of the ordinary for such a condition. The color of the urine was the same all the time, but changed a little at the last examination. No albumin was found in any instance.

September 30: Reddish yellow; clear; 1020; no albumin, but dark brown line; urea 1/10; chlorides, 25—387.5; phosphates, 15—232; sulphates, 1—15.5; bacteria and spindle cells.

October 6: Reddish yellow; 1024; no albumin, but dark brown line; urea, 1 5/10—15—323; total solids, 57.3—888.1; alkaline; chlorides, 55—852; phosphates, 15—232; sulphates, 10—155; sediment, none.

October 9: Reddish yellow; slightly cloudy; acid; specific gravity, 1022; no albumin; urea 1 8/10; chlorides, 50—775; phosphates, 10—155; sulphates, 1—15.5; urates in large quantities; uric acid crystals; bacteria and pus cells.

October 12: Reddish yellow; slightly cloudy; no albumin but dark line; specific gravity, 1022; urea, 1 8/10; chlorides, 30—465; phosphates, 10—155; sulphates, 1—15.5; urates, uric acid, red and black crystals, and bacteria.

October 14: Reddish yellow; alkaline; specific gravity, 1025; urea, 1 2/10; chlorides, 40—620 grains; phosphates, 10—155 grains; sulphates, 1—15.5 grains; sediment, none.

October 21: Reddish yellow; slightly cloudy; acid; no albumin, greenish line; 1020; urea, 1 4/10; chlorides, 45—697 grains; phosphates, 5—77.5; sulphates, 2—31.0; bacteria considerable; uric acid, red and black crystals.

October 29: Yellowish red; acid; slightly cloudy; 1022; urea, 2 2/10; albumin, none; chlorides, 45—697; phosphates, 10—155; sulphates, 5—77; urates; bacteria; lime phosphate.

Intestinal Crises.—H. Manon defines chronic enteropathy as the occurrence of attacks of intestinal colic with or without the passage of mucus or membrane; this is a manifestation of the gouty diathesis, the arthritism of the French authors. It is an inherited condition with favorable prognosis.—*Presse Médicale.*

POSTOPERATIVE URINARY INCONTINENCE;

URETHROPLASTIC OPERATION.*

By J. BENTLEY SQUIER, M.D.,

NEW YORK,

The history of the case which I wish to report and that of the patient which I shall present have so many features in common that I beg leave to consider them together. They illustrate traumatic lesions of the posterior urethra resulting from operations upon it. The symptoms for the relief of which the primary operations had been undertaken were trivial in comparison to those developing after the operations had been performed. In each instance an accurate diagnosis of the underlying cause of the deplorable postoperative condition was made by the use of the cystourethroscope of Dr. Leo Buerger. I doubt if any other form of urethroscope at present devised could have demonstrated the resulting lesions so graphically.

The first patient, a gentleman 52 years of age, consulted me last April with the following remarkable history: Six years previously he had developed precipitate ejaculation and pain during the act of coitus. In addition there was some pain in the posterior urethra during the act of micturition. During his youth he had had repeated attacks of gonorrhœa, but had been free from any objective evidence of the disease for ten years. Following the onset of his symptoms, he had consulted a physician who treated him by the passage of a No. 32 French sound. He persevered with this treatment for about three years, but experienced no relief. He then consulted a surgeon, who told him he had urethral strictures and advised operation, although the patient claims that at that time it was possible to pass a No. 30 French sound.

This operation, of which I have been able to find a record, was performed July 28, 1906, and is described as follows: "Through a median perineal incision the posterior urethra was incised throughout its entire length. A contracted ring was found about the bladder neck. This was stretched and the bladder drained."

The patient claims that following the operation five weeks passed before the perineal wound was healed, and then he developed incontinence of urine, which condition has obtained to the present time. For the past three years it has been necessary to continuously wear a urinal. There has been no relief of the pain during coitus or of the precipitate ejaculation.

When the patient consulted me I examined the posterior urethra by means of the Buerger cystourethroscope and the probable cause of the incontinence was revealed. A deep sulcus was present in the floor of the urethra, extending from the internal meatus out to the bulb. The posterior urethra was dilated and formed a large pouch.

I explained to the patient the condition of affairs and offered to try to repair the posterior urethra and, if possible, regain for him some control of the bladder, but definitely said that I did not know just how much I could accomplish. Having been through such a dire experience with his first operation, he demurred and requested time to consider the matter.

Shortly afterward the second patient, whom I will show here to-night, appeared at my clinic with almost the identical story. He had suffered from repeated attacks of urethritis extending over a period of six years. Although he had had no exposure to new infection for two years prior to 1909, he then consulted a surgeon for the relief of frequency of urination with associated pain in the penis and sexual disturbance similar to that of the patient already cited. The surgeon was the one who saw the previously reported case and he advised a perineal section for "strictures of the urethra," although the urethra was patent to a full-size sound. At this operation the urethra was opened through a median perineal incision, and small follicular abscess cavities were found in either lobe of the prostate; these were incised and curetted. Following the healing of the wound, incontinence of urine had developed and had continued until July, 1910, when the patient first came under my observation.

As in the former case, examination of the posterior urethra by means of the Buerger instrument demonstrated a sacculation of the urethra, extending from the anterior layer of the triangular ligament to the internal meatus. This sacculation involved the floor of the urethra and the mucous membrane showed signs of chronic inflammation.

I proposed operation to this patient and he acquiesced at once. On July 11, 1910, the perineum was opened through an inverted Y-incision, the perineum carefully dissected, and the urethra exposed from the bulb to the bladder. The urethra was found almost directly beneath the skin with practically no muscle interposed. A No. 22 F. catheter was passed into the bladder from the meatus, and a sac about the size of a horse-chestnut, which included the deep urethra, carefully dissected out. This sac was then cut away with the floor of the urethra exposing the catheter which had been passed into the bladder. The lateral walls of the urethra were united with fine catgut sutures along the under surface of the catheter, thus forming a new floor. The cut edges of the transversus perinei and levator ani muscles were dissected out of the scar tissue in the perineum and united below the urethra by chromic gut sutures, and the perineum closed. Drainage of the bladder was carried out by means of the in-dwelling catheter around which the urethra had been sewn.

The convalescence of the patient was uneventful. At the end of five days the catheter was removed, and from that time to this the patient has voided urine normally and has been free from pain. The posterior urethra has been examined on several occasions since the operation, and the healing process followed. A distinct scar line can be seen, extending along the median line of the floor of the urethra. The urethroscope shows that the sacculation was removed with the exception of a small anterior portion adjacent to the bulb of the urethra, and a trabeculated portion in the floor of the prostatic urethra near the internal meatus.

I offer these two cases as being of particular interest because of the incontinence apparently produced by the primary operations; because of the beautiful demonstration made possible by Dr. Buerger's instrument; and also as a plea for more accurate repair of the male perineum following operations upon it. We have learned that conserving the integrity of the compressor urethræ and perineal muscles is of prime importance in guarding against the possibility of urinary incontinence developing after perineal prostatectomy, therefore it would seem that similar precaution should be taken when any operation upon the deep urethra is performed through perineal incision.

SHORT TALKS WITH MY STUDENTS AND OTHERS: BEING RANDOM SUGGESTIONS FOR THE YOUNGER PRACTITIONERS.*

By ROBERT H. M. DAWBARN, M.D.,
NEW YORK.

Crepitus.—The letters composing this word, used as an acrostic, help us to remember the *Signs of Fracture:*

Crepitus.
Roentgen rays, fluoroscope, etc.
Ecchymosis.
Percussion, osteophonic.
Inability (disability).
Tenderness and pain.
Unnatural mobility.
Swelling, shortening, or other deformity.

Regarding ecchymosis, it is only of especial diagnostic value when occurring considerably later than the fracture—this being deeply placed—the blood reaching the surface in the direction of gravity. As to pain and tenderness these are of value in diagnosis chiefly when the bone is pressed upon elsewhere, producing these signs at the site of suspected fracture, *e.g.* fracture of a rib, of the fibula, of a metacarpal or metatarsal bone. Most helpful in diagnosis when the fragments remain in normal alignment and are unimpacted. Regarding inability: This refers to a sign generally believed to be peculiar to fracture of the shaft of the femur; the patient, however brave, being wholly unable to lift the thigh from the bed for some time after having received this injury. Osteophonic percussion is a sign that deserves to be better known. Often of value in the diagnosis of certain fractures. Also, in shaft-fractures, when even the thinnest fascia or other soft tissues has become interposed between the broken ends, the striking difference in pitch and intensity of sound (comparing the two sides by stethoscope while an assistant percusses) enables the surgeon, without any delay, to determine whether or not operation must be done.

As to diagnosis; as a single instance, take fracture of the femoral neck. Here the stethoscope is placed firmly against the great trochanter while percussion is made upon the anterior superior iliac spine—comparing the uninjured with the injured side, thus.

The Human Air Sterilizer.—Every additional person present in the operating room is one more purifying machine for its air; is yet another means of lessening the possibility of germs from the air falling upon the open wound in serious numbers as to the maintenance of surgical asepsis. The inhaled air, with its myriad impurities, is steadily filtered, as it were, and deprived of them during its passage from the nostrils to the pulmonary air cells. Within the nose are the moist and sticky hairs; within a portion of the larynx, all of the trachea, and the bronchi and bronchioles are the cilia, active in our defense, first catching our little enemies and then (the cilia) continually lashing upward, carrying them away from our lungs—the region of danger. Of course, additional persons breathing means just so much more CO_2 present in that room, also various more or less poisonous animal effluvia excreted by the breath. Poisons of this kind do not, however, affect the wound adversely regarding its asepsis. Microbes alone do this; and it is a well-known fact that however dusty may be the air inhaled, when exhaled it is found to be practically sterile. In a well-kept operating room just prior to operation the floor is mopped with some antiseptic solution. Otherwise, particularly in dusty seasons, and in dirty towns, each pair of shuffling or applauding feet may cause more trouble than that person's respiratory sterilizing plant can quell.

The Pretty Nearly Clean Operator.—Notwithstanding what we have said about dusty air, more or less microbe-filled, in operating rooms (see "The Human Air Sterilizer"), let us never forget that almost invariably if a clean, freshly made wound fails of primary healing it is because of actual, tangible, visible *particles of dirt* conveyed therein while operating or thereupon subsequently during dressings. Remember this: Few hands, few failures!—and this, even when the air *is* dusty. The good statistics from von Bergmann's operating room, in a most dust-laden quarter of his city and with open windows, in summer, prove that while dust is, of course, objectionable, it is usually the blunderer's poor excuse. The nearer we can approach, without unreasonably delaying the ending of the operation, to four clean hands, rubber-gloved, the wiser. (They must be clean, absolutely, because of the occasional tearing or cutting of a glove finger.) With one excellently trained player in the treble, the surgeon takes the bass, making the *magnum opus* a four-handed piece; and there will be, indeed, few or no false notes while this music lasts—certainly a triumph, remembering that the musicians are playing while gloved! To-day, with rare exceptions, infection in a clean wound should mean shame to the surgeon. Noticeably, more and more, such results are the proud possession of our brainy men—those able to master the intricacies of asepsis; to maintain unbroken that slender chain of so many links, upon the integrity of which life so often is suspended; and still to conduct with an ability which keeps pace with the march of science, a general practice. How proud are we that our cities still teem with men possessing foreheads of this remarkable facial angle! These are the pretty nearly clean operators. May they be forgiven hereafter for their crimes! Forgiveness seems to be the chief occupation of an all-merciful Deity. But, how can they ever so blunt their consciences with money thus made as to forgive themselves while on earth? Each pitiful, infected, suppurating, fever-burned, doctor-poisoned victim, like a gaunt specter, brings back to our thoughts with hideous clearness what surgery was before the surgeon knew better. He knows better now. To-day the man who operates unclean of person or appliance is unclean of soul.

*See MEDICAL RECORD, April 29, 1911.

Prophylaxis of Malaria.—Edmond and Etienne Sergent report the results of their extensive campaign against malaria in Algiers during 1908. They found that doses of 0.6 gram (10 grains) of quinine every three or six days produced the same results as daily doses of 0.2 gram (3 grains). In this manner prophylaxis was simplified; particularly in the schools the administration of quinine was attended with success.—*Annales de l'Institut Pasteur.*

Primary Paranephritic Abscesses Caused by Gonococci.—T. Migato describes the case of a patient who four years following an attack of gonorrhea was suddenly seized with manifestations of a right-sided paranephritis. After an incision and the evacuation of 200 c.c. of pus containing gonococci the patient recovered.—*Folia Urologica.*

STATE INSURANCE IN GREAT BRITAIN.

THE vast scheme of health insurance, outlined in the MEDICAL RECORD of February 25, was laid before the British House of Commons by Mr. Lloyd-George, Chancellor of the Exchequer, on Thursday of last week. This plan is so huge in its conception as to stagger the imagination, and it will embrace in its operation so large a proportion of the population, of all trades and occupations, that one can only conjecture what will be its ultimate results on the nation and on the profession of medicine in the United Kingdom.

The scheme, as outlined, embraces two measures, insurance against unemployment and insurance against sickness. It is the latter naturally that most concerns the medical man. The health insurance is compulsory in the case of every wage earner who makes less than $800 a year. Such must pay to the State a premium of 8 cents a week for men, or 6 cents for women, the employer must pay 6 cents, and the State will add 4 cents, making a total of 18 cents for every man and 16 cents for every woman employee. The State in return will give, in case of illness, an allowance of $2.50 a week during the period of incapacity, up to a limit of three months, in addition to providing free medical attendance, and in case of permanent disability will grant a pension for life of $1.25 a week. A maternity allowance of $7.50 will also be granted in addition to medical attendance. Sixty-five years is the limit of age for those entering into the scheme, but those who have entered under this age may continue in it and profit by it during life. In addition to this compulsory insurance there will be a system of voluntary insurance, the persons in this class being small tradesmen and laborers working for themselves without any definite employer. Men in this class will pay 14 cents a week and women 12 cents, and will receive the same benefits in case of sickness as those in the compulsory class. The medical part of the scheme is to be entrusted to the care of the friendly societies, but it is stated that the physicians will be better paid than they are now by these societies.

The first effect of this plan will evidently be to relieve the dispensaries and hospitals in large part of the burden of free treatment. The dispensaries will no longer give gratuitous treatment to wage earners, since the State will guarantee payment for the same, although there will still remain the wives and children (for we do not understand that the insurance covers the families of the working men) and the large army of the willingly and unwillingly unemployed. Whether the sick will still seek relief in the dispensaries, paying a small fee therefor, or whether they will be obliged to call in the physicians of the friendly societies, whether they want them or not, is not stated and very possibly is not yet decided. Until more of the details of the scheme are announced, it cannot be said whether it will materially mitigate the dispensary evil as it affects the profession at large; for it is obvious that, if the sick continue to avail themselves of the dispensary privileges, whether they pay for them or not, the mass of practitioners will derive no benefit from the plan.

The plan also calls for the expenditure of $7,500,000 by the State for the establishment of sanatoria and hospitals for the treatment of tuberculosis, and $5,000,000 will be allotted each year for the maintenance of these institutions. Another of the provisions of the scheme is the establishment of county health boards whose duty it will be to improve the sanitary conditions in their districts and to institute a campaign of education of the people in matters of health and hygiene. Regarding the value of this and of the provision for the war against tuberculosis there can be but one opinion, but time only can show whether the nation in general and the practitioners of medicine in particular will be benefited by the plan of health insurance.

The moral influence on the wage earners themselves is problematical. They will contribute less than half of the weekly premium, the larger part being given by the employers and the State, and in so far they will become objects of charity, compulsory though it may be. If that should tend to break down the spirit of independence which is the characteristic and the pride of the freeman, it would be a calamity which no amount of temporary relief of individual suffering could counterbalance. On the other hand, if the contribution of the employer is to be regarded as an increase in wages, and that of the State as something which, like police protection, every citizen has a right to demand, the spirit of independence, now wounded by the necessity of free dispensary relief, will be heightened, while one of the horrors of sickness for the deserving poor will be removed.

EDUCATIONAL STATISTICS AND THEIR MEDICAL ASPECTS.

THE physician's interest in the public schools is threefold—that of the parent, of the taxpayer, and, most important of all, of the one who must finally arbitrate upon the fundamental problems pertaining to the school life of the child, problems relating not only to the physical defects of the child, but also to the hygienic aspects of school life and educational methods. In a vague manner every practitioner is aware that a large percentage of school children have physical defects that can be remedied, that these defects interfere with their

mental progress, and furthermone that school work, in some of the antiquated methods that still prevail in the modern educational system, is itself productive of certain marked pathological tendencies in early life. The medical inspection of school children, although widely adopted, is still capable of considerable expansion and development. Problems concerning the scope and efficiency of this inspection; the proper method of compelling parents to see that their children's defects are remedied; and, finally, the problem as to the best form of administration of medical inspection, whether by boards of health or directly by the educational authorities—all these questions await solution.

The first step in this solution would be the compilation of a set of accurate statistics bearing upon every phase of this subject. The importance of such statistics has been emphasized by Frederick L. Hoffman, at the meeting of the American Statistical Association, held in Washington, D. C., April 14, 1911. Mr. Hoffman pointed out the need of more qualified analysis of the enormous amount of statistical data annually presented in the school reports of municipalities, States, and the Federal Government. He deplored the absence of really significant and conclusive returns upon some of the most important questions of educational administration and results. A full record should be kept for every child of school age as determined by the school census, which record should include all of the essential physical facts concerning the child, as ascertained by careful examination from time to time and at least once a year. Such a record should include, aside from the age and grade attained, a correct statement of the height and weight, the eyesight, hearing, and bodily condition generally. The mental record should include the essential facts of the child's progress in school, supplemented by a brief statement of moral facts in the case of defective or delinquent children. Facts of absence for cause, truancy, etc., should be noted, so that in all respects the child's record for the whole period of school life would be on file and available for subsequent needs, particularly in the case of factory employment, vocational training, higher education, etc.

With special reference to the examination of the eyes, Mr. Hoffman emphasized the necessity of differentiating between strength of visual power and evidences of astigmatism, eyestrain being one of the most serious underlying causes or retardation and ill health resulting from school life. Moreover, it was important that special reference should be paid to spinal curvature as one of the most definite indications of incipient bodily deformity more or less likely to prove subsequently the underlying cause of permanent ill health.

It is particularly gratifying to note the able manner in which this subject has been handled by a recognized authority in statistical analysis. There is considerable food for reflection in his conclusions, as follows: "There is little hope of a substantial reform in our educational statistics until the Bureau of Education of the United States Government is adequately and properly provided with a statistical force in conformity to the administration of educational departments abroad. The present totally inadequate organization of the Bureau of Education of the Federal Government is primarily defective in the almost complete absence of a well equipped department of statistics. Educational statistics are much more complicated and involved than vital statistics, to which the municipalities, States, and the Federal Government give such very serious concern. Certainly the children, who are properly called 'the best asset of the nation,' are entitled to the fullest consideration in this respect, and there is little doubt but that, if once the importance of the subject is fully realized, the United States will take a position in this respect which will place it fully on a par with other truly civilized nations of the earth."

THE PUBLIC HEALTH SERVICE.

Two bills have been introduced into the present Congress, one by Mr. Owen in the Senate, the other by Mr. Edwards in the House, increasing the pay of officers of the Public Health and Marine-Hospital Service. The bills are substantially alike in their provisions, and as neither conflicts in any way with the Owen bill creating a Department of Health, there is every prospect that this long-deferred act of justice will finally be accomplished. It is an act not of justice only, but of vital necessity. With proper pay and an opportunity for promotion the service would be as attractive to the young men of the profession as is the army, but at present it offers less than either the army or navy or the many college and laboratory appointments, and it is only because of the loyalty of its officers that it has not been seriously crippled by resignations. But there is a limit even to loyalty, and unless Congress sees fit to recognize the value of the work done by this capable body of trained scientists the service will surely suffer.

In his annual message last year the Secretary of the Treasury spoke of the needs of the service and urged that action be taken to insure its continuance. "Whatever action may be taken by Congress," he said, "now or hereafter with regard to the proposal of associating other bureaus of the Government with the Public Health and Marine-Hospital Service, it is quite clear that the usefulness of this service along the lines of sanitation and public health should be continuously developed. This service has been greatly developed under the encouragement of Congress and this development should not be interrupted. The service is in a condition to rapidly increase its usefulness and its value to the nation both on its research side and on the side of its administration. It should be placed by Congress where it can compete for its personnel with the other institutions of the country which create such an active competition for the strong men in the professional lines it includes. It is of great consequence to the nation that this service should continue to be manned as ably as possible. These are considerations entirely detached from the question of the organization of a department of health, or the bringing together of various bureaus of the Government. The continuous important development of the present

service would still be as necessary under a new association of bureaus as it is now, and development now would not in any way concern these other questions of organization."

The passage of one of these bills would take but little time from the tariff deliberations of Congress, and it would put this most efficient health service upon a sure foundation and provide the opportunity for its extension. Then, whether or not a Department of Health was created by this or some future Congress, the health interests of the country would be in safe hands.

HISTORY OF MUMMIFICATION.

The Arris and Gale Lecture for this year was delivered by Professor G. Elliot Smith of Manchester University, and dealt with the history of mummification. The lecturer drew attention to the many ways in which the ancient Egyptian custom of mummification had influenced the historical development of medical science, and also to the important part played by surgeons during the past three centuries in unraveling the technical details of the ancient art, and modifying them to meet the demands of the modern anatomist. Thus Greenhill (1705) and Pettigrew (1834) entered into this work, their chief patrons being the members of the surgical profession. The sacred Jewish and Christian literature kept alive in Europe the ancient traditions handed down by the Greeks, Romans, and Gauls, who gained their knowledge after Ptolemaic Greece became imbued with Egyptian beliefs and customs. The Crusaders, too, brought back from the Orient much Eastern knowledge, including that concerning mummification. According to Sir Thomas Browne, it was under the influence of this renaissance that in Europe "Mummy became merchandise, Mizraim cured wounds, and Pharoah was sold for balsams." Royalty and persons of high rank in Europe about this time began to be embalmed, Edward I. of England, for instance. Elliot Smith says, however, that the chief service rendered by the ancient Egyptian embalmers was that the long duration of the practice of mummifying in Egypt had familiarized the Egyptians with the idea of cutting the body, and as the result Greek anatomists of the Ptolemaic age were permitted to do in Egypt what the force of public opinion forbade in Europe, to carry on systematic dissection of the human body, and thus lay the solid foundation of an intimate acquaintance with its structure, upon which the whole edifice of medical knowledge has been, and is being, built. Elliot Smith sketched the manner of origin of the idea of mummification. In remote prehistoric times the Egyptians buried their dead in shallow graves in the fringe of the desert sands. The extreme dryness of atmosphere and soil, aided by the heat of the sun, often led to the desiccation and preservation of the body intact. When they learned this fact, that the corpse did not always "suffer corruption," it colored their religious ideas and shaped their beliefs into the conviction that the preservation of the body was the condition necessary for the attainment of immortality. An event that rendered it possible to the Egyptians to house their dead magnificently was the discovery of copper, out of which tools were made. But the construction of tombs from stone brought about another difficulty, which was indeed the *fons et origo* of mummification. It was quickly discovered that bodies placed in stone tombs underwent corruption.

Consequently, the Egyptians set themselves to supply by art that which had hitherto been afforded by nature. From time almost immemorial they had been utilizing for other purposes the materials which they afterwards employed for the preservation of dead bodies, and in this fashion came the origin and evolution of mummification. As Elliot Smith points out, the need for evisceration must have impressed itself upon the first embalmers at an early stage in their experimentation, and for this operation they made use of the flint knives to which those many centuries of experience with the operation of circumcision had accustomed them.

GRAVES' DISEASE AND ITS TREATMENT.

Dr. Robert Saundby, Professor of Medicine, University of Birmingham, England, recently delivered a clinical lecture on Graves' disease which was published in the *Medical Press and Circular*, April 5. Graves of Dublin was the first to draw attention to this condition in 1835, hence the name by which it is generally known. The disease seldom occurs before adolescence, but occasionally young children have it in an acute form. The diagnosis is easy when all the cardinal signs are present, and the only cases in which there is reasonable ground for doubt are those examples of tachycardia, without either protrusion of the eyeballs or enlargement of the thyroid gland, which are by some regarded as incomplete examples, *formes frustes*, of this disorder. It has been suggested that the lymphocytosis usually present may be of assistance in recognizing these incomplete forms. The greatest difficulty is in correctly diagnosing cases of endemic goiter which seem as if they would develop into Graves' disease, though according to Stern they should be distinguished from the latter, as the one condition never passes into the other. Some say that the blood in endemic goiter never shows lymphocytosis while others say it does so frequently. In support of the latter statement we may cite the case reported by Dlugasch in the Medical Record, October 29, 1910, in which there were fever, furred tongue, and enlarged spleen, and which was treated for some time as typhoid fever.

For long exophthalmic goiter was looked upon as being of nervous origin, but of late years the increasing knowledge of the functions of the thyroid gland has determined the question in favor of hyperthyroidism. However, as Saundby states, the overaction of the thyroid may be mainly due to the nervous system, and this view seems to have been borne out by the results which have been obtained by some surgeons after excision of the cervical sympathetic ganglia. But even the sympathetic system may not be the true starting point of the disease, and while the evidence strongly points toward

hyperthyroidism as the most prominent factor in the causation of this affection, the origin cannot be distinctly stated. Females are more subject to the malady than are males. The prognosis, according to Saundby, is fairly good provided the patient's circumstances permit of proper treatment. Working women attacked by this disease are fatally handicapped inasmuch as rest is essential, a method of treatment which is generally impossible to them.

With regard to treatment, as just said, rest is the chief necessity. This should, as far as possible, be combined with the open-air treatment and with a diet containing only a small amount of animal protein; abundant simple food with plenty of milk and eggs, but no alcohol, tea, coffee, or cocoa. Saundby states that drugs seem to have little effect and that all iodine preparations should be carefully avoided as likely to do harm. With serums the writer has had no experience.

Of course, as a physician Saundby deprecates the eagerness of the surgeons to operate and doubts the wisdom of the view taken by Sir Victor Horsley, who holds that after medical treatment has been tried for six weeks the patient should be handed over to the surgeon for operation. Furthermore, Saundby is inclined to take surgical statistics on the matter with the proverbial grain of salt and is of the opinion that surgeons often suppress their failures. He also intimates that, although the result may be satisfactory when the operation is performed by a skilful operator, it is otherwise when it is done by the ordinary surgeon. He agrees with Hale White in holding that surgery in the treatment of this disease has still to gain the confidence of the medical profession.

The Hoffmann-Werdnig Paralytic Syndrome and Myatonia Congenita.

Neurological syndromes seem to be fully as numerous as the dermatoses, the frequency of which led to the jest that dermatology was the science of names. This frequency adds to the difficulty in diagnosis and leads to the question of the polymorphism of a given disease, to descriptions of unusual types which represent hybrids, and so on. At a recent meeting of the Society for Natural Science and Medicine of Dresden (*Münchener medizinische Wochenschrift,* April 4, 1911), Brückner discussed the subject of so-called congenital and prematurely acquired paralyses of the lower extremities. A case was cited of familial paralysis of this type, two sisters being affected. The symptoms comprised highly developed muscular hypotonia of the lower extremities, paresis of some of the crural and thoracic muscles, loss of patella reflex, etc.—in general, a spinal syndrome. In one sister the symptoms included some trunk and neck muscles, while the leg flexors were contractured. The cranial nerve area was intact and the mental development normal, while the symptoms appeared after the sixth month. This latter fact should be sufficient to exclude myatonia congenita, although the resemblance is otherwise marked. By exclusion, then, the diagnosis should be the Hoffmann-Werdnig syndrome, which is the eponymic title of precocious, hereditary, spinal muscular atrophy, an affection which represents in succession hypotonia, paralysis, contracture, and atrophy. Rietschel, however, in discussion, appeared to believe that the condition was only a variation of myatonia congenita. He cited a case of the latter which was not apparent until the child was 4 years old.

Carbon Dioxide Snow in Trachoma and Nevi.

The United States Naval Bulletin for April contains an account by Passed Assistant Surgeon Gordon D. Hale, U. S. Navy, of a visit to the West London Hospital during which he witnessed the preparation of carbon dioxide snow and the treatment of trachoma and nevi thereby. According to Hale the large cylinder containing 25 pounds of liquid CO_2 is used as a generator. A folded towel made into a cylinder by rolling around a ruler is held over the opened valve at one end of the generator until filled with snow. The soft crayon of snow is then taken from the towel, broken into fragments, and pounded into a corked brass cylinder. The crayon is pushed from the cylinder and may be whittled, as a pencil, to any shape. This solid CO_2 snow pencil is of a temperature of—79° C., and will last for two hours. Morton uses it for the treatment of capillary cavernous nevi, port wine marks, lupus vulgaris, warts, moles, and trachoma. Hale witnessed the treatment of cavernous nevi and also trachoma. The crayon, shaped to cover the nevus exactly, is applied for about 40 seconds; the result being a depressed white area, which in a few minutes becomes firm, red, and raised above the surrounding skin. This is a "plastic inflammation without necrosis." A vesicle forms in about an hour, followed by a crust in a few days. The crust is allowed to come away of itself. A scar, which is hardly to be distinguished from the surrounding skin, is the final result. Morton has had great success in the treatment of the abovementioned skin affections by means of carbon dioxide snow. It may be said that the treatment of trachoma by this method is a somewhat delicate operation, several applications of quite short duration being necessary before the final result of complete disappearance is attained.

Gastric Fever.

This ancient and much discussed affection, recently renascent in medical literature, has called forth a discussion by Schneller (*Münchener medizinischer Wochenschrift,* March 7), who has had the advantage of a research into contemporary literature. Certain authors saw in the epidemic outbreak of such a malady a typhoid or paratyphoid fever. Schneller had numerous stools examined with a positive diagnosis of colibacillosis, all other affections being definitely excluded. Modern clinicians have seen in gastric fever either a typical typhoid, paratyphoid, or colibacillosis or the results of an autointoxication from gastric fermentation. Strümpell adheres to the latter view, but such a suppositious condition could hardly assume an epidemic form. This author's conception might well apply to sporadic cases, but gastric fever, as it occurs to-day, does not occur sporadically. Schneller cites one small epidemic in which no bacillary cause could be found—largely from lack of opportunity for research. In a similar episode typhoid was clearly shown to be present. From all that has thus far been learned the presumption is as follows: A sporadic case of socalled gastric fever

may be just what it purports it to be, *i.e.* the results of gastric atony and dilation, and absorption of pyrogenetic matter. But when there is any suggestion of epidemicity, we have to suspect the activity of Eberth's bacillus, *B. paratyphosus*, *B. coli*, or the specific causes of dysentery.

The Medical Expert.

The attitude of the public and the lawyers toward the medical profession in the matter of expert testimony has been for several years and is still one of mistrust. The opinion of an expert counts for very little in the eyes of the jury and even sometimes of the court, as was shown in a recent prominent case. This attitude is partly justified, though not to the extent to which it has been carried. The causes for it are not far to seek. The remedy lies within the medical profession itself. So long as the profession allows without protest any of its members to act as experts on subjects of which they have no expert knowledge, just so long will the present unfavorable opinion of such witnesses and of their testimony continue. The question has been discussed more or less during the past few years and some valuable suggestions regarding it have been made. Another serious attempt to solve the problem will be made at the meeting of the New York Academy of Medicine on Thursday of next week, announcement of which is made in the News columns. Speakers of prominence in both the legal and the medical professions will present papers and take part in the discussion, and there is every reason to hope that the result of their deliberations will be to point the way to a satisfactory settlement of this vexatious question.

News of the Week.

Suit Following Operation.—The New York Hospital has been made defendant in a suit brought by Miss Mary E. Gamble to recover $50,000, on the ground that an operation performed without her consent has crippled her right arm. The hospital's defense is that the patient did consent to the operation, that this was skilfully performed by a competent surgeon, and that following it she received the best of care.

Tuberculosis Sunday.—In Algona, Ia., April 30 was fittingly observed as Tuberculosis Day in the churches, four of the pulpits being occupied by physicians at the invitation of the pastors.

Prohibit Food Exposure.—Commissioner Lederle of the New York Department of Health, believing that the danger to the public health through the exposure of various foodstuffs on street stands is such as to demand the immediate prohibition of this practice, has directed the department inspectors to enforce the sections of the Sanitary Code covering the matter, and has called upon the Police Department for assistance. Pastry, sliced fresh fruit, perishable foods which are not cooked or pared before eating, such as plums, berries, and grapes, dried or preserved fruits, and candy must not be displayed for sale in any street or public place unless covered so as to be protected from dirt, flies, and other contamination. The exposure of meat, poultry, game (except rabbits), and fish is also forbidden.

Plague in Amoy.—Thirty-eight deaths from bubonic plague occurred in Amoy, China, during the two weeks ending May 5.

Proposed Tax on Patent Medicines.—A stamp tax of one-eighth of a cent on every five cents worth of proprietary medicines, cosmetics, and similar articles prepared under secret or privately owned formulæ is proposed in a bill introduced into the House of Representatives recently.

Cold Storage Regulations.—After visiting a number of cold storage establishments the Committee on Public Health of the New York Senate believes that it will be able to draft a bill governing the preservation of foodstuffs in cold storage which will be generally satisfactory. A bill already introduced contained a clause limiting the time for which articles of food could be kept in cold storage to six months, except by special permit. This six months' clause was objected to by the commission merchants. It is proposed to amend this so as to extend the period to ten months, except in the case of butter products, which may be kept for a year. The bill requires that all foodstuffs received by cold storage warehouses shall be stamped with the date of receipt, and gives the State Commissioner of Health power to inspect and supervise refrigerating plants. All keepers of cold storage warehouses are required to make reports before the 25th day of January, May, and September of each year as to the quantity of foodstuffs in their possession. The bill further prohibits the return to cold storage of food which has once been released and put on the market.

Hospital Force Inadequate.—The Deputy Commissioner of Charities in charge of the Borough of Brooklyn recently issued a statement charging that recent accidents in the Kings County Hospital were due to the insufficient number of attendants which the appropriation allowed for. Even the medical staff is too small, he continued, and asked for four additional internes. Complaint is also made of the inadequate protection against fire in the hospital and the lack of system in the fire alarms. At present the department has no money with which to remedy the conditions.

A Discussion on Medical Expert Testimony.—A meeting of the New York Academy of Medicine will be held under the auspices of the Section on Neurology and Psychiatry on Thursday evening, May 18. Papers will be read by Dr. Charles L. Dana on "Expert Testimony and the Medical Profession," and by Judge Clearwater on "Medical Expert Testimony." The papers will be discussed by Austen Fox, Esq., Dr. Bernard Sachs, Dr. Carlos F. MacDonald, and others.

Sanitation at the Panama Canal.—The report of the health conditions at the Canal Zone during the month of March, 1911, gives the total number of deaths from all causes among employees at 43, of which 27 were due to disease. This gives an annual average death of 10.76 per thousand, which is higher than during the past two years. The annual average death rate per thousand during the month of March in past years is given as follows:

1905	12.27
1906	37.44
1907	40.23
1908	12.47
1909	8.76
1910	8.91
1911	10.76

The annual average death rate per thousand in the cities of Panama and Colon and the Canal Zone, including both employees and civil popu-

lation, for the month of March of each year, was as follows:

1905	36.51
1906	46.72
1907	32.32
1908	20.07
1909	17.07
1910	18.33
1911	22.22

In segregating according to race, the annual average death rate per thousand from disease among employees was, whites, 3.88; blacks, 7.76, giving a general average of 6.76. The principal causes of death among employees were as follows: Chronic nephritis, 1; dysentery, 2; malaria, 2; lobar pneumonia, 7; tuberculosis, 7. No cases of yellow fever, smallpox, or plague originated on or were brought to the Isthmus during the month.

In Panama the death rate during the month was high, the increase occurring largely in the deaths from gastrointestinal diseases and from tuberculosis. Out of a total of 136 deaths, 43 occurred during the first year, and 56 in those under five years. In Colon, on the other hand, there was marked reduction in the number of deaths over that of the preceding month, and the difference is again traced to the difference in the number of deaths among children. In this case the reduction is attributed to the good work done by the district nurses. In both cities the work of sanitation, in the filling in of ditches and destruction of other breeding places of mosquitos, the extermination of rats, disinfection, fumigation, etc., has gone on as usual. The quarantine is still effective against Trinidad, where cases of plague continue to occur from time to time, and against Caracas, which is badly infected with yellow fever.

President Taft on Medical Progress.—At the triennial banquet of the Philadelphia Medical Club, held in Philadelphia on May 5, President Taft spoke on the progress made in the science of sanitation as shown by the prevention of disease in the tropical colonies of the United States, and also strikingly illustrated recently by a comparison between the health conditions among the troops now mobilized in Texas and those in the camps during the Spanish-American War. Addresses were also made by Dr. S. Weir Mitchell, Surgeon-General Stokes of the United States Navy, and Surgeon-General Torney of the United States Army. Dr. Mitchell made a plea for a Federal Department of Public Health with a representative of the medical profession in the Cabinet.

New Queens Borough Hospital.—The new hospital built in connection with the Ottilie Orphan Asylum in Jamaica, N. Y., was dedicated on April 30. The building is a one-story structure of brick and stone.

Standard of Water Purity.—The Board of Estimate of New York received on May 5 the report of Col. William M. Black and Prof. Earle B. Phelps on the pollution of New York Harbor by sewage. The board voted to appoint a committee of five city engineers to take up the question of the establishment of a proper standard of purity for the water and to arrange sewer outlets if necessary.

Bequests to Charities.—By the will of the late Charles Engert of Brooklyn the following bequests are made to Brooklyn institutions: St. Catherine's Hospital, $10,000; St. Mary's Hospital, $5,000; German Hospital, $5,000, and St. Peter's Hospital, $5,000.

The German Hospital of New York receives a bequest of $5,000 under the will of the late Thomas Achelis, who died in Bremen, Germany, recently.

Dr. Robert Doran of Albany has been appointed superintendent of the Long Island State Hospital, Brooklyn, to succeed Dr. William L. Russell, resigned. For the past year Dr. Doran has served as medical inspector for the State Lunacy Commission.

The Hempstead Hospital.—It is reported that because of a lack of support, the hospital opened a year ago at Hempstead, L. I., widely advertised as an institution managed solely by women, is to be closed within a short time.

The Nebraska State Legislature has passed a bill appropriating the sum of $100,000 for the erection of a building on the site of the Omaha Medical College.

The Jackson Parish (La.) Medical Society was organized on April 20 with the following officers: *President*, Dr. J. H. Landrene of Eros; *Vice-President*, Dr. D. E. Brown of Chatham; *Secretary-Treasurer*, Dr. A. E. Douglas of Chatham.

Alabama State Medical Association.—At the annual meeting held in Montgomery on April 21 the following officers were elected for the ensuing year: *President*, Dr. L. C. Morris of Birmingham; *Vice-President, Southern Division*, Dr. M. L. Malloy of Birmingham; *Northern Division*, Dr. Charles Lee Guice of Gadsden. The next meeting will be held in Birmingham.

Central Illinois Medical Society.—At the thirty-seventh annual meeting held in Pana on April 25 officers were elected as follows: *President*, Dr. M. P. Parrish of Decatur; *Vice-Presidents*, Dr. L. H. Miller of Pana, and Dr. E. D. Kerr of Westervelt; *Treasurer*, Dr. J. N. Nelms of Taylorville. *Secretary*, Dr. Walter Burgess of Pana.

La Salle County (Ill.) Medical Society.—The following officers were elected at the annual meeting of the society held on April 25: *President*, Dr. E. H. Butterfield of Ottawa; *Vice-President*, Dr. M. E. Blanchard of Marseilles; *Secretary-Treasurer*, Dr. A. J. Roberts of Ottawa; *Censor*, Dr. G. A. Dicus of Streator.

California State Medical Society.—At the annual convention held in Santa Barbara on April 20 the following officers were elected for the ensuing year: *President*, Dr. Thomas W. Huntington of San Francisco; *Vice-Presidents*, Dr. C. S. Stoddard of Santa Barbara, and Dr. J. R. Walker of Fresno; *Secretary*, Dr. Philip Jones of San Francisco.

The California State Association of Medical Milk Commissioners was formally organized at Santa Barbara on April 19, and the following officers were elected: *President*, Dr. Thomas McCleave of Alameda; *Vice-Presidents*, Dr. F. C. E. Mattison of Los Angeles, and Dr. T. A. Stoddard of Santa Barbara; *Secretary*, Dr. Adelaide Brown of San Francisco.

Brainerd District (Ill.) Medical Society.—At the annual meeting on April 27 the following officers were elected: *President*, Dr. E. P. Sloan of Bloomington; *Vice-Presidents*, Dr. C. W. Carter of Clinton, Dr. C. B. Caldwell of Lincoln, and Dr. R. A. Noble of Bloomington; *Secretary*, Dr. H. S. Syler of Lincoln; *Treasurer*, Dr. C. C. Reed of Lincoln.

Obituary Notes.—Dr. Henry G. Spooner of Boston, Mass., a graduate of the Harvard University Medical School in 1897, the first editor of the *American Journal of Urology*, died in the Massa-

chusetts General Hospital after a short illness on May 3, aged 40 years.

Dr. Harry Johnson Dean of Muscatine, Ia., a graduate of the Jefferson Medical College, Philadelphia, in 1890, formerly acting assistant surgeon in the United States Marine Hospital, Philadelphia, surgeon to the Nose and Throat Department of the Hershey Memorial Hospital, a member of the American Medical Association, the Iowa State and Muscatine County Medical Societies, and the Academy of Ophthalmology and Oto-Laryngology, died at his home on April 26, aged 42 years.

Dr. Henry A. Lathrop of Marshfield, Wis., a graduate of the Hahnemann Medical College and Hospital, Chicago, in 1881, and of the Medical Department of New York University in 1890, died at his home suddenly on April 23, aged 61 years.

Dr. Horace T. Cooper of Colorado Springs, Col., a graduate of the Hahnemann Medical College and Hospital, Chicago, in 1867, and a veteran of the Civil War, died at his home on April 25, aged 82 years.

Dr. James B. Morgan of Augusta, Ga., a graduate of the Medical College of Georgia in 1886, and of the New York Polyclinic Medical School and Hospital in 1892, a member of the American Medical Association, and the Georgia State and Richmond County Medical Societies, professor of anatomy and clinical surgery in the Medical Department of the University of Georgia, a member of the State Board of Health, and an ex-president of the Board of Health and Health Officer of Richmond County, and visiting physician to the Augusta City and Lamar Hospitals, died at his home after a long illness on April 23, aged 53 years.

Dr. Harriet E. Magee Fox of Chicago, Ill., a graduate of the Hahnemann Medical College and Hospital, Chicago, in 1873, died at her home on April 21, aged 69 years.

Dr. Namoen J. Pettijohn of Kansas City, Mo., a graduate of the Kansas City Medical College in 1882, and a member of the American Medical Association and the State and County Medical Societies, died at his home on April 22, aged 71 years.

Correspondence.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

HARVEIAN LECTURE—606—HISTORY, ASSOCIATION OF TUBERCULOUS AND OTHER DISEASES—FRAMBOESIA—PERNICIOUS ANEMIA AND TABES—ITEMS—OBITUARY.

London, April 21, 1911.

Mr. C. B. Lockwood undertook the Harveian lecture this year at the Harveian Society, and as subject chose "Fractures of the Patella," the surgical treatment of which has interested him so long. The requisite of treatment is a perfect result in the shortest period. Contrasting the treatment with and without operation he said in the first place there was no risk to life and limb, but in the second he had to admit that a death was not unknown, and he had known amputation to be necessary on account of suppuration. These risks were remote. The best result to be hoped for without operation was strong fibrous union, bony union being prevented by intrusion of the dorsal aponeurosis. There might be a useful limb, but with fibrous union there might be a defective limb with wasted muscles, or again wide separation, and this, too, with either a defective or useful limb. The treatment was lengthy, averaging a year. With operation, time was not long. Most important to many workmen, a patient might be at work again in six weeks. He had operated on thirty-seven patients, and advocated the open method, for details as to the fragments could not otherwise be ascertained. He made a semilunar incision on the inner side of each fragment, explored the joint, removed blood and clots, cut away dorsal aponeurosis between the ends of the bones, and trimmed the torn capsule with scissors. The drainage tube was placed at the outer side of the joint. The fracture was transverse in most cases; it might be produced by muscular action or violence. For suturing the patella he used annealed silver wire or single stout strand, only to keep the fragments in position, as he looked to bony union for strength. The knot had to be kept high so as to be out of the way in kneeling, and the loops must be arranged accordingly. Occasionally the wire had to be removed. Neville's or Mackintyre's splint was used. The drainage tube was removed in forty-eight hours, or perhaps more. He had seen skiagrams of twelve patients—all had good bony union, which he thought took three months to form. Patients had noted a slightly increased power of flexion, which did not trouble them. He considered the advantages of the operative plan outweighed the risks.

Medical gossip is still greatly occupied with 606, or some prefer to call it salvarsan; though others object to that word as unmeaning, and speak of arsenobenzol as intimating its composition to a certain degree. But amidst all the talk about it one seldom hears anyone venture to pronounce its full chemical cognomen. As to its value, most diverse opinions are freely expressed, and the printed matter about it supplies fresh views almost from day to day. But in none of the gossip have I heard an interest excited by a remark about its history, though the use of organic arsenical compounds was not unknown before the introduction of the Ehrlich-Hatta preparation. Indeed, long before then organic arsenicals had been utilized, particularly by French clinicians. True, it was Bunsen who first called attention to the cacodylates as almost nonpoisonous, whereupon physicians tried them and found them efficacious in cases in which they had used more active preparations, and were glad to feel them less risky. Passing over an interval of some years we come to the late nineties, when Professor Gautier of Paris took up the study. He found the cacodylates given by the mouth gave rise to unpleasant effects, but not when given hypodermically. In 1900 and up to 1902 he brought his results before the Academy of Medicine, Paris, showing that other arsenicals might be used either way, such as methylarsenates, benzylarsenates, and others. Further, he reported to the academy excellent results from these in secondary and tertiary syphilis. His observations were confirmed by other academicians and hospital surgeons. Atoxyl came forward later for trypanosomiasis, and was well tried in syphilis, too, as were enesol, hectine, and other preparations. If 606 eventually prove the best, it has clearly no claim to priority—is not, in fact, so much of a novelty as many seem to have imagined.

Another point with regard to organic arsenicals, they were at first largely used in other diseases than syphilis, and still more in cases complicated with tubercle, asthma, malaria, and other infections.

In reference to this question of the association of tuberculosis with the infection, it must be remembered how widespread is the bacillus, and there seems no *à priori* reason why two infections cannot coexist. At the Medical Society of London on the 13th, Mr. D'Arcy Power treated of these two infections. He said children with hereditary syphilis often showed signs of tuberculous joint disease. In young adults pneumonia or other infective disease might wake up the taint, and lesions following might become tuberculous. Tuberculous adults who acquired syphilis would have their tuberculous lesions made more active. Old persons who acquired syphilis many years previously might be attacked by senile tuberculosis. This may well be the experience of a distinguished surgeon, and the facts are such as I have often heard stated by others, but there has always seemed a doubt whether they were related as cause and effect. At any rate now, as in former days, arsenicals have been used successfully in cases in which there was no suspicion of such complication.

Nothing is more natural than that frambœsia should be attacked by 606 as soon as it became so lauded, for the organism of yaws is practically a spirochete. Strong in the Philippines, and Alston in Trinidad have found it as efficacious as is quinine in malaria. The latter found the serum of a blister from a yaws patient equally efficacious with the drug itself on other yaws cases. Further, the serum of a patient who had been so treated with the blister serum only was as efficacious. Boiling did not sterilize the serum. The serum of a healthy person gave no result. Nor did a yaws patient's own serum produce any effect on himself. Later Alston repeats that 606 is the best drug to use for yaws, it having, as shown, a curative effect. But not on yaws tubercles of the nostrils. He injected a milch goat and found the milk effective. Dr. Alston's success with the serum of a blister for yaws, has induced Messrs. Gibbs and Calthrop to try the effect of such a serum on syphilis itself at London Lock Hospital. They found the injection followed by great improvement in the patient's condition, and the effect on the Wassermann reaction comparing favorably with that under any other treatment. The serum seemed to them as effectual as intravenous infusions of 606.

With regard to other diseases, Prof. Byrom Bramwell has for many years taught that arsenical treatment had considerable value in pernicious anemia, delaying its progress and in many cases proving a temporary cure. When Ehrlich introduced 606 he determined to try it in this disease, and he has reported two cases in which such marked improvement followed as may well lead to its further employment. It must be said, however, that in both these cases Fowler's solution had been used; was, in fact, discontinued in order to test the new preparation, so the professor does not attempt to draw a conclusion except that the improvement observed justifies a thorough trial of 606 in pernicious anemia.

In tabes Dr. C. J. Macalister gave 606 to a patient whose symptoms began four years previously. (Lightning pains, loss of kneejerks, etc.) Two years before he had specific infection. An injection of 606 into the veins was followed by some transitory constitutional disturbances, but the pains, ataxia, and incoordination were greatly relieved and the patient could walk some distance. He was shown at the Liverpool Institute, where Dr. Gullan remarked that there was only what might be expected in such a case, seeing how many benefited by mercury. Dr. Warrington then said that views as to antispecific treatment of tabes were very diverse.

Sir Thomas Barlow has been reelected president of the Royal College of Physicians.

Official notice has been issued of the election of a representative member of the General Medical Council. Nominations must be sent in by the 29th of April.

The Liverpool Hospital (Fazerkerley) for Infectious Diseases was destroyed by fire on Wednesday. A gale was blowing at the time and the firemen had great difficulties, but happily there was no loss of life.

Dr. William Henry Cocker, J. P., who had been six times Mayor of Blackpool and the first freeman of the borough, died on the 14th inst., aged seventy-four. He was founder of the Antitreating League, much in evidence some years ago.

Dr. Henry Simpson, consulting physician to the Manchester Royal Infirmary and other institutions, has died in North Wales, to which he had retired, at the age of eighty-two. He had formerly taken part in public as well as medical work, had been chairman of the Sanitary Association and of the Medical Guild, as well as president of the Medical and Clinical Societies, Manchester. He qualified in 1851, took M.D., London, 1861. He contributed to the societies and journals some important papers.

Dr. George Philip Rugg, formerly of Clapham, but for some time retired, has died at Brighton, aged eighty-four. He qualified in 1850, took M.D., Aberdeen, 1856, and was for some time physician to the British Home for Incurables.

Surgeon-Major R. E. Wrafter, I.M.S., has died in his seventy-eighth year. He was in India at the outbreak of the mutiny and served throughout the campaign, as well as that of Rohilcund. He was present at the captures of Delhi, Lucknow, and Bareilly. He retired in 1888, after forty years' service.

Surgeon-Lieutenant Colonel J. S. McCutchan, late of the Royal Army Medical Corps, has also died, aged sixty-six. He took M.B., Dublin, 1865; M.Ch., 1866, and at once joined the Army Medical Service. He reached the rank of lieutenant-colonel in 1886, and retired in 1891.

Dr. J. Carne Ross died suddenly at Manchester, at sixty-six. M.D. and F.R.C.P., Edinburgh, 1882. He was at one time in the army (Black Watch) and later physician to Ancoats Hospital and West Cornwall Infirmary. He contributed to the journals on cholera and on yellow atrophy of liver, etc.

Dr. Beverley Ringer died at Stockbridge, aged sixty-six. He qualified in 1869 and took M.D., Durham, in 1891. He was medical officer to the British Consulate in Canton and to the Chinese Imperial Customs. He discovered in Formosa the "Distoma Ringeri."

OUR LETTER FROM PARIS.

(From Our Regular Correspondent.)

POTATOES IN DIABETES—EFFECT OF RADIUM IN CANCER—VOYAGE OF POZZI TO ARGENTINE AND BRAZIL—CONGRESS OF MEDICAL JOURNALISTS OF FRANCE—INAUGURATION OF THE PROFESSORSHIP OF INTERNAL PATHOLOGY—NECROLOGY—PROF. ARLOING—UNVEILING OF THE MONUMENT TO CORNIL.

PARIS, April 15, 1911.

RATHERY believes that it is an error to think that potatoes are always a useful food in diabetes; they should never be permitted in indeterminate amount

to these patients. In a series of observations the author shows that even small quantities of potatoes, such as fifty grams, are sufficient to cause a reappearance of sugar in diabetics. Potatoes should be considered as a food comparable to an indeterminate amount of carbohydrates. Marcel Labbé also thinks that we should not permit diabetics to have a large amount of potatoes. Rathery adds that each diabetic has his own way of reacting to the quantity and quality of carbohydrates, and that we cannot in advance establish any precise rule.

Guisez reports 12 observations of undoubted cancer of the esophagus treated by direct local applications of radium. In 9 cases improvement was evident, and in 3 there was every appearance of a cure. Esophagosopic examinations have permitted the action of the radium to be followed in its causation of retrogression of the tumor, while hemorrhages were lessened, and an appearance of cicatricial sclerosis was produced. Bensaude stated that radium applied under the control of rectoscopy in cancers of the rectum acts admirably on the permeability of the rectum, but does not influence the cancer itself.

At the Society of Internes, Pozzi gave a very interesting paper on his recent voyage to Argentine and Brazil. The author told of the remarkable organization of the hospitals in Buenos Ayres, in which the most recent hygienic and therapeutic methods have been adopted. Then he treated of the care of the insane left at liberty; the patients are given complete liberty, and yet escapes are exceptional. Each one is allowed to make use of his profession according to his own tastes, and they are put to bed as soon as a period of excitement begins. Pozzi then described the institute where they prepare antivenom sera after the method of Calmette. Owing to this method of treatment the mortality by snake bite has notably diminished, being not more than one-fifth as great as formerly.

The first Congress of French Medical Journalists was held at the *Faculté de Médecine,* under the presidency of Maurice Fleury, president of the Association of French Medical Journalists. The congress was occupied with a very practical and important question for all medical professional journalists; this was the conveniences that should be given to each medical writer for his work when charged with a report of a society or a learned communication. As everyone, including the readers and the reporter of a journal, have the same interest that this report should be published without omissions or errors, the journalists should be given the greatest possible advantages. The congress then considered that it would be of value to study the organization of a country which should combat the illegal practice of medicine, and to inform the physicians and the public of its dangers. On the question of the right to reproduce medical articles the congress passed a resolution that measures should be taken to prevent the unauthorized reproduction of medical articles, and that a payment of fees should be demanded of every journal which has reproduced any article.

Professor Widal, recently appointed to the chair of internal pathology, to replace the late Professor Brissaud, gave a brilliant inaugural dissertation on the advances in medicine. In this remarkable lecture he showed how the physician, always penetrating the regions beyond in the study of morbid phenomena, has evolved by successive steps from the symptom to the lesion, from the lesion to the functional trouble, and finally arrived at a knowledge of the causes and mechanism of the malady. It is in the domain of the elementary acts of life and in the world of physical chemistry that medicine will find the first education in pathological phenomena. Medicine should follow attentively the progress made by every science; a fact learned in an absolutely strange domain of science may have unexpected results; clinical medicine should take its facts from wherever they are to be found. For physicians a discovery has value from the knowledge it furnishes for the better comprehension of disease, and the weapons that it furnishes to combat it. It is because he attacks the problem of life and endeavors to penetrate the mystery that the physician studies all sciences most attentively; he would not be ennobled unless he seeks in all discoveries a means of lessening the suffering of the human race.

Professor Arloing, of Lyon, suddenly and prematurely passed away in the fullness of his scientific activity. He was one of the most illustrious experimenters of France. Veterinary, physician, doctor of sciences, he was first professor of physiology of the *Faculté des Sciences,* of Lyon. As a pathologist he has brought to science an interesting contribution in the study of autointoxications, by studying the toxicity of the sweat. It was he who demonstrated that the sweat caused by a vapor bath is bland, while that caused by fatiguing work is poisonous. In bacteriology Arloing was especially interested in the bacteria of anthrax and contagious peripneumonia of cattle. He also made studies of the sensibility of microbes and their spores to luminous rays, and demonstrated the effect of the violet rays. Finally, for some years he has been interested in the problem of tuberculosis. He believed that bovine tuberculosis is only a variety of human tuberculosis. He made important investigations on anti-tuberculous vaccination of cattle. It was these studies that he was pursuing at the time that he was cruelly removed. The death of Professor Arloing leaves a real void to French science, inasmuch as we should have expected from him new and valuable scientific discoveries.

A monument has been erected to the memory of Professor Cornil in the yard of the Medical School of Paris. The president of the Republic honored the ceremony of unveiling with his presence; he was surrounded by all the professors of the *Faculté de Médecine* and notabilities of the scientific world. We may remember that Professor Cornil, to whose memory the pious homage of his friends and disciples has raised a monument, occupied in the century that has lately closed one of the first places among the learned men of the world. It was he who in France was the true founder of pathological histology. The name of Cornil shone far beyond our boundaries. In the old as well as the new world the great French anatomist was held in great esteem. Landouzy gave a review of the scientific life of Cornil, and unveiled the monument from the chisel of Paul Richer. Under a bust of Cornil, which must resemble him, a woman in bronze, young and nude, symbolizes the ideal of truth which every *savant* reaches after. In bas-relief in the stone is seen the image of the master making an autopsy before a group of attentive students.

Albumin in Tuberculous Sputum.—Roulet states that if no albumin is found in the sputum tuberculosis may be ruled out. Albumin is excreted in the sputum not only in tuberculosis but also in all acute pulmonary affections.—*Revue Médicale de la Suisse Romande.*

OUR VIENNA LETTER.

(From Our Regular Correspondent.)

PSYCHIC ETIOLOGY AND TREATMENT OF PREMATURE ARTERIOSCLEROSIS—SYRINGOMYELIA AND CUTANEOUS DISEASE—DEATH OF PROFESSOR GUSTAV V. BRAUN.

VIENNA, April 15, 1911.

DOZENT Max Herz states that within recent years there have been recognized many cases of cardiac and cardiorenal arteriosclerosis, which for years torment the patients with stenocardiac attacks. On the other hand, the cases of angina pectoris with their tragic outcome have become less frequent. In response to a questionaire concerning arteriosclerosis which Herz sent to several thousand physicians, it was noted that psychic trauma and physical work played a large rôle in the etiology. A psychic factor is observed in the case of the mental depression associated with disturbances in the coronary circulation. It is the aim of therapy to combat this depression, particularly the hypochondriasis to which the patient is subject; the restriction of diet should not be carried too far, in order not to increase the patient's discomfort, while the suggestive value of physico-therapeutic measures should be relied upon. The large percentage of cases of arteriosclerosis among physicians is attributed to the mental stresses to which the latter are subject.

Otto Kren reports a case of a male, 25 years old, who presented typical manifestations of syringomyelia associated with cutaneous lesions. The latter consisted of unmistakable dematographism and the formation of wheals following the finest needle-pricks, and of severe lesions in the skin of the hands. In addition to atrophy of the muscles and of the bones of the terminal phalanges, there were ulcerative processes at the finger-tips, consisting of punched-out ulcers with a horny border, similar to perforating ulcers. The nails were claw-shaped, bent downward, and ecchymosed. On the palmar aspect of the third metcarpophalangeal articulation there was a callous formation. There was on the ball of the right thumb a similar callosity about the size of a five-crown piece. It is well known that cutaneous lesions are associated with syringomyelia; as a rule, they are the result of the diminished or absent sensibility of the skin, and of traumatism and infection. In the case reported the lesions were due to trophic disturbances.

At the ripe age of 82, there died, January 8, Hofrat Professor Dr. Gustav v. Braun, a man of rare and brilliant attainments. The younger brother of Karl v. Braun, he was born at Zistersdorf in 1829, studied at Prague and Vienna, and in 1853 received at the latter city the degrees of doctor of medicine and master of obstetrics. After a short incumbency in the surgical clinic of Professor Schuh, he was made assistant in the obstetrical clinic of Professor Klein, succeeding his brother Karl, who had been called to Trient. As early as 1856 he became privat dozent, and at the age of 30 he was designated professor extraordinarius and, following Klein's death, became director of the clinic, and in 1862 filled the chair of obstetrics at the Joseph Academy. When, in 1873, the latter was closed, the obsterical school, of which Späth had been the head, was separated from the second obsterical and gynecological clinic, and Gustav v. Braun was made ordinary professor and chief of the clinic. In these capacities he continued until his 71st year, when he retired from his academic positions. He still kept up his active work as member of the chief board of health, and in the scientific proceedings of the obstetrical and gynecological society, in whose foundation he had participated. Besides his clinical and didactic service and his enormous private practices, Braun carried on valuable scientific investigations, particularly in the domain of cesarean section.

An Analysis of Forty-Six Cases of Prostatectomy. L. Davis.
A Case of Pemphigus Chronicus Vulgaris of the Oral Cavity and Larynx. R. A. Coffin.
Acute Toxemia Caused by Injection of the Throat by the Colon Bacillus. C. B. Faunce, Jr.

Men, Manners, and Medicine.—R. M. Green describes some of the details of environment which determine the manners, the habits, and customs of thought, the cultural background of physicians in England. As one meets them, older and younger, they are men of generalized education, not solely concerned with science or with money-getting, keen in the pursuit of the problems of their profession, but with a broad sympathy for other human interests as well. Their manners are something those of the scholar as well as the physician, and medicine to them is more than a means of livelihood or an abstract science. And this humanistic habit, these manners that make the man, they have acquired from the nature and surroundings of their preliminary and professional training.

Climatic Treatment of Tuberculosis.—G. Hinsdale believes that for the majority of incipient cases, where the patient can well afford it, life in a selected locality in the West offers the best prospect of cure; but that for Eastern patients a period of training in an Eastern sanatorium is highly desirable—the first and most important stage in beginning any climatic treatment. Dryness, sunshine, and altitude are features of the best climate, but they decidedly disagree with some patients when presented in extreme doses, as in some of the Southwestern resorts.

"Common Colds."—J. A. Honeij concludes that preventive methods are essential in dealing with common colds. Better working conditions, pure air, even temperature, proper ventilation, and the proper amount of humidity are important factors. Nourishment, general hygiene, and proper clothing are necessary precautions, as in guarding against all other diseases. After the onset of a cold, proper diagnosis is essential to ascertain whether the cold is infectious. Individuals suffering from infectious colds should be isolated.

Prostatectomy.—L. Davis continues his analysis of forty-six cases of prostatectomy.

Pemphigus of Mouth and Larynx.—R. A. Coffin reports a case of pemphigus chronicus vulgaris that involved extensively the oral cavity, epiglottis, and larynx for over four years before finally making its appearance on the skin.

Colon Bacillus Infection of Throat.—C. B. Faunce reports the case of a woman who presented the typical clinical picture of tonsillar diphtheria. Cultures were negative so far as the Klebs-Loeffler bacillus was concerned, but showed pure growths of colon bacilli. The picture produced in the patient by the infection was that of an acute toxemia, as shown by the high temperature, marked prostration, severe headache, chilly sensations, and lumbar pains. Evidently this organism was either especially virulent or the resistance of the patient lowered, so that the tissues fell easy prey to the bacterium. How the colon bacillus came to be in the throat was a matter of conjecture.

Uses of the "Cold Cautery," Especially in Dermatology. L. D. Frescoln.
Is Antitetanic Serum a Factor in the Cure of Tetanus? J. C. Kennedy.

Therapeutics of Syphilis.—V. C. Pedersen emphasizes a number of important points. There are three broad types of the invasion of syphilis: the benign, the relapsing, and the severe forms. The treatment of syphilis is not merely a matter of medication, but also a matter of management. In the general management of syphilis better progress is made if the so-called alkaline measures of treatment are applied. The diagnosis should include not only the recognition of the specific infection, but also the estimate of its effect upon the body of the patient. Careful physical examination is necessary. The author discusses the various methods of treatment, including salvarsan.

Salvarsan Therapy.—A. G. Rytina states that salvarsan possesses wonderful symptomatic efficiency; one injection is equivalent to at least four or five months' course of combined mercury and potassium iodide treatment. Intravenous injection is practically harmless, gives rise to neither pain nor complications, and is productive of better results than are obtained by either the subcutaneous or intramuscular methods; furthermore, it produces results more quickly than can be attained by either mercury or potassium iodide, and very often cures lesions where heroic doses of mercury and potassium iodide have failed. On account of its wonderful spirillocide action, syphilis will be less prevalent and there will be less liability to tertiary manifestations and the development of parasyphilis, after the proper method of treatment has been fully ascertained. Whether this be the "chronic" injection treatment of Kromayer, the combination method of Iversen, the triple intravenous injection method of Weintraud, the triple injection plus mercury method of Neisser, the injections every forty days as long as the Wassermann reaction persists, or the reinforcement of injections by courses of mercury and potassium iodide, for six months to two years, only the future can tell.

Salvarsan.—F. Wise discusses the dangers associated with and the contraindications of this drug.

Salvarsan Given Intravenously.—E. G. Ballenger describes his apparatus for the intravenous injection of salvarsan.

Intravenous Injection of Salvarsan.—W. R. Thomson describes the advantages of this method of administration.

Rabies.—G. G. Rambaud states that in the diagnosis of this disease the laboratory has "made good," and when an uncertain or no diagnosis was made during the life of an animal submitted for examination it can, within a few hours, in 90 per cent. of the cases, clear up the case. The Negri bodies, when present, prove in 100 cases out of 200 that the animal was rabid. Their absence means that, with a probability of 90 per cent., the animal was not rabid. Then experimental inoculation will settle the case within twelve to twenty days. The bite of a rabid dog is harmful to man in proportions varying from 10 to 90 per cent., according to different conditions.

Treatment of Hiccough.—H. D. King defines hiccough as an involuntary sudden contraction or descent of the diaphragm, whereby a vacuum is formed in the chest, into which outside air attempts to rush, but is denied entrance by the sudden closing of the glottis, the impact causing a characteristic sound. The attack, which is often regarded as of small moment, may become one of the greatest importance in certain acute or chronic diseases. The causes are: A. Gastrointestinal; irritative, inflammatory, and reflex. B. Specific, or secondary to abdominal or diaphragmatic abscess, gastric carcinoma, etc. C. Neurotic or reflex. D. Miscellaneous causes, as alcoholism, overeating, cardiac trouble, pregnancy, etc. Among the many popular remedies, the taking of large draughts of water while holding the breath seems to have the strongest hold on popular favor. If this proves futile, musk, in a dose of five to ten grains in starch water, should be given a trial. Treatment should be directed against gastrointestinal causes. In the severe cases any of the following procedures may be resorted to with success: Lavage, passing of esophageal sound, prolonged pressure over the abdomen and epigastrium, forcible traction on the tongue, abdominal massage, constriction around the lower thorax, cold pack, hot packs, applications of blisters on each side of the cervical spine over the roots of the third, fourth, and fifth nerves. Of the internal remedies, the number is legion and only a trial can prove their worth. The following have been suggested and used: Nitroglycerine, cocaine, spirits of chloroform, codeine, tincture of capsicum, spirits of camphor, tincture of valerian, amyl nitrite, jaborandi, asafetida, the bromides, and numerous other drugs. Morphine, hypodermatically, is not of much value, as the effect is shortlived.

"Cold Cautery" in Gynecology.—L. D. Frescoln concludes that carbon dioxide locally gives definite inflammatory reaction, a stimulating action, destructive action with slight resulting scar, and immediate destruction or cauterization under prolonged exposure and strong pressure. Chronic elevated lesions are those that seem to respond to this treatment. Lesions that have become infected respond less readily. It has been found also that often a combination of the forms of treatment will give results when a single method will not. Lupus erythematosus is said to respond extremely well, but not lupus vulgaris. Proliferating carcinoma, not deep, responds; ulcerating epithelioma (rodent ulcer) does not. Further study is needed on this form of treatment to exhaust its possibilities.

Value of Tetanus Antitoxin.—J. C. Kennedy states that, although the exact value of the serum treatment of tetanus is still undetermined, it is his belief that tetanus antitoxin neutralizes to some extent the toxins of the tetanus bacillus.

Rice and Beriberi.—By V. G. Heiser. See MEDICAL RECORD, April 15, 1911, page 689.

Premenstrual Fever.—L. Kessel finds that in the 100 case of pulmonary tuberculosis, in all stages of the disease, that he reports only two uncomplicated cases of premenstrual fever occurred. It has been shown in a large series of cases (2,000) that similar rises may occur in a large number of unrelated conditions. The proportion in which the rises occurred in the author's cases was out of all proportion to that assigned to it in literature; so he is

forced to conclude that far too great stress has been laid on the incidence of premenstrual fever in tuberculosis. The theory of Riebold, which refers to the relation of ovulation to premenstrual fever, in dormant disease, is one which commends itself, but for which sufficient evidence is not yet present.

Lead Poisoning.—A. Hamilton notes that white lead works are admittedly dangerous and steps toward controlling the industries have been taken in Illinois, but this is not true of lead smelting, in which a large proportion of the workers suffer if they remain long at the work. Another very dangerous occupation is the manufacture of storage batteries, and the printers' trade is found to be far more dangerous than it ought to be. Mechanical or commercial artists are not usually supposed to be in danger of lead poisoning, but Dr. Hamilton discovered sixteen cases among them. The use of the "air brush" and the habit of putting the pencils or brushes in the mouth are ascribed as causal factors. As regards the diagnosis of lead poisoning, the author points out that the idea of a selective action on certain muscles is probably fallacious and that overwork is more a factor. The basophilic granulation of red corpuscles is losing credit somewhat as an absolute sign, and there is a wide difference of opinion as to the finding of lead in the urine. Plumbism is too variable in its development for any one sign to be regarded as diagnostic. A combination of symptoms, slight in themselves, but occurring together, is more apt to be diagnostic of the early stage. The absorption of lead is mainly through the digestive tract, though dust is important and the first requisite in prophylaxis is its abolition. If dust is abolished and workmen not allowed to eat lead they can work with comparatively little risk. The habit of chewing tobacco while working in lead is forbidden by law in Great Britain and Germany. Another cause of frequency of lead poisoning mentioned is the unskilled casual laborers passing in and out of the lead trades; the number of these has been shown by European statistics markedly to influence the number of cases of lead poisoning. The regular medical inspection which is required by law in most foreign countries makes it possible to detect and remove early and susceptible cases and to avoid a threatened attack of colic. This has been voluntarily introduced in some Illinois factories and legislation to make it compulsory is now pending in Illinois.

Animal Experimentation and Syphilis.—J. W. Churchman states that prior to 1903 animal experimentation had practically not been applied to this subject. In that year the susceptibility of certain animals to the disease was discovered, and the fact that the infection could not pass through a Berkefeld filter was soon afterward discovered; in 1895 Schaudinn and Hoffman's epoch-making discovery of the spirochete causing the disease was made and inaugurated a new era in the history of syphilis. Hardly less important was the discovery of the test of complement deviation. The last contribution made by animal experimentation is Ehrlich's discovery of a specific drug.

Tuberculosis.—G. H. Kress has devised a convenient table presenting a system of numbering dilutions of tuberculin.

College Hygiene.—M. P. Ravenel and W. D. Frost discuss the hygienic needs of the higher educational institutions, and give a history of the hygienic movement at the University of Wisconsin.

Thenar Atrophy.—J. E. Donley states that the distinguishing marks of peripheral neural atrophy of the thenar muscles are: Precise limitation of atrophy and motor defect to the opponens pollicis, abductor pollicis, and superficial head of the flexor brevis pollicis; reactions of degeneration confined to these muscles; absence of subjective sensory changes; absence of objective sensory defect; absence of fibrillary twitching, and rather rapid onset of atrophy and weakness.

Oriental Sore.—S. T. Darling and R. C. Connor report a case of this condition in a native Colombian, which case was the third one found to date and illustrated certain peculiar features of the disease: the chronic eroding character of the ulcer, its location on an exposed part, the presence of a second ulcer nearby (autoinoculation), the history of a fly-bite, and the difficulty experienced in this case in finding the pathogenic agent.

Exercise Machine for Poliomyelitis.—M. Strunsky describes a miniature Zander machine, which is portable and cheap, and can be attached to a table or chair.

Correction of Nasal Deformity.—W. W. Carter reports three cases of depressed deformity of the nose that he has treated successfully by bone transplantation. The bone selected by him in these cases was the rib, which is easily removed, especially about the middle of the ninth rib, where the muscular covering is very thin. The shape and structure of the rib also favor its use. When the bone is split and the cancellous tissue removed, the strips of compact bone can be easily shaped to fit the deformity, and, if needed, several layers of bone can be superimposed.

Potassium Permanganate as a Hemostatic.—L. Buckle reports a case of persistent bleeding following a ritual circumcision in an infant. After all the usual hemostatics tried had failed, powdered potassium permanganate was applied to the wound, and the oozing immediately ceased and did not recur.

Idiosyncrasy to Aspirin.—G. B. Gilbert reports a case of giant urticaria and asthma following the administration of five grains of aspirin to a patient that had been subject to attacks of asthma.

Pain and Abscess Following Use of Salvarsan.—B. C. Corbus attributes the pain and induration following subcutaneous injection of salvarsan to the sodium hydrate. In order to make the solution alkaline, he uses a 2 per cent. solution of sodium hydrate instead of one of 15 per cent. strength, as recommended.

An Unusual Case of Pericardial Effusion. J. Rae.

Sensibility of the Alimentary Canal.—A. F. Hertz states that the alimentary canal, from the commencement of the esophagus to the junction of the rectum with the anal canal, is completely insensitive to tactile stimulation. It is probable that the sensation felt when hot and cold fluids are swallowed is produced in the esophagus. The whole of the latter is sensitive to thermal stimuli, and the localization is extremely accurate, particularly in the case of heat. The gastric mucous membrane is completely insensitive to thermal stimuli. This is also generally true of the large intestine. Contrary to the common belief, contact with free hydrochloric acid is not the direct cause of the pain in gastric and duodenal ulcer. The tension exerted from within on the circular muscle fibers of the stomach is the cause of the sensation of fulness. Under pathological conditions the tone of the stomach may be permanently increased and complete relaxation may be impossible. A comparatively small quantity of food will then cause an uncomfortable sensation of fulness, which can only be prevented by eating very slowly.

The Declining Birthrate.—F. E. Fremantle discusses

the problem as to how one can save for the individual, the State, and the whole world the benefit of Nature's full human harvest. Such physiological causes as there may be for this decline are beyond one's ken, and for the present, if they exist at all, must be left alone; however serious to those they affect, to the nation they are of minor importance. The chief and obvious factors are three in number: (1) the rational, due to knowledge of methods of prevention and ignorance of its results; (2) the economic, due to the inventions of the Victorian era and the consequent freedom of communications and competition in every phase of life, and (3) the moral, due to indulgence and lack of discipline. With the economic and moral factors medical men have only indirect concern. But against the rational factor we are responsible for the remedy. Both personally and in public we must insist, as no other profession can, on the paramount value of nature's own methods and checks, on the serious danger resulting from celibacy, from prostitution, from interference with the normal married life, from disregard of nature's seasons; and not least on behalf of all concerned on the healthy influence, the gaiety, and the ultimate economic value of a well-stocked nursery.

Cerebral Fat Embolism.—R. J. Godlee and G. E. O. Williams note that of nineteen victims of a recent railway accident, of whom four died, three developed at different intervals after the accident cerebral symptoms. In two of these post-mortem examination proved that the unusual symptoms were associated with, if not due to, cerebral fat-embolism. The following points of special interest are noted: 1. The difference in the extent of the original injury in two cases. Whereas one might have expected fat-embolism to occur in the case where there were several fractures, some of which were of a crushing nature, there was nothing about the simple fracture in the other case to suggest the likelihood of its occurrence, or at all events of its causing any grave symptoms. 2. The absence of dyspnea or other symptom of pulmonary embolism in one case and the fact that the other patient only complained that his bandages felt tight. 3. The resemblance superficially of the condition to that of cerebral compression, but only superficially, because the characteristic pulse of compression was never observed. There were never any signs in the nervous system pointing to a localized injury to the brain.

Ocular Conditions in Medical Cases.—J. Taylor discusses the following: conditions of the pupil; conditions of ophthalmoplegia externa; changes in the optic nerve; retinal changes; and hemianopia.

Direct Bronchoscopy.—H. Tilley reports two cases showing the value of this method for the detection and removal of foreign bodies impacted in the lower air-passages.

Ionization in Colitis.—J. C. Webb reports good results following this method of treatment in thirteen out of fourteen cases in which it was tried. The treatment is based on the principle of ionization, whereby the passage of a constant current propels the basic ions of any salt in solution from the positive toward the negative pole. If, therefore, the rectum and colon be filled with a solution of the required salts, and connected to the positive pole of a source of constant current, the negative pole being on the abdomen and back, and a current be passed, there will be a passage of the metallic base of the salt into or through the diseased mucous membrane toward the negative pole. The solution employed for this purpose was one of zinc sulphate.

Lymphangioplasty for Ascites.—R. A. Stoney and T. G. Moorhead report a case in which the introduction of artificial silk lymphatics, according to the method suggested by Sampson Handley in his Hunterian lectures for 1910, has been followed by the disappearance of the ascitic fluid.

Treatment of Measles.—R. Milne advocates the treatment of measles along the same lines that he has recommended for scarlet fever, namely, non-isolation; and the use of pure eucalyptus oil gently rubbed in, morning and evening, all over the body. Afterwards this is repeated once a day until the tenth day of the disease. The tonsils and pharynx are swabbed with 1 in 10 carbolized oil every two hours for the first twenty-four hours, very rarely longer.

Acute Hemorrhagic Pancreatitis.—E. Gillespie reports a case of this condition, successfully operated upon.

A Case of Pericardial Effusion.—J. Rae reports an unusual case of this condition, of tuberculous origin, in which drainage of the pericardial sac was performed. Death occurred from tuberculous meningitis.

Arteriosclerosis and the Kidneys. Sir Clifford Allbutt.
On the Interdependence of the Circulatory and Respiratory Systems. I. McKenzie.
Hepatic Distomiasis (Sheep Rot) in Man. G. R. Ward.

Kinks in the Causation of Chronic Intestinal Stasis.—W. Arbuthnot Lane states that owing to the erect posture, there exists an almost constant tendency, except for an average of seven hours out of twenty-four, to the falling of the viscera in the abdomen. This results in the formation of kinks at certain fixed points. One of these is the pylorus, occlusion of which causes defective drainage of the stomach, with alteration in its chemical contents, which becomes a primary factor in the development of ulcer of the stomach. Another kink occurs at the duodenojejunal junction, producing distention in the duodenum, and pain and tenderness in the latter, arising when food enters it from the stomach. The pain is relieved by the supine posture. The duodenal ulcer gets well very rapidly in this position, since the cause of its production, namely, the kinking of the pipe, ceases to exist while the patient is in this posture. The gastric ulcer, on the other hand, gets well very slowly, since the strain upon it is only partially relieved. The curative effect in duodenal ulcer of gastro-enterostomy is really the result of fixation of the commencement of the jejunum to the stomach in such a manner that it can no longer fall vertically downward and kink at its junction with the duodenum. The next weak spot in the drainage system occurs at the end of the small intestine—the ileum. The cecum, which is the blind extremity of the cesspool, tends to become displaced into the true pelvis, which it occupies to the inconvenience of other important structures. Supporting bands are formed external to the cecum. One of these secures the appendix and frequently kinks it, with the result that the portion beyond the kink distends and produces symptoms of varying severity, which are comprised under the term "appendicitis." Other kinks develop abruptly at the hepatic and splenic flextures of the colon. These are exposed to irritation and are consequently liable to malignant disease.

Short-Circuiting in Chronic Intestinal Stasis.—H. Chapple presents a study of the life histories of fifty cases of chronic intestinal stasis, which was first described and treated in its surgical aspects by Arbuthnot Lane in 1901. The subjective symptoms in these cases were severe and frequent headaches, nausea, anorexia, loss of weight, markedly cold hands and feet, mental apathy, constipation, a constant foul taste in the mouth, attacks of abdominal distention, general muscular pain, and a loss of freedom in the movements of the joints. Physical examination showed skin-staining, the degree of which varied directly with the distance of the site of obstruction from the stomach: and changes in the breasts which in the early stages are similar to those usually described as chronic mastitis

and later as cystic degeneration. The abdomen was tender on palpation; the cecum was, as a rule, a pelvic organ and much dilated; the transverse colon was usually palpable and hung below the level of the umbilicus, and its middle portion was found to be in the true pelvis. The operative procedure adopted in these cases is as follows: The abdomen is opened by an incision through the left rectus, and the viscera are examined. The lowest point of obstruction is found, and the ileum is divided and its distal end invaginated by a purse-string suture, and then the proximal end of the ileum is implanted laterally into the lowest accessible portion of the iliopelvic colon. The first thing noticed by the patients is usually that they move their limbs more easily, and they tell one that they feel as if a cloud had been lifted from them. The headaches, the nausea, the vomiting, the depressed circulation, the mental lassitude and apathy are gone. The foul taste goes from the mouth, and the skin staining clears up at a remarkable rate. The constipation is in many cases cured, and is in all now easily under control.

Arteriosclerosis and the Kidneys.—Sir Clifford Allbutt states that the arteriosclerotic kidney is a local phase of general arterial disease, producing in the kidney just the alterations which it produces in other organs of the body—alterations which need not amount to anything very grievous, as they are compatible with many, if sere and yellow, years of life; but that granular kidney, on the other hand, is some form of progressive inflammation of the gland as such, the structure essential to its function being attacked. In this fatal disease arteriosclerosis appears in two ways—primarily and essentially in the fine arterioles of the organ itself; secondarily and later in the systemic arteries, as the effect of strain under the excessive arterial pressures in which granular kidney is always and regularly involved. The arteriosclerotic kidney, on the other hand, if it may arise in the later stage of strained arterial systems in hyperpiesis, the presclerotic stage, is most common in the decrescent form of arteriosclerosis.

Interdependence of Circulation and Respiration.—I. McKenzie states that the observation of over 1,000 cases of measles, whooping-cough, and diphtheria has led to the conclusion that where an intercurrent bronchopneumonia extends over a period of a fortnight the progress of the case has, as a rule, been complicated by the occurrence of collapse; in the case of nonrecovery the patient has succumbed not to the toxic products of the infecting organism, nor to the noxious products of inflammatory decomposition, but to the severe mechanical strain which has been put on the heart. This strain is due to failure of the accessory pumping assistance of normally expanding lungs, and the almost constant occurrence of varying degrees of cardiac hypertrophy in such cases is very strong evidence in support of that contention. Similarly in acute rickets and in subsequent chest deformity there is great liability to collapse of lung tissue, more especially in the event of the occurrence of an intercurrent bronchitis. Such collapse enhances the disability to which the respiratory mechanism is exposed by the presence of soft rachitic ribs or a distorted and narrow thoracic cavity; the double embargo thus placed on the heart leads to a hypertrophy which can maintain a compensation only over a limited period except under the most favorable conditions. The period of childhood and even of adolescence may in cases of chest deformity be occasionally survived without any considerable degree of inconvenience, and the result of excessive cardiac strain may manifest itself first in adult life.

Hepatic Distomiasis in Man.—G. R. Ward states that only thirteen or fourteen authentic examples of this condition, which is also known as sheep rot, have been reported in man.

Action of Salvarsan on the Ear.—Haike and Wechselmann have studied the therapeutic action of salvarsan upon syphilitic affections of the ear, together with the collateral action of the drug under such circumstances. It is known that syphilis may act so rapidly on the ear that irreparable damage can be set up before therapeutic effects can be obtained. Aside from such cases, however, there seems every evidence to anticipate favorable results from salvarsan upon the ear; and this assumption is justified by the reports made to date by the authors and others. The authors decide that salvarsan exerts the same favorable action on syphilis of the ear as in syphilis of other organs, and that it gives good results equally in all three stages of the disease as well as in its hereditary form. In regard to alleged unfavorable collateral effects from salvarsan, none have yet been reported which could not have been caused by lues alone. The neuro-relapses seen are not due to a specific neurotropic action of the drug; for in all relapses seen by the authors the middle ear suffered along with the nerve apparatus. The authors believe that the usual tertiary affections of the acoustic nerve and labyrinth may appear in the early stages of cases treated by salvarsan, a phenomenon which has parallels and has been explained in various ways.

Pathogenesis and Therapy of Gallstone Disease.—Mayer strives, in a lecture upon this subject, to bring theory into harmony with therapeutic results. He admits that but little progress has been made in this direction, because of our ignorance of the physiology of biliary secretion, and of the essential causation of the malady, which is doubtless deepseated—a constitutional anomaly. The author has for years made use of calomel in biliary colic associated with continued high fever. He gives half a gram per diem at the most, divided into eight doses. The results are often brilliant, fever and colic subsiding in one or two days. The mode of action of calomel is not clear. It revives the old controversy as to the cholagogic action of calomel, which has long been decided in the negative. The author in his calomel treatment lays down as one rule that the drug must be given until a typical calomel stool is produced, irrespective of other considerations. In discussing so-called cholagogues, the author mentions the free injection of water—always hot and upon an empty stomach. The result is a liquefaction of the bile. Cold drinks are strictly contraindicated in gallstone disease. About half a liter of hot water should be taken before using and 200 c.c. on retiring, with small amounts during the day. There are no true cholagogues and no specific diet for gallstone disease. Meals must be small, but may be frequent.

Treatment of Paresis with Nucleinic Acid Injections.—Loewenstein reports adversely upon this method, which he has been testing very thoroughly on fifteen paretics. In eleven of the cases the remedy showed itself quite inert, and in three of these cases death has already taken place while the other eight are in the terminal stage. In two cases improvement resulted, but this seemed to have already begun spontaneously, or under the influence of previous treatment. These remissions differed in no wise from those which develop under other circumstances. The remaining two cases could not be controlled, as they disappeared from observation.

Fifty Years of Aphasia Study.—Heilbronner sums up the results of half a century of research into this subject as follows: The fundamental facts established by Broca and later by Wernicke have stood the test of time. Clini-

cally the progress in our knowledge of speech disorders has been great, and a series of valuable anatomical data has been furnished. The hope of increasing exactness in localization appears to be justified, but the further anticipation of penetrating into the relationship between the physical and psychical cannot be entertained. All the work done jointly by other observers does not equal that produced by Broca and Wernicke. Much of the former has been in vain, or has led to erroneous views, but it cannot be said that the entire amount of research outside the work of the two pioneers has been misdirected. Many details have been built up on the foundation originally established. Liepmann's studies on apraxia have thrown much light on aphasia.

Alleged Characteristic Urinary Test for Paresis.—Stucken states that the reagent known as liquor Bellostii was first used for the urinary diagnosis of helminthiasis, but the significance of the reaction was later denied for this affection although asserted to be positive in certain cases of acute febrile disease. Finally Butenko made the claim that the reagent was of much value in paresis, especially in differentiating the latter from other affections of the nervous system. His findings have been corroborated by others. The author tested twenty-seven paretics for the reaction and found that the latter cannot be regarded as specific for paresis. All but six cases did indeed react positively, but the percentage in a few cases of cerebral syphilis and tabes was 100. A good percentage of positive results was obtained in arteriosclerosis, epilepsy, alcoholism and a fair one in some of the insanities. Positive results were also obtained in cancer, tubercle, diabetes, etc. It therefore appears that the liq. Bellostii is of no value at all as a clinical reagent. The only conclusions to be drawn from its occasional or common occurrence in various diseases are as follows: In many urines from both sick and apparently sound individuals a blackening occurs in the precipitate formed when the said urine is heated with a solution of mercuric nitrate in weak nitric acid. The black color is doubtless evidence of a reduction. The reacting substances is stable toward heat, very sensitive toward acids, and insoluble in ether. Its relations to disease are obscure, and the subject is being further investigated.

What Was the Plague of Thucydides?—It has generally been assumed that this was the bubonic plague, brought from Egypt to Athens. Kanngiesser, having studied all references, lay and professional, to the plagues of that epoch, thinks he has made out a better case for typhus. He has naturally studied all accounts of the latter since its first recognition. This affection, like the classic plagues, is known to have been pathogenic to dogs. Another point in common is the circulation. Unlike most severe febrile affections, both typhus and the classic plagues presented a relatively cool surface, and the circulation was often so much arrested that gangrene of the extremities took place. Inwardly, however, the patients burned up with fever, and thirst was unquestionable. Infection was direct from man to man. This also suggests the pulmonary form of the bubonic plague, but the latter seems to be excluded by other symptoms. For example the patients lived for eight or nine days on an average.

Colitis Gravissima.—Baumstark states that this condition is by no means rare and reports a case in detail. The patient, a young woman, went through an attack of colitis gravis in 1908 at Bad Homburg, where she was treated by the author. Two years later she was well, save for a tendency to mucous and pultaceous stools, to overcome which she decided to repeat the cure. On the journey she developed watery stools, and this state persisted for two weeks. There were four to five evacuations daily, slight meteorism, and much tenderness over the cecum and sigmoid flexure. The other organs were normal. Examination with the proctoscope showed that the sigmoid was swollen, relaxed and hyperemic, bleeding readily. No ulceration. Strong defensive contractions of the sigmoid prevented the introduction of the instrument beyond 18 cm. from the anus. Examination of feces showed good utilization of food, mucus, blood, and the absence of amebæ, dysentery, and tubercle bacilli. The diet was that prescribed by Rosenheim for severe colitis—chiefly milk and finely prepared cereals, protein being left out. Without apparent cause the disease became suddenly worse. Symptoms all aggravated, doubtless from peritonitis in the sigmoid region. Peritoneal syndrome added. Operation was refused. Further symptoms were decubitus, marantic thrombus of the left iliac vein, and severe attacks of tetany, all significant of colitis gravissima. After two months of the latter there was slow improvement. Intestinal fungi multiplied greatly, and were passed in pure culture as greenish, friable masses, causing aggarvation of symptoms. A protein diet was then installed and the carbohydrates withdrawn. As a result the proliferation of fungi ceased and patient again began to improve. She was kept under treatment until the colon was normal in every respect.

Genital Tuberculosis Cured by Röntgen Rays.—Spaeth relates the case of a young woman of sound stock who first developed pleurisy (before puberty), then chlorosis with three months of amenorrhea, and at a later period tonsillitis with protracted fever. Pirquet reaction negative. Fever assumed a hectic type, amenorrhea reappeared, intensified expiratory sound in right apex, mass in abdomen suggestive of uterine myoma, parametria infiltrated. Fearing that an abscess was forming laparotomy was performed. The tumor was as far as possible removed and tuberculosis readily recognized. The wound was left open but a second operation was soon required. More caseous matter was removed with the addition of vaginal drainage. The patient went from bad to worse, and death from exhaustion seemed impending. An application of *x*-rays, once a week, after seemingly aggravating the symptoms, gradually began to cause improvement in every direction. All evidences of local tubercle, as well as the effects of surgical intervention, and the systemic symptoms slowly disappeared. Eighteen sittings were required. The uterus and adnexa were found intact. The author gives us little idea as to the seat and genesis of the tuberculosis, but we may infer that it had ascended from the genitals to the peritoneum. He also admits that spontaneous cures of similar cases are not infrequent after laparotomy.

A Peculiar Form of Reaction of the Uterine Mucosa as a Result of Artificial Placentation of Loeb.—Antonio Gasbarrini has repeated the experiments of Loeb, in which by incisions into the uterine mucosa, at the uterine horns, an artificial decidua was caused to form, which had no connection with the contact of the ovum with the mucosa, and occurred without the necessity of fecundation. These experiments were made on rabbits and guinea pigs. Incisions were made two to nine days after ovulation. Ligation of the tubes did not prevent the reaction, but extirpation of the ovary before the experiment did prevent it. In the author's experiments the incisions were effective only after ovulation, and the reaction occurred ten days after the operation, either at the site of the incisions or at another point nearby. When incisions were not made before the period of ovulation no reaction appeared. If the ovaries had been extirpated, and an injection of fresh ovarian substance was made the reaction occurred. The author concludes that the placental reaction is caused by some active principle secreted by the ovary, which acts as a stimulant combined with the incisions.—*Annali di Ostetricia e Ginecologia.*

Book Reviews.

Klinik für psychische und nervöse Krankheiten. Herausgebeben von Robert Sommer, Dr. Med. et phil., o. Professor an der Universität Giessen. V. Band. 4 Heft Price, 3 marks. Halle a. S.: Carl Marhold Verlagsbuchhandlung, 1910.

This number contains the following essays, all written by the editor, Professor Sommer: The theory of consanguinity and insanity in man and animals; remarks on a case of inherited sexadigitism; the situation with regard to forensic psychiatry; a comparison of the German and Austrian criminal statutes, as well as of the proposals for the new statutes from the psychiatric viewpoint, psychiatry and sociology. These titles indicate the broad scope of this publication, which cannot fail to interest all students of psychiatry.

A Manual of Personal Hygiene. Proper Living Upon a Physiological Basis. By American Authors. Edited by Walter L. Pyle, A.M., M.D. Member of the American Ophthalmological Society; Fellow of the American Academy of Medicine; Fellow of the College of Physicians of Philadelphia; Ophthalmic Surgeon to Mount Sinai Hospital; Assistant Surgeon to the Wills Eye Hospital, Philadelphia, etc. Contributors: D. H. Bergey, M.D.; J. W. Courtney, M.D.; George Howard Fox, M.D.; Joel E. Goldthwait, M.D.; E. Fletcher Ingals M.D.; Walter L. Pyle, M.D.; B. Alexander Randall, M.D.; G. N. Stewart, M.D. (Edin.); Charles G. Stockton, M.D. Fourth Edition, Revised and Enlarged. Philadelphia and London: W. B. Saunders Company. 1910.

The present edition, the fourth, has been thoroughly revised and contains numerous additions. A chapter on Body-posture has been incorporated. Other new features are an illustrated System of Home-gymnastics, a chapter on Domestic Hygiene, a section on First Aid in Medical and Surgical Accidents and Emergencies, and an Appendix treating of the simpler methods of Hydrotherapy, Thermotherapy and Mechanotherapy. Although medical terms have been avoided as far as possible, for the use of the laity, a Glossary of purely technical words necessarily used in the text has been appended. The various subjects are sanely and interestingly handled. The print is of good size and the finish of the book does credit to its publishers.

International Clinics. A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles by Leading Members of the Medical Profession Throughout the World. Edited by Henry W. Cattell, A.M., M.D., Philadelphia, U. S. A. Vol. III, Twentieth Series, 1910. Philadelphia: J. B. Lippincott Company, 1910.

This has become such a well known and valuable medical periodical that only a few words need be said about the present volume. It contains over thirty articles on diagnosis, treatment, gynecology, medicine, surgery, etc. Among the titles we note The Radiation of Pain in Renal Calculus, by L. W. Gorham; Ehrlich's Diazo Reaction in Chronic Tuberculosis, by Nathan Levin; Reports of Autoserotherapy, by C. K. Austin; Some Observations on the Salt-free Diet and Chloride Metabolism, by Edward H. Goodman, etc., etc. Most of the articles are much more extensive than weekly or monthly medical journals usually print; the successive numbers of the clinics thus furnish a series of short monographs on various medical subjects. Physicians would, therefore, act wisely in becoming regular purchasers or subscribers of this Quarterly.

The Experimental Chemotherapy of Spirilloses (Syphilis, Relapsing Fever, Spirillosis of Fowls, Frambœsia). By Paul Ehrlich and S. Hata. With contributions by H. J. Nichols, New York; J. Iversen, St. Petersburg; Bitter, Cairo; and Dreyer, Cairo. Translated by A. Newbold and revised by Robert W. Felkin, M.D., F.R.S.E., etc., late Lecturer on Tropical Diseases, Edinburgh Medical School. With 34 tables in text and 5 plates. Price $4.00. New York: Rebman Company, 1123 Broadway.

The scope of this volume is amply indicated in its table of contents. Part I deals with the experimental basis of the chemotherapy of spirilla and is contributed by Ehrlich's indefatigable coworker, S. Hata. In the prolonged search for a specific remedy for diseases caused by the spirilla a large number of organic compounds were investigated. Hata speaks in detail only of those experiments which either gave positive results or which appear to be of interest from a theoretical point of view. These experiments dealt with relapsing fever, spirillosis of fowls, and syphilis of rabbits. It is noted that the spirochetes possess a whole series of chemoceptors, of which the most important are the arsenoceptor, the oxyamidoceptor, and the halogenoceptor. Part II consists of the following contributions: A preliminary report on the action of Ehrlich's substance, 606, on *Spirochæta pertenuis* (the organism causing frambesia) in the animal body, contributed by H. J. Nichols; the chemotherapy of relapsing fever, by J. Iversen of St. Petersburg; and a short report of the cases of relapsing fever treated in the Cairo Infectious Hospital, by Drs. Bitter and Dreyer. Part III consists of concluding remarks by Professor Ehrlich. In fifty pages of text the latter discusses the entire subject of chemotherapy in its theoretical and practical aspects. He describes the chemistry of salvarsan, the chemotherapy of trypanosome diseases and their consequences, and the transference of this knowledge to spirilla diseases; the technique in the practical testing of drugs; and the results and outlook. This book is recommended to those who would gain a clear insight into the brilliant experimental work that led up to the preparation of salvarsan.

The Treatment of Syphilis with Salvarsan. By Sanitätsrat Dr. Wilhelm Wechselmann of Berlin, Medical Director of the Skin and Venereal Disease Section, Rudolph Virchow Hospital, Berlin. With an introduction by Professor Dr. Paul Ehrlich of Frankfurt-on-Main, Director of the Royal Institute for Experimental Therapeutics, Frankfurt. Only authorized translation by Abraham L. Wolbarst, M.D., of New York, Consulting Genitourinary Surgeon Central Islip State Hospital, Visiting Genitourinary Surgeon People's Hospital, Professor of Genitourinary Diseases New York School of Clinical Medicine, etc. With 15 textual figures and 16 colored illustrations. Price $5.00. New York: Rebman Company; London: Rebman Limited, 1911.

In this book, as in its companion volume, a citation of its table of contents will give a fair idea of the subject-matter. In addition to the foreword by Ehrlich this consists of an introduction, Hata's experiments, the application of chemical preparations derived from animal experimentation to human pathology, consecutive treatment, *therapia sterilisans magna*, personal experiences in fourteen hundred cases, the remedy in tabes and paralysis, effect on the Wassermann reaction, complications, local and general hypersensitiveness (idiosyncrasy), necrosis, exanthemata and enanthemata, Jarisch-Herxheimer reaction, reinfection, contraindications, other effects of salvarsan, injection of the remedy, elimination of arsenic through the urine and through the intestine, retention of salvarsan in the body, review of the literature, discussion, experiences with salvarsan, summary, determination of spirochetes in patients injected with salvarsan, arsenic-fast strains not observed, *sterilisatio magna*, specific antibodies, therapy, data of recurring cases, references to the American and British literature, and list of authors. This survey of the table of contents indicates that none of the theoretical or practical aspects of the subject has been overlooked. There are sixteen colored plates illustrating the remarkable effects of Ehrlich's remedy.

An International System of Ophthalmic Practice. Edited by Walter L. Pyle, A.M., M.D., Philadelphia. Therapeutics. By Dr. A. Darier, Paris. Translated by Sydney Stephenson, M.B., F.R.C.S., London, late Honorary Secretary of the Ophthalmological Society. Illustrated. $4.00. Philadelphia: P. Blakiston's Son & Co., 1910.

The volume on therapeutics of this "System" is a book of 444 pages. The writer is an authority on the subject. The translation is by a well-known ophthalmologist and is very well done. The work is divided into two parts. Part one deals with general therapeutics. Methods of diagnosis by clinical, microscopical, bacteriological, experimental, and therapeutical means are described. Then follows a consideration of the various remedies employed and the methods of their application. Local and constitutional treatment are described, also the various forms of special therapy; as, sero-, photo-, electro-, radio-, mechanico-therapy. Part two deals with special therapeutics, taking up diseases of the various parts of the eye in logical order and considering their therapeusis separately. A comprehensive index is supplied. The author is an optimistic, enthusiastic therapeutist of wide experience. He presents the subject ably and interestingly. The text is clear, direct, and sufficiently full. The work is one of much merit and should be in the possession of all medical men who treat diseases of the eye.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON OBSTETRICS AND GYNECOLOGY.

Stated Meeting, Held February 23, 1911.

DR. H. D. FURNISS IN THE CHAIR.

Carcinoma of the Uterus: Danger of Mistakes in Diagnosis of Frozen Unstained Specimens.—Dr. HERMAN J. BOLDT presented a specimen which he had removed from a woman, forty-nine years old, married twenty-six years, the mother of seven children, the last born twelve years ago. The menopause occurred six months ago. For fourteen years she had been annoyed by something protruding from the vulva. When attending to her household duties she had bearing down pains. On examination there was found a procidentia of the second degree, the vaginal portion of the cervix having descended to the vulva. There was also a descent of the vagina and an exceptionallly large cystocele. On the posterior lip of the cervix there was a polypus; its broad base was indurated and felt quite hard, giving the impression that it was malignant. Hence before operating for the prolapsus and cystocele, the polypus was excised and a frozen section made in the laboratory. The report was returned that it was a chronic inflammatory change with nothing malignant about the specimen. An extensive operation for the descensus and cystocele was then performed. On the following day the pathologist informed him that a re-examination of the section after staining showed that he had erred in his diagnosis of a benign condition and that it was distinctly carcinomatous. The subsequent operation, because of the previous plastic operations, became technically somewhat difficult; everything that had previously been done was necessarily undone. The uterus was removed per vaginam; this was done because the disease appeared to be quite superficial; the necessity of doing an extensive operation did not seem to be present. The interesting features were the carcinomatus degeneration of a broad-based cervical polypus; the mistake in diagnosis because of an examination of an unstained frozen specimen; the entire absence of even the slightest symptoms of malignancy.

Tubal Gestation.—Dr. HERMAN J. BOLDT presented this specimen. The patient was twenty-six years old and had been married five years. She had had two abortions. For a period of two weeks she had intense cramp-like pains in the lower abdomen accompanied by atypical bleeding. There was no hematocele behind the uterus, but the adnexa on the left side were enlarged; therefore, with the history and objective symptoms a mistake in diagnosis was not likely. The only question to consider was whether the tubal abortion justified an undelayed operation or whether the patient's condition justified expectant treatment. Surgical intervention was decided upon because of the intense pain the patient obviously suffered. There was found a large quantity of fluid blood in the abdomen, but very few clots.

Fibromyoma with Hyaline and Cystic Degeneration Which Had Been Mistaken for a Malignant Tumor.—Dr. BOLDT presented this specimen. Clinically the symptoms were such that the diagnosis of a malignant neoplasm, which had been made at other hands, seemed perfectly justifiable and, indeed, was corroborated. The patient's cachectic appearance and emaciation, with the seeming immobility of the tumor, had caused other attendants to consider the condition inoperable. The pelvis was completely filled by the tumor. It was, indeed, remarkable that no pain was caused by pressure. The operation presented no difficulty.

The Present Status of the Midwife.—Dr. THOMAS DARLINGTON said that the subject assigned him involved the consideration of two phases of the question, viz., the extent to which the midwife practiced in the United States, and her fitness to discharge the duties which she assumed. It was a conservative estimate that 50 per cent. of the births in the United States were attended by midwives. In New York, during the last six years, midwives had reported over 42 per cent. of all births; in Buffalo 50 per cent. of the births were reported by midwives; in St. Louis midwives presided at 75 per cent. of the births; while in Chicago the report for one year reached as high as 86 per cent. Similar reports had been made by other cities. The midwife was commonly employed in this country by the negro and alien population, as well as by the native born of foreign parentage, and when they considered that one-third of the total population of the United States was made up of aliens and negroes they got a fair idea of the magnitude of the problem which confronted them. The midwife was an economic necessity, for she acted as visiting nurse and general adviser and frequently prepared meals and gave aid in a variety of ways which an attending physician would not attempt to offer. For both traditional and economic reasons the services of the midwife would continue to be demanded by the foreign poor and there would always be women who would respond to such calls. The practice of midwifery was by no means a local question and the reports made upon investigation by those who confronted the problem in the rural districts proved conclusively that the midwife with very few exceptions the country over, was dirty, ignorant and totally unfit to discharge the duties which she assumed. So far as Dr. Darlington had been able to ascertain the United States of America was the only civilized country in the world in which the health, as well as the life and future well-being, of mothers and infants was not safeguarded as far as possible through the training and control of midwives. In other countries this was made a national question. Everywhere in this country there was evidenced the same deplorable lack of provision for their control and for their adequate training. Excepting in a very few localities the profession of midwifery was entirely unsupervised and unrestricted, no matter how deficient the midwife might be in education, training and experience. In thirteen states there were laws purporting to require examination before licensure to practice, but extracts which the writer quoted from these laws showed how nearly useless they were as measures to regulate and control midwives in their practice. Some efforts had been made to raise the standard in New York State, but one was impressed with the dire need of further vigorous and more widespread effort. There were in this State three county laws applying to Erie, Chautauqua and Niagara counties, and two city laws applying to Rochester and New York. In New York City an old provision of the Sanitary Code of the Department of Health required midwives to register at the Board of Health. The enactment of the State Midwifery Law of June 6, 1907, empowering the city of New York to adopt rules and regulations and to make ordinances governing the practice of midwifery within its precinct was a great step in advance. It was now required that registration should be annual, that midwives should be able to read and write, be of good moral character and clean person and should have attended [illegible] cases of labor under the supervision of a licensed physician. Details of equipment and restrictive practice were also stipulated, and inspectors were [illegible] to enforce these rules. However, the present status of midwives in New York demonstrated conclusively that these measures were not sufficient to control the situation. There was no adequate provision for training, and this rendered effective enforcement of rules practically impossible. The midwives of New York City were still as a class ignorant and incompetent. They were reporting about 43

per cent. of the births annually, while it was impossible to estimate the extent of their illegitimate practice. During 1910, 975 permits to practice were issued to midwives, and it was safe to estimate that for every one registered there was one practicing who was not registered. Many of those who registered were unable to read and write. Dr. Darlington read extracts from the report of 1910 of the Research Committee of the Committee of Fourteen which showed conclusively that a large percentage of midwives investigated agreed to perform criminal abortion, and that many of them conducted sanitariums without licenses, a separate license being required for this purpose. The records in the Coroner's office in Manhattan from June 1, 1907, to March 31, 1909, showed that there were 72 deaths from abortions during that period and that 227 fetus remains were found in various parts of Manhattan and taken to the Morgue. In one so-called school of midwifery the course extended over three months, the total charge being $66, in addition to $28.50 for a book. At the end of this time a diploma was given and the recipient was allowed to register at the Board of Health and to start to practice at once. No instruments were necessary until graduation. Of ten graduates of one institution nine had been convicted of criminal practices. Dr. Darlington concluded that the midwife as she practiced to-day was a menace to the lives and health of a large percentage of the mothers and infants in the city and State of New York; that the provisions for training and control were inadequate to meet the situation; that provision for the thorough training as well as control of midwives was an urgent and imperative need; that the law empowering the Department of Health to regulate the practice of midwifery was the logical beginning, but would have to be strengthened by the establishment of schools for training; and that the medical profession should support and uphold the effort which was being made to better the practice of midwifery, which had been so degraded in the hands of women acknowledged to be for the most part dirty, ignorant and incompetent.

The Midwife in Relation to Maternal and Infant Morbidity.—Dr. Ralph W. Lobenstine read this paper. He said that this phase of the question could only be treated on the broadest lines, as figures necessarily had but a relative value. It was only the severe types of morbidity that came into the hospitals or were reported to the Board of Health. In order to deal honestly with the midwife it must be acknowledged that much that was said concerning the evil results of midwife practice here in New York could be said, even to a higher degree, of the physician. The poorly trained physician did more harm than the midwife, as was abundantly shown by the various hospital records, as well as by the records of the Board of Health. The general morbidity among infants under the care of midwives was, he believed, not especially high. They received good average care during the early days of life. This indirectly promoted the welfare of the mother, who was thus relieved of responsibility and care during the early days of the puerperium. The two points against the midwife as regarded the welfare of the child were that she was responsible for a vast amount of gonorrheal ophthalmia and its resulting blindness and that she was often responsible for the intra-partum death of the fetus. In the "Rules and Regulations Governing the Practice of Midwifery" the midwife was required to carry in her bag a 1 per cent. solution of silver nitrate with full directions as to its use, and, further, she was required to call in a physician in case of swelling of the eyelids or in the presence of a discharge. If this rule could be enforced there would be rapid decrease in the number of cases of blindness from ophthalmia neonatorum. The large number of stillbirths was due to the readiness with which the midwives undertook to manage abnormalities, to the fact that they permitted abnormally prolonged labors and to the faulty management of some of the more common conditions, as "cord around the neck," etc. The number of abortions performed each year in this city was enormous and the midwives were said to be responsible for one-third of the number. It was startling to see with what readiness they undertook this operation. This was the most serious blot on the character of the midwife. The dangers that resulted to the mother under the hands of the midwife were those that resulted from ignorance, dirt, and criminality. All three were likely to cause sepsis. The willingness of the midwife to undertake abnormalities subjected the patient to additional risks from rupture of the uterus, hemorrhage, and exhaustion from prolonged labor. Midwives had been known to undertake breech and twin deliveries; to handle adherent placenta, to tampon the uterus, and, in one instance in his series, the midwife undertook the management of an inverted uterus. Notwithstanding these gloomy facts, they had to admit that the majority of women passed through the hands of the midwife without serious damage. From a personal study of many hundreds of death reports at the New York Lying-In Hospital, as well as of a large number of histories, the midwives had been apparently responsible for about 15 per cent. of the septic morbidity. He found that in a series of 60,000 cases of obstetrics there were 208 deaths due to various types of sepsis; of this number 65 were directly traceable to the midwives. Of these 208 deaths 49 were due to criminal abortion and 11 per cent. of these were treated by midwives. By reviewing the figures of the Board of Health he found that the number of deaths from puerperal sepsis in New York City was still very large; there had been no improvement in the death rate from this cause during the past fifteen years. The Board of Health statistics corresponded closely to those of the Lying-In Hospital in showing that from one-half to one-third of the septic cases had been in the hands of midwives. Dr. Lobenstine gave statistics covering a number of years the survey of which, he said, revealed a condition of affairs that was startling and the time had come for taking active measures in regard to the midwife problem. The longer the delay in facing this problem the greater the shame upon the community.

Attempts at the Regulation of Midwife Practice.—Dr. William E. Studdiford believed that the section should express an opinion, not for the needs of any regulation of midwifery practice, but for the needs of the education of the midwives. They already had all the regulations and laws necessary for the practice of midwifery. It should be remembered that many of these women could not be properly educated. The meeting should have for its object the education of midwives, how to go about it, and what could be done. Dr. Studdiford reviewed briefly the history of the attempts at regulation of the practice of midwifery. He said that there was absolutely no place in New York City, so far as he knew, where any midwife could go to receive proper training. The Department of Health had no funds for the adequate instruction of midwives. Money was required; also a place where the midwives could go to be instructed. It was up to the medical profession to provide such places. Until they were willing to give suitable education to these midwives the physicians had none to blame but themselves for the bad and inefficient work of these midwives.

Opportunities for the Education of Midwives.—Dr. John Winters Brannan said that it was probably known to many that Bellevue Hospital was about to undertake the training of midwives. When the attention of the trustees was called to the fact that there was no place where midwives could learn to exercise their profession safely, and that it was impossible to eliminate or suppress them,

and also that the Board of Health was empowered to regulate them and required that they should know something about their profession, it seemed that the time had arrived when they should be given an opportunity to obtain some training. Therefore, the trustees decided some two months ago to establish, as soon as possible, a course of instruction for these women, and had asked the obstetricians of the hospital to state what that course should be. They appreciated that New York City had been very generous to the hospitals under their charge. Money had been freely given for the erection of new buildings. Conditions had so changed within the last five or six weeks that now they were able to say what they were going to do. The old emergency hospital was about to be vacated and could again be used for lying-in women. The upper floor would accommodate some ten or fifteen patients, and the lower floor could be fitted for lectures and demonstrations. The midwives could be lodged on the hospital grounds in one of the old dormitories. Not only a ward service but an outpatient service was contemplated. With regard to the length of the course opinions differed. On the continent it was two years; in England it was one year. Dr. Brannan felt that a short course was preferable to a long one. If they started with a short course and experience proved that a longer one was required the course could be readily lengthened, as had been done in the case of medical schools. It was up to the obstetricians to say what should be taught. The midwives should certainly receive the instruction nurses got and even more. Regarding the language, this was a difficult matter to deal with for a time; however, they should be able to find doctors and nurses who spoke sufficient German and Italian to teach at first; after a time when some midwives had been sufficiently trained they in turn might be used as teachers. Dr. Brannan suggested that they do what the Department of Health had done, have full directions printed in several languages; this would help a great deal. Recently some one had sent a midwife to Bellevue Hospital with the information that she might be taught obstetrics. From Bellevue Hospital she was sent to Harlem Hospital and taken in charge there. She was an Armenian and spoke very little English. However, she was received as a pupil and was shown how things were done in the admirable obstetric service of that hospital. At the end of four weeks, during which time she saw twenty cases, she received a certificate. This Dr. Brannan showed and thought it was of especial interest because it was the first one of the kind ever issued in this country. The Board of Health required that a midwife must see twenty cases of labor in order to obtain a license to practice. Dr. Brannan was of the opinion that when the new school was established the course of instruction should be not less than three nor more than six months in length.

The Remedy for the Midwife Problem.—Dr. J. Clifton Edgar considered this phase of the subject. He said that the time was ripe for concerted action toward the solution of the midwife problem in the United States. An anomalous condition existed; on the one hand physicians and trained nurses, before they were allowed to enter upon the practice of their professions, were required to receive instruction in the treatment and care of child-bearing women and new-born infants; while on the other hand no attempt had been made to regulate or supervise the midwives who were ignorant, untrained and incompetent women. The gist of the matter was that one of two things must be done with the midwife, she must be eliminated or else educated and placed under state control. The countries of the old world had faced and solved this problem. Most of them were familiar with the training of the German midwife, but it might not be so generally known that Holland, Belgium, France and Italy gave a full two years' training to their midwives, and that Norway, Sweden and Denmark gave one year. England, as late as 1902, had solved the problem by an Act of Parliament entitled "An Act to Secure the Better Training of Midwives and to Regulate Their Practice." Miss Crowell's graphic accounts of the character of the midwife in New York City in 1906 showed that of 500 midwives personally interviewed less than 10 per cent. could be classified as capable, reliable midwives; over 90 per cent. were hopelessly dirty, ignorant and incompetent. In order to fit midwives to practice clean and safe obstetrics they required a course of instruction, preferably prescribed by law, extending over a period of at least one year, ranking in comprehensiveness, but not as regarded time, between that given in our best educational institutions to medical students and pupil nurses, somewhat less than the former and more comprehensive than in the latter. The midwife should have thorough drill and instruction in the examination of pregnancy, including asepsis and cleanliness in its broadest sense, in the care of labor cases and of mothers and infants after confinement. There should be repeated drill in the physiology of these subjects and a clear understanding of the borderline of the pathology. In discussing the question as to how the midwives were to obtain this training, Dr. Edgar said the maternity hospitals and maternity wards of general hospitals suggested themselves, but it should be borne in mind that most of these were taxed to their utmost in caring for the instruction of medical students, pupil nurses, graduate nurses and, in some instances, affiliated nurses. The introduction of another class of pupils would lead to confusion and friction. For some years at least they would have to reckon with a class of pupil midwives less than 10 per cent. of whom could be termed capable and reliable. Many foreign midwives had but a slight knowledge of English. These objections made it appear that the solution of the problem lay in carrying this teaching into the patient's home. It was generally accepted that the medical student and the pupil nurse secured their most lasting and valuable experience in what was known as the out-door practice of obstetrics. Broadly speaking, the same method of instruction could be adapted to the needs of the pupil midwife. This solution of the educational part of the midwife problem had for its advantages over ordinary hospital ward work: 1. It was inexpensive. 2. It was the best form of instruction because it more nearly conformed with the subsequent duties of the pupil as a graduate midwife. 3. It did not disorganize existing hospital ward service. A general outline of such a plan would include the following propositions: 1. The establishment of schools for midwives in such existing out-door maternity services as should elect to do so. 2. The estab lishment of out-door maternity services in connection with existing maternity hospitals which did not already possess them, for use as schools for midwives. 3. That in each maternity service teaching midwives there should be established a school for midwives, with teachers appointed especially for the teaching of this class of pupils. 4. Rooms should be set aside for lectures, demonstrations, recitations and drilling in asepis and examination of pregnancy. Patients applying for care during confinement should be utilized for this latter purpose. 5. Time not occupied in attending cases of confinement or in lectures, etc., could be used in witnessing operation and confinements in the delivery room of the hospital proper. 6. The bulk of instruction should be given by paid instructors in the patient's own home. Eventually the more intelligent graduate midwives could be appointed as instructors in the schools for midwives. 7. Text books for the instruction and use of the midwife would naturally appear as the result of such teaching.

Dr. J. Clifton Edgar presented the following resolution, which was seconded and unanimously carried:

Whereas, It is estimated that about 50 per cent. of the births in the large cities of this country are attended by midwives (in New York City approximately 50,000 births are reported annually by midwives), and

Whereas, The profession of midwifery in this country is followed, in most instances, by ignorant, untrained, incompetent women, and

Whereas, Some of the results of obstetrical malpractice are unnecessary blindness, mental and physical degeneracy and death of infants, and unnecessary suffering, invalidism and death of mothers, and

Whereas, Although both doctors and nurses in this country are given instruction in the treatment and care of child-bearing women and new-born infants, there is no existing provision for the adequate training of women who take into their keeping the lives and future well-being of this large number of both mothers and infants, be it

Resolved, That the Section on Obstetrics and Gynecology of the New York Academy of Medicine recommend that measures be taken in this State to secure State legislation which shall provide for the training, registration, licensure, supervision, regulation and control of women engaged in the practice of midwifery.

New Instruments.

A MODIFICATION OF IVERSEN'S APPARATUS FOR THE INTRAVENOUS ADMINISTRATION OF SALVARSAN (EHRLICH).

By ABR. L. WOLBARST, M.D.,

NEW YORK.

There is still considerable diversity of opinion as to the best method of administering salvarsan (Ehrlich). The intramuscular injection of a solution, alkaline almost to the point of neutralization (Alt), has attained considerable and deserved popularity. Its use is advocated by many who are not favorably inclined to the intravenous injection. Meltzer (Medical Record, March 25, 1911) suggests that the injection should be made into the sacrospinal muscle, rather than into the gluteals. Gottheil (*International Journal of Surgery*, March, 1911) is among the most recent writers to recommend the intramuscular method. On the other hand, Ehrlich strongly recommends the intravenous method, this view being based very largely on the excellent results obtained by Iversen of St. Petersburg, Schreiber of Madgeburg, and others, who have used this method in thousands of cases with satisfactory results. Ehrlich* advises that in order to obtain the best results the intravenous injection should be given three times in six weeks—that is, two weeks apart. The ease and safety with which the intravenous injection can be given, together with the absolute absence of pain, make these repeated injections at such brief intervals possible.

Various forms of apparatus have been devised, having in view the injection of an alkaline solution of salvarsan into the venous circulation. The apparatus here described is a modification of the apparatus devised and used by Iversen of St. Petersburg, who has done brilliant pioneer work with the drug in connection with malaria, syphilis, and recurrent fever. Professor Iversen very kindly presented me with a set of the apparatus that he has used in his work, which I have modified, with his permission, to meet American methods and conditions.

*Personal communication to the writer.

The apparatus as modified consists of an Erlenmeyer flask (Josef Kavalier), having a capacity of 500 c.c., and graduated in 50 c.c. The flask is fitted with a pure rubber stopper, which is covered by a nickel plated cap. Two glass tubes, one short, the other reaching almost to the bottom, pass through the rubber stopper and metal cap into the flask. Both tubes are bent outside of the flask; one tube, the longer, is attached to a piece of rubber tubing about three feet long, the end of which is arranged to fit a glass stop-cock, to the other end of which another piece of rubber tubing, about ten inches in length, is connected. The end of this is fitted to a metal cannula, which in turn is made to fit the needle which is to be inserted into the vein. The other glass tube, the shorter, is attached to another piece of rubber tubing about two feet long, which is connected with a piece of glass tubing, expanded in the center, and filled with absorbent cotton. Its other end is fitted into a piece of rubber tubing about one foot long, to which are connected two rubber bulbs, one of these being covered with a net to prevent bursting. A metal clamp fits around the neck of the bottle, which can be projected over the rubber stopper in the manner of a

soda water bottle, so as to prevent the stopper from blowing out under pressure.

It is thus seen that the apparatus is very simple, and depends for its mechanism on an old established physical principle. The air, forced by the rubber bulbs into the bottle through the short glass tube, drives the fluid contents of the vessel before it into the long glass tube, and thence into the rubber tubing and ultimately into the vein.

Technique—The salvarsan is dissolved in a mortar and made alkaline in the customary manner, then 150 c.c. of sterile distilled water is poured into the flask, and to this is added 150 c.c. of very hot saline solution, double physiological strength; and now the alkaline solution of salvarsan in the mortar is also poured into the flask. If this solution has been made properly, the fluid in the flask should be perfectly clear, of a bright citron yellow color, and free from any particles or flakes. If, perchance, the solution is not absolutely clear, it should be filtered through sterile filter paper.

The needle having been inserted into the vein, blood is permitted to flow for a few seconds to make certain that the needle is properly placed. The rubber bulb is now squeezed a few times, and the fluid, driving all the air out of the tube before it, begins to flow through the cannula. Now while

the current is moving the cannula is inserted into the collar of the needle, and so kept in place. Meanwhile slight pressure exerted on the rubber bulb keeps up a continuous flow of the fluid, and within five or six minutes all of it has passed into the vein.

It will be observed that the current of air is filtered by passing through the glass tube filled with cotton; it is also seen that the small glass tube near the needle serves as an excellent guide to determine whether or not the fluid is passing into the vein properly. If there is any obstruction to the flow in the vein, blood will be seen in this piece of glass tubing; if, however, all is well, nothing but the clear citron colored fluid is seen. The quantity of fluid that has entered the veins is determined by the graduations on the flask, and when the full amount has been used, the needle is quickly withdrawn before there has been any opportunity for air to enter the tubing.

The fluid can be made to flow automatically by closing the stop-cock before the injection, and pumping air into the net-covered bulb up to its capacity; when all is ready for the injection, the cock is opened, and the fluid passes through the cannula into the needle automatically.

The principal advantages of this apparatus over other forms are its simplicity and economy. The most common method is to use a syringe holding 10 or 20 c.c., in conjunction with a three-way stop-cock. The fluid is drawn into the syringe through one cock, this is shut off and another is turned on and thus pumped into the vein, and so on. The possibility of getting air into the circulation by a careless manipulation of these various cocks is not a very remote one. This is also a rather expensive method. Another method is the so-called gravity method. In this apparatus there is no driving force except the hydrostatic pressure obtained by holding the vessel high up in the air. Those who use this apparatus must admit that there are times when an unduly great amount of pressure is necessary to drive the fluid into the vein, and it often happens that the pressure is insufficient, resulting in complete stasis of the fluid.

Lastly, the entire apparatus can be sterilized by boiling before each operation. The Erlenmeyer flask has been chosen solely because it is made to be boiled. The glass is very thin necessarily, but it will stand any amount of ordinary wear without breaking. The entire outfit takes up but little room, and the manufacturers have fitted up a wooden case in which the complete apparatus can be carried about readily. This makes it possible for the operation to be performed in the home of the patient without much difficulty.

105 East Nineteenth Street.

Anti-Enzyme Formation and Intoxications.—Opie, Barker, and Dochez state that an increase of anti-enzyme occurring in association with intoxication by chloroform or by phosphorus is, doubtless, similar to that which has been repeatedly observed with the cachexia of malignant growth, with various infections, and with other conditions. The increased protein disintegration which accompanies such processes is, perhaps, associated with liberation of proteolytic enzymes similar to those concerned in the post-mortem autolysis of organs. The experiments which they describe suggest that formation of anti-enzyme is a means by which the body is protected from enzymes liberated by degeneration of cells.—*Journal of Experimental Medicine.*

Medical Items.

The Value of the Uterine Sound in the Diagnosis of Cancer of the Capus Uteri.—H. Violet says that the early diagnosis of cancer of the body of the uterus cannot be obtained from the ordinary symptoms of irregular hemorrhage, serosanguinolent discharge, watery leucorrhea, etc., early enough to get the best operative results. But valuable information may be obtained by the use of the uterine sound, if it be introduced without any violence, and gently moved over the surface of the uterine mucosa. The operator feels that the enlarged end of the sound scrapes over a roughened surface that feels quite different from the normal mucosa or from placental débris, and at the same time a rasping sound may be heard as the end drags over the edge of an ulceration. In general a gentle application of the uterine sound will cause but little bleeding, but if a marked bleeding that lasts some time results it is presumptive evidence of cancerous tissue which is friable and bleeds easily.—*Lyon Médical.*

The Specific Agent of Ozena.—Paolo Barabaschi has made a study of the specific cause of ozena. He found in pure culture a coccobacillus similar to the pneumobacillus of Friedlander. The growths were easily stained with all analine colors and not decolorized by Gram stain. The organism is endowed with protoplasmic movement, but has no cilia. Intraperitoneal inoculation caused septicemia and peritonitis. The cultures had always the extremely fetid odor that is noticeable in ozena. This organism develops much like the pneumonia bacillus, but its action on milk is different, which it does not coagulate, while the bacillus of Freidlander does coagulate it rapidly.—*Giornale Internazionale delle Scienze Mediche.*

Health Reports.—The following cases of and deaths from smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended May 6, 1911.

RANDOM RECOLLECTIONS OF A LONG MEDICAL LIFE.*

By STEPHEN SMITH, A.M., M.D., LL.D.,

NEW YORK.

It would be an acknowledgment of a stage of imbecility, which I trust I have not yet reached, did I not express my appreciation of the great honor which this birthday reception confers. It is an occasion which would excite emotions of happiness, as well as gratitude, at any period of life, but to one who has so far passed the extreme limits of human longevity that but few companions of his active working days survive, such an expression of kindly and generous remembrance is peculiarly gratifying. When I take account of my associates of 1850, and speak of events of that now far off period, I may well say as did Job's messengers, "I only am escaped alone to tell thee."

But while I fully realize the honor of this occasion and am deeply impressed with the expressions of affectionate regard by those who have voiced the sentiments of its promotors, there is a deeper significance which I value more than its honor, and that is the assurance which it gives that I have an abiding place in the heart of my profession and an honorable rank in the citizenship of this city, the coming metropolis of the world.

Our birthdays always make us reminiscent, and the larger the number the more are our memories burdened with events small and great, sad and joyous, depressing and inspiring. As these returning anniversaries multiply we are more inclined to recall and dwell upon the sad and depressing, especially the loss of companion-friends, rather than upon the joyous and inspiring.

It is far more profitable, however, to review the events of the past in the light of the results which those events have effected and which we can to-day estimate at their true value. I shall not, therefore, upon this birthday dwell upon events of the past but briefly notice some of the conclusions and results which they have enforced. Of my work in several departments of human activity others have spoken in terms all too generous. I cannot let the occasion pass without adding that, for the most part, they were colaborers with me and the success that attended our joint efforts was largely due to their intelligent and judicious cooperation.

When I began the study of medicine in 1848, its principles and practice were primitive compared with the present. Diagnosis was based on observation and medicinal treatment on empiricism. As the perceptive faculties of no two persons have the same power and there was no laboratory with instruments of precision to determine doubtful questions, diagnosis was uncertain. In medication drugs were given in bulk, as organic chemistry had not analyzed and separated their constituent elements. "Shovel in the bark" was the advice in severe malaria, referring to the use of cinchona bark. The ordinary doctor carried his saddle-bags distended with bulky drugs in their crude state, the aroma of which scented the air so that his coming was known before he was visible. It was the day of the famous "shotgun" prescription, consisting of ten or more different medicines in one dose, which it was alleged was sure to kill something. We occasionally hear of the doctor of that day who, when he began practice, had ten remedies for one disease, but in more mature years had one remedy for ten diseases. The fact is that he had so much trouble in making the patient take ten different medicines that he combined them in one dose, and hence the one remedy for ten diseases, or the "shotgun" prescription.

The practice of surgery at that time seems now to have been in its infancy. Anesthetics had just been discovered, but were not in general use, and antiseptics were unknown. I saw patients operated upon without anesthesia, being held in position by strong men, and the struggles and screams of the victim, and his pathetic appeals to the operator, still linger in memory like a nightmare. In the light of that experience the great operations of former days read like miracles. It seems incredible that under such conditions Mott could have successfully placed a ligature around an artery close to the heart, or Rogers could have tied the left subclavian near its origin. The modern surgeon who operates on his unconscious patient, and, perhaps, upon a bloodless limb, is exercising little more skill than the student of the dissecting room. And in that preaseptic period the vast suppurations which followed prevented the healing of the wound of the most skilful operation, and often destroyed the life of the patient. Such a complication is now unknown. It is not too much to affirm that surgery is now so precise in its details as to be ranked as an exact science.

The first event of my student life worthy of note was an opportunity to witness the practical test of the propriety of the coeducation of the sexes in medicine. It occurred during my first course of lectures (1849) in the Geneva Medical College, Geneva, New York. The college, being in a rural district, the class was largely made up of the sons of farmers and tradesmen. A more riotous and uncivil group of young men could not well be collected. Such was their disturbance of the neighborhood that the residents in the vicinity of the college endeavored to have the school closed by injunction. Two or three weeks after the opening of the session Miss Elizabeth Blackwell, of Philadelphia, was admitted as a student, and from the moment of her entrance the class became one of the most orderly that I have ever known.

*Remarks at a dinner given to commemorate the speaker's eighty-eighth birthday, February 19, 1911.

While resident medical student of the Charity Hospital, Buffalo, 1849-50, I learned the proper treatment of Asiatic cholera, hitherto a most fatal disease. Prof. Austin Flint was the physician, and calomel and opium was his treatment. Water was strictly forbidden, though the intense thirst of the sufferers and their appeals for water were most distressing and pathetic. There was

"Water, water, everywhere,
But not a drop to drink."

The mortality was excessive. The lintel might have borne the inscription, "Who enters here leaves hope behind."

Toward the close of the epidemic a young man was admitted in an advanced stage of the disease who begged to be allowed to treat himself. All he required was a pail of cold water and a cup. Reckless, owing to our failure in treatment, I supplied him with water, warning him of the extreme danger of drinking it. He replied, "You never mind; I'll boss this job."

For a time he drank cups full of water only to deposit it with a spasm of the stomach in a farther corner of the room. After two hours and the draught of half the pail of water, his stomach quieted, the thirst subsided, the pulse became full and he slept. On the following morning he was active and well, and so boastful of his success that I had to discharge him on account of the disturbance which he created. But I had learned that the cry for water was the empty blood vessels' appeal for fluid in which the life-giving cells could circulate, the approaching stagnation of which was death.

I came to this city in 1850, via the Erie Railroad, and was landed at its New York terminal, Piermont, opposite Tarrytown. The most attractive objects in the city to a countryman then were the "Trinity Steeple," and the "Reservoir." I saw them both and felt that the half had not been told me of the height of the first, nor of the enormous proportions of the second.

The College of Physicians and Surgeons was located in Crosby street, and the most novel and interesting feature of the course of lectures was the exhibition, by Prof. Alonzo Clark, of the circulation of the blood in a frog's foot, with a single small microscope. The medical student of to-day who, with his vision increased a thousandfold, is quietly observing the very origin and development of living things, cannot even imagine the enthusiasm with which we gathered around the instrument and in turn saw for a moment the red cells flowing swiftly in the center of the stream, and the white cells loitering along the sides of the vessels.

On graduating in 1851 I entered Bellevue Hospital as interne, after a severe competitive examination with ten others for a single place. Two years in that great museum of human diseases, under the immediate instruction of Prof. Alonzo Clark, Dr. James R. Wood, Dr. John T. Metcalfe, and Dr. William H. Van Buren, was of priceless value to the student. Though we lived five together in a small room, had almshouse food, and were exposed to typhus fever from which ten of the staff suffered and two died, we regarded the advantages for clinical studies ample compensation for these discomforts and risks to life.

The social side of the hospital staff had its advantages. The members were of the better class of students of the schools, both in education and character. Friendships were formed for a lifetime. There I first met my revered friend, Professor Gouley, with whom I have since been delightfully associated in hospital work. Several of that staff became eminent as professors and practitioners, and one, Dr. John Moore, attained to the position of surgeon-general in the United States Army. The evenings at the theater where Forest and Macready appeared, and at the opera to hear Jenny Lind sing, or Ole Bull play, were full of enjoyment.

Quaint and curious incidents occur in hospital life which greatly relieve its monotony. Some were sad and some amusing. I recall the following: The warden was a testy old gentleman who had trouble with the members of the staff owing to the poor food which he served. While one of the staff was examining a pistol a cat passed his door, at which he fired. Close behind the cat was the warden, who believed the shot was intended for him. Greatly enraged, he charged the young man with attempted murder, and demanded his expulsion by the Commissioners. The culprit was brought before the Commission, the President of which was Mr. Simeon Draper, a man of infinite humor. The verdict was an admonition by the President, but not discharge, as the explanation was satisfactory as to intent. Accordingly, the doctor appeared before the Commission and the President very gravely admonished him, emphasizing the heinousness of the offense, and warning him to be on his good behavior. Then taking the doctor by the hand he whispered, "If I had my way you would be promptly discharged for being such a poor shot with such large game."

While on the staff of Bellevue I had occasion to test Professor Clark's theory that typhus fever, by his method of treatment, is most hopeful in the last, or moribund stage. The fever was at that time epidemic and the wards were crowded with cases. It was also very fatal. Ten of the staff of residents suffered attacks, and two died. At one time but two internes were able to visit the wards. When Professor Clark began his term of service he directed no other treatment than indications required until the patient was evidently in the last, or dying stage, when active medication began, the remedy employed being brandy in quantities according to its effects. In extreme cases it was given in teaspoonful doses every twenty or thirty minutes. The recoveries under this treatment far exceeded any hitherto recorded. Professor Clark was a very conservative practitioner, especially in the administration of drugs, but he had such confidence in the free use of brandy in the crisis of typhus that he once said that he regarded that stage as most hopeful and that brandy acted then like a specific.

On one of his visits he was accompanied by a professor in one of the medical schools of St. Louis, Missouri, who had heard of our success in treating typhus with brandy. He was very incredulous, and to test the treatment Professor Clark requested him to select such cases as he believed could not be saved by any treatment. He selected six, and promised to visit the hospital on the next day to see the results of treatment. These patients were all removed to a separate ward in his presence and he made full notes of each case. All of the patients were in a semi-comatose condition, and one could not be aroused. her open, glazed eyes, fallen lower jaw, lips and teeth covered with sordes, and rapid, scarcely perceptible pulse, indicating a fatal termination. But all could swallow liquids, though with difficulty. Assisted by a nurse, the brandy was given in teaspoonful doses every twenty to thirty minutes, but

the dose of the dying woman was increased to a tablespoonful every half hour. Hot milk was given with each dose.

When the St. Louis professor and Professor Clark visited the ward the next morning the patients were all conscious and able to converse with them, while their general condition indicated that the crisis was safely passed. The visiting professor was still so incredulous that he asked me privately if these were really the patients whom he had selected, intimating that some of them might have died and their places been filled by less severe cases.

At this time, also, I happened to be chosen to demonstrate that Professor Clark's new method of treating peritonitis by narcotising doses of opium would either cure or kill the patient. The maternity wards of the hospital had frequent outbreaks of this disease, and the mortality was excessive under the methods of treatment then in use. The professor believed that if the patient was so narcotised that all the functions of the body were brought as nearly as possible into a perfectly quiescent state, the inflammation of the peritoneal surfaces would subside.

His first case proved a failure owing, as he contended, to the timidity of the house physician in giving the opium. Greatly chagrined at his failure, he consulted the warden as to the member of the staff who could be relied on to carry out fully his directions. I was selected, and on conferring with the professor as to my duties, he asked, "Did you ever attend a public school?" I replied that I had. "Did the teacher ever threaten 'I will whip you to within an inch of your life?'" I answered that he had both threatened and had carried out his threat. "Then I believe you will understand what I wish you to do," he said, and added, with emphasis, "Give these patients opium to within an inch of their lives; don't be governed by the amount, but by the effect, of the opium in producing narcotism."

Five cases were soon under my care. One grain every hour for three hours without results; then two grains every hour, but no effect; next three grains, slight effect noticeable; now four grains, and I myself fell asleep from sheer exhaustion about one o'clock at night, and slept three hours. Alarmed, I ran to the ward, where I found nurse and patients all asleep. The dim light of a tallow candle on the mantel convinced me that all were safe but one, whose pallor, open eyes and fallen jaw, indicated approaching, or actual, death. Though pulseless, a slight gasp, repeated four times in a minute, proved that while "within an inch of her life," there was a possible chance of rescuing her from the second of the results of opium treatment. After two hours of artificial respiration and the use of other means she was restored from the dangers of opium, and made a complete recovery, as did three others. The fifth patient proved almost immune to the effects of opium. Her dose was increased to five grains every hour without effect, then to six, seven, eight, nine, ten, eleven, twelve, which induced simple sleep. In all she took 1,960 grains, by actual weight, of opium, or its salts, and recovered. Thus the opium treatment carried to profound narcotism changed the mortality record of puerperal peritonitis from about 75 per cent. of deaths to 100 per cent. of cures.

My first years in practice were more fruitful in valuable experiences than in money. In fact, I discovered many new remedies and methods of treating diseases which I have not made public, and which I ought, perhaps, to reveal on this occasion for the benefit of young practitioners. So, before passing to weightier matters, I will briefly mention some of my more unusual experiences and discoveries.

Outdoor life is now the popular treatment of tuberculosis. In 1853 two young Irish women, sisters, called at my clinic in the City Dispensary, one in perfect health, and the other in the last stages of consumption. The popular treatment for consumption at that time was codliver oil and whisky. Having no faith in any existing remedies in such a desperate case, it occurred to me to recommend outdoor air life, having known of the recovery of two young medical friends suffering from that disease by living out of doors in the country. I said, "If I were you, with my knowledge of the results of treatment, I would get me a peanut stand situated on the most windy street corner of Brooklyn, where they lived, and avoid living in a house." About two years afterward a buxom young woman, with a face bronzed by sun and air, came to my clinic, and smiling, said, "Why, don't you know me?" I replied "I do not recall having ever seen you before." "Don't you remember a young woman coming here two years ago so sick with consumption you thought no medicine would help and advised her to get a peanut stand on a windy Brooklyn street corner?" "I do recall the circumstance, but you are not the person." "Yes, I am," she replied. "I followed your advice and got a peanut stand, and now I am well and own a crockery store besides."

Quite accidentally I discovered a method of promptly curing erysipelas of the face and head—a very fatal disease prior to the introduction of my method of treatment. It was in the first weeks of my practice that I was called to a case in a tenement house. The patient was a girl, twelve years of age, suffering from erysipelas of the left side of her face. I prescribed the usual hospital solution, ten grains of opium and ten grains of sugar of lead. The directions were to dissolve these ingredients in a pint of water and apply the solution with a cloth to the affected parts. I explained to the mother, who seemed to be very stupid, the danger that the erysipelas would extend to the head, and thus prove fatal, unless she kept the cloths constantly applied, well saturated with the solution. Naturally, I was very anxious about the success of my treatment in a case so threatening. On visiting the patient early in the evening I found her in a profound state of coma, from which I could not arouse her. The erysipelas had extended to the head and there was no appearance of applications of the solution. It flashed upon me that the stupid mother had given the child the enormous dose, sufficient in amount to kill a dozen. On inquiry she informed me that she gave the child the "calomel and jalap powder," as she called it. I at once gave the child an emetic, which had no other effect than to add an additional poison. After three hours efforts to resuscitate the child, whose narcotism had reached a stage which indicated approaching death, I left, advising the parents that the erysipelas had spread over the head and death would soon occur. Visions of a coroner's inquest prevented sleep. In the morning I waited in an intensely anxious state of mind for the father to bring the death certificate, but he did not come. At eleven the nervous tension was so great that I ventured to go to the house, firmly resolved that if the child had died I would abandon a profession having such possibilities. On opening the door of the tenement I was confronted by my patient running and flying a paper kite. Not a trace of erysipelas was found on her face or head, her eyes

were bright, she had not only recovered from the disease, but even from the powerful poisons given her. The mother congratulated me on my success, saying she knew the girl needed the calomel and jalap badly. She recommended me to her friends as remarkably skilful in prescribing medicines, and I gained a large accession to my list of patients.

"Pluck" will save in the most desperate cases. A "tough" from the "Five Points" district entered my wards in Bellevue, having been shot, the ball entering the region of the stomach. He was in profound collapse. A consultation of surgeons decided that nothing could be done but relieve him of pain with large doses of opium, as his stomach must be damaged beyond repair. The Coroner soon arrived and began to question him as to the facts of his injury. Though scarcely able to speak, he asked the Coroner why he interfered in his affairs. The Coroner said he wished to take his ante-mortem. The patient asked "What is an anamortum?" The Coroner assured him that it was merely to aid in discovering and punishing the man who shot him. At that the patient was enraged and ordered the Coroner out of the room, saying, "Don't you touch Dick King on your life; I'll fix him when I get out so he'll do no more shooting; you keep hands off."

The opium treatment was begun and he was soon so narcotized that he was profoundly insensible. On the following day there were abundant evidences of general peritonitis, but whenever he became conscious he muttered vengeance against his antagonist and the Coroner, always asserting that he would recover. On the third day there was a slight improvement of the symptoms, and on the fourth day they had so far abated as to make it certain that he would recover. He left the hospital fully recovered in about a month. Several months later, on visiting the hospital, I saw a rough-looking man standing on the opposite side of the street who called out, "Hello, Doc, don't you know me?" I said, "No." "Why, don't you remember the feller in your ward who was shot in the stomach?" he asked. "Yes," I replied, "but you are not the man." "Yes, I am," he said, "and I want to tell you that Dick King'll never shoot any one again, and I'm on the track of that feller who wanted anamortum so badly. I'd like a shot at him for butting into my business." I asked, "What has become of that ball?" Passing his hand over the stomach, he replied, "Oh, I suppose it is rolling around here somewhere, for I have gripes sometimes just as I had as a boy when I ate green apples." The lesson which I learned from that case was never to discourage a patient by word, act or suggestion, however desperate the conditions might be.

"Meddlesome midwifery is bad" was an aphorism so often stated in the books and so frequently quoted by professors in the colleges that I began practice profoundly impressed with its importance. I early had an opportunity to demonstrate its truth. My patient was a stalwart Irish woman, mother of six children, living in a shanty on a vacant lot where Altman built his first store, corner Sixth avenue and Nineteenth street. On leaving her I gave minute directions as to her care. She must lie in bed nine days; take simple, liquid food; and have no company. I returned home with a conscious pride of having strictly complied with the directions of the books. On visiting my patient on the following morning I was surprised as I stood at the door to hear the sound of dancing and the shrill voice of a woman singing Moore's song,

"The harp that once through Tara's Halls
The soul of music shed."

I gently opened the door and was astounded to discover that the dancer and singer was my patient, and that three of her neighbors made up the audience. I learned that she had prepared her husband's breakfast, ate with him, and was now entertaining her neighbors. I remonstrated at her imprudence, and declared that I would not be responsible for the results of such a violation of the rules governing her convalescence, to which she replied, "Oh, get out, boy; I guess I know more about this business than you do." Shouts of laughter greeted her remark, in the midst of which I retired, satisfied that "meddlesome midwifery is bad."

My public life, to which allusion has been made, began in a rock-ribbed Jacksonian town in a remote district of Onondaga County where I became a candidate for a minor office on the "Liberty Party" ticket. I received two votes, one was cast by the friend who nominated me, and the other by myself. I soon after left the farm and the town and the recent appeals, "Back to the farm," awakens no responsive feeling.

In regard to my work in various fields alluded to by previous speakers I will only refer to some of the conclusions which I have formed from my experience in these several departments.

My "Ancient Friend," as he subscribes himself, Professor Gouley, with whom I have been intimately associated in hospital work now three score years, recalls our teaching and practice of surgery in Bellevue. As a student and teacher I was early impressed with Bacon's maxim, "He that questioneth much learneth much." Therefore, in teaching I adopted the system of class recitations in which teacher and pupil are brought into such personal relations that they mutually question each other. With touch of elbows they study together in the dissecting room, in the laboratory, and in the hospital wards. Never before in this country had the hospital been brought into immediate relations with the school. Like all inovations, the Bellevue clinics were ridiculed and made the subject of cartoons, but practising physicians everywhere recognized their value and the classes in attendance rapidly increased in numbers. Practically along that line Bellevue has developed into a great center of medical education. The ancient professor in evening dress, with well-conned manuscript in hand, and eyes adorned with gold-rimmed glasses, is being relegated to the scrap heap of medieval curiosities.

I will add that the full value of the hospital in medical education has not yet been secured. It ought to be a condition of graduation from a medical college of this city that the candidate has had at least one year's service in a hospital as an ordinary ward attendant. It would not be difficult to supply the public, and even some private hospitals, with medical students, both as members of the resident staffs and as ward attendants, greatly to the benefit of both parties. The hospital could secure the services of a far higher grade of attendants, and the student would gain that personal contact and care of the sick which years of private practice would not yield.

My experience in teaching anatomy led me to adopt the method of Paley, or the synthetic method. The pupil becomes an inventor and mechanic. He studies design, cause and effect, function and its mechanism. From the first he is creating a machine to meet a given want and throughout the course he

is constantly endeavoring to devise and adapt means to an end. This method of studying anatomy awakens in the student's mind the intense interest of the inventor, the mechanic, the creator.

My editorial work alluded to by Dr. Jacobi was on a new weekly medical periodical, the *American Medical Times*. The special feature of that periodical was a leading editorial in each number devoted to critical comments on current events of a medico-public character. The object sought to be accomplished by a free-hand discussion in these editorials of topics of common conversation and interest was to draw lessons from the social, business, and political life of the community which would tend to elevate the standard of medical ethics, promote professional morality and respectability, and establish right relations between the medical art and the Municipality, State, and Nation, in the conservation of the public health. The field of medical journalism upon which the new weekly entered has been altogether neglected in this country.

Prof. Chandler has graphically described the work of the Board of Health of New York during his presidency and while I was associated with him as a Commissioner, 1873-75. I had been active in securing the enactment of the Metropolitan Health Law in 1866 and was a member of the Board, 1868-1875. Important as was the work of the Metropolitan Board of Health during the four years of its existence it was so dominated by the Tweed régime finally that the law was not allowed to have its full force. It was not until the reform administration of Mayor Havemeyer came into power, in 1873, that its autocratic powers were fully asserted. The board was now reduced from eight to four members, and Professor Chandler was appointed president. Then began the militant career of the board against nuisances "dangerous to life and detrimental to health" which were hoary with age and safeguarded by corporate wealth and political influence. The full import and value of the metropolitan law was now made apparent, not only to the citizens of New York, but to the entire country. As a result, boards of health sprang up in the leading cities of the United States, based on this law, and to-day it may be said that it is the foundation on which rests our municipal, State and National system of sanitary administration.

As a member of the National Board of Health (1870-84) I formed positive opinions as to the method of securing a National Department of Health, a subject now in an acute stage of popular agitation. The widespread epidemic of yellow fever in 1878-79 created a strong sentiment in the Southern States favorable to the creation of a central health authority which could bring to the aid of local, State, and municipal health boards the power and resources of the general government. Heretofore the fear that "States' rights" might be invaded by such an organization had prevented any attempt to secure legislation by Congress to that end, but the entire inability of the health authorities of the States to cope with the epidemic of 1878 and the fear of its return in 1879 completely overcame all opposition, and there was a popular demand that some form of central organization should be perfected by which the aid of the government could be secured in case of an outbreak in the following year.

Several bills were submitted to Congress, and of these I prepared one which was presented to the Senate by Senator Lamar. It was drawn along the lines of the act creating an Agricultural Department, and provided a Secretary of Health who was to be a member of the Cabinet. In the discussions which followed over these several measures it became apparent that it would be only by a slow evolution from some simple beginning that finally a Secretary of Health would be secured and that the passage of the bill which I had prepared must be the culmination of years of experience. In the Marine Hospital service, then under Surgeon-General Woodworth, an able sanitarian, I recognized an organization in the government already performing duties in connection with quarantine which might, by successive additions to its powers and duties, be gradually advanced to the position which my bill contemplated, viz., a Department of Public Health with its Secretary having a seat in the Cabinet. The progress of events has verified my prediction; the scope of public health duties of the Marine Hospital service have from time to time been largely increased; its name has assumed the additional title "Public Health," and to-day it is performing in an admirable manner the larger and more important functions of a Department. In the natural order of evolution the next advance will be in the direction of a more or less complete installation of that Service as the Department of Health.

The final act of my service in the field of public health was an appointment by President Cleveland as delegate from the United States to the "Ninth International Sanitary Conference," held in Paris, in 1894. The subject matter of that conference was the formulation of a code of rules and regulations governing the sanitary conditions under which pilgrimages from Asia and Europe are made to Mecca. It was contended by the French government that cholera was always brought to Europe by pilgrims from districts in Asia where the disease prevailed, especially from the valley of the Ganges, who communicated it to pilgrims from Europe, in Mecca. The custom of the pilgrims was to visit Mecca when sick; to carry large quantities of filthy baggage; to bathe in sacred pools and drink the foul water. Sixty-two per cent. of these pilgrims never return, but die *en route*.

It was believed that if an international code of rules governing these pilgrimages could be enforced cholera would never reach Europe. The Conference consisted of three delegates from each of the powers of Europe and Asia, and the United States. It made 400 pages (folio) of rules, which dealt with every stage of progress of the pilgrim, from his home to, and while at, Mecca, and return. He must be in good health; have means to pay all his expenses; must carry only washable clothes in a grip-sack; bathe daily for a week before leaving; carry a sanitary card certifying compliance with every rule; embark only on a "pilgrim ship" made expressly for pilgrims; stop for a week at designated stations, and bathe daily and have all of his clothes washed; report to the sanitary officer at Mecca and remain under his supervision.

The English and Turkish delegates, on whose governments compliance chiefly rested, opposed the rules as impracticable, owing to the religious prejudices of the pilgrims, but they were approved by a large majority. The Conference also created a commission to remain permanently at Constantinople to supervise the enforcement of the rules.

My work and experience in the Prison Association, as commissioner of the State Board of Charities, and State Commissioner in Lunacy, alluded to by Hon. William R. Stewart, president of the State

Board of Charities, and by Dr. Carlos F. McDonald, formerly president of the State Commission in Lunacy, included the study and treatment of the criminal, insane, feebleminded, destitute, defective and pauper classes. The net result of my studies is the firm belief that the policy of the State in their care and treatment should be radically changed and placed on the basis of the following teachings of modern physiology and psychology:

The human brain is not a homogeneous mass, but a mechanism, endowed with faculties which depend upon the structural arrangement of its ultimate elements. These elements consist of minute bodies known as cells. It is estimated there are thousands of millions of these cells. Every nerve cell has its own special function, and these functions are as numerous as the acts and even the thoughts of the individual. Every vital function, as well as every mental operation, thought and act, has its origin and expression in one or many of these entities or units of the nervous system. Therefore, the personality of every individual depends upon the condition of these cells.

When acting under their proper stimulants these cells increase in size because of the increased blood supply, and when this stimulation is withdrawn the cells atrophy, or waste, and become inert. Hence we have it in our power to stimulate any part of the brain to activity if we know its special stimulant, or by withdrawing that stimulant to reduce the cells to their rudimentary state. In other words, we have the power of increasing, diminishing, and even reducing to quiescence, any portion of the brain to which we apply or withhold the proper stimulants. The most immediate and powerful agents in effecting these cell changes are nutrition, pure air, exercise. The special stimulants are exceedingly numerous, being found in the food we eat, the fluids we drink, the sights we see, the sounds we hear, the things we touch, the taste and smell.

With this knowledge of our power over the functions of the brain cells, the agents of all mental processes, that is, our ability to increase or diminish their activity at our will, I would construct a State policy in regard to the care and treatment of the several dependent classes as follows:

1. The idiots and feeble-minded, whose brain cells are feeble in structure and have not been at all or only imperfectly developed, should be placed in institutions equipped to awaken these dormant elements, and develop their functions along lines of self-care and self-support. This was the practice of Howe and Wilbur.

2. The criminals, whose brain cells inciting to vice and crime have been made extremely active by heredity, indulgence in vicious practices, or disease, should be placed and retained until reformed, in training schools provided with adequate means of removing every incentive to vice and substituting every incentive to virtue, combined with suitable food, pure air and instructive and diverting employment. These conditions are found, not in prison structures, but in the cultivation of farm lands. Many European nations are adopting the policy of removing criminals from prisons and locating them on large tracts of land, with most favorable results, both as to economy of maintenance and the reform of the prisoners.

3. The insane who are suffering from disturbances, or actual destruction, of one or more nerve centers, should be placed under conditions where the former class would be cured and the latter made useful. Nearly one-half of the inmates of asylums is estimated to be suffering only from disturbance, and not from disease of the nerve centers. This first class would be cured if the individuals were placed under skilled treatment in institutions provided for the segregation of each individual from other insane and the employment of every means necessary for the removal of the cause of disturbance and the promotion of health by education, industry, and diversion.

The second class should be made useful by colonizing them on large areas of farm lands in family cottages, and provided with diversified industries. This was the view of Dr. Brigham. Would it not be possible under such a system to cure even 100 per cent. of the first class of the insane admitted to our hospitals, and could not the second class be made self supporting?

4. The pauper class should be colonized on farm lands, in family cottages, and every one physically able to do any kind of work should be compelled to be employed, and thus make the colony, as far as possible, self supporting. This scheme has proved successful abroad.

The remarks of President Stewart, with whom I have been intimately associated in charitable work for upwards of a generation, lead me to the following conclusions in regard to the State policy of supervising its public charities.

It is a fundamental principle in our form of government that the people should be familiar with, and as far as possible participate in, the management and control of public institutions. The organization of the State Board of Charities and the State charitable institutions under its supervision, meets that condition as far as practicable. In the first place, every such institution has its board of managers of men and women, selected by the Governor and the Senate, who serve without remuneration. This plan secures the active interest of a body of the most prominent citizens of the State in the management of that single institution. Second, the State Board of Charities, constituted of one member from each of nine judicial districts, and three from New York City, appointed by the Governor and the Senate, and serving without pay, exercises a visitorial and advisory jurisdiction over all of its affairs. This system of administration of all of the State charitable, eleemosynary, prison, and reformatory institutions, has always given the best economical and practical results.

My reverend friend, Dr. MacArthur, has spoken in very flattering terms of the "Physician as Citizen," and illustrated his subject by reference to my discharge of official duties. Had he known how I terminated my career as a public functionary he would have selected some other person as his ideal. It happened in this wise:

During the closing months of Mayor Strong's reform administration I was appointed by him president of the Department of Charities of this city. Having been familiar with the management of its affairs for forty years and having personal knowledge of its defects, I had very positive opinions of the reforms needed, and at once began to plan operations. While engaged in correcting minor defects in detail, the great reform which I hoped to initiate was the removal of the 10,000 or more dependents from the immense prison-like island structures and colonize them on farm lands in the country. From long acquaintance with these people I was satisfied that a large percentage of the men and

women whom the city is supporting in idleness could earn their livelihood if they were housed in very simple family cottages and were required to do the diversified work of the ordinary farm. Besides, they would be infinitely happier and healthier in these unpretentious homes constantly occupied in outdoor work than they are while incarcerated in the repulsive, unsanitary buildings on the island. But as I was about to put my projected reforms into effect they were brought to an untimely end by the new Mayor, Mr. Van Wyck, who, on assuming office on the first of January, served me with the following polite official note:

"Sir—You are hereby removed from office for the good of the service."

What the failure of my plans has cost New York can be only roughly estimated. Several millions of dollars have since been expended in repairing old and in erecting new buildings, and the latest estimate of the money now required to complete projected improvements is $12,000,000. Meantime, the idle population is increasing and not a dollar of revenue is returned to the city. If one-sixth of the $12,000,000 had been judiciously expended in colonizing these people the city would be relieved of an ever-increasing burden of taxation, and this vast population would be placed in homes and at occupations better adapted for their comfort and health.

Perhaps I ought to mention an incident in my public career in which I quite innocently received the honors paid to a Baron and temporarily enjoyed the distinction which that title gives at a foreign Court. As a delegate from the government of the United States to the International Sanitary Conference of Paris I was invited to the first of the two grand receptions which the President annually gives, and which are the great social events of the season. On entering the immense reception room of the Elysian Palace, where the President and Madame Carnot, and a large body of distinguished citizens were receiving, the usher did not get my name and asked me to repeat it. I replied, giving emphasis to the first name, whereupon he announced with a loud voice, "Baron Stien."

On approaching the President he advanced two or three steps, and shaking hands cordially, presented me to Madame Carnot, and I passed down the long line, being greeted by the men with formal bows, and by the ladies with the waving of handkerchiefs. Mr. Hayne, dean of the corps of reporters, to whom I had letters of introduction, met me with congratulations on the great honor which I had received, assuring me that the President never steps out of line except on the reception of a Prince or a Baron. Wherever I went in the crowd that evening every one stepped aside and bowed, and I heard frequent whispered inquiries, "Who is this Baron Stien?"

I cannot bring this delightful birthday to a close without again expressing my appreciation of the personal esteem which prompted it, and the all too complimentary remarks of the friends who have spoken. But undoubtedly there is this underlying and unspoken sentiment in your minds, "Pity the sorrows of the poor old man."

But I can assure you that old age has its amenities and compensations. At the age of eighty we are no longer strap-hangers in the crowded car. And it is interesting, and sometimes amusing, as we enter the car to see a gray haired man or woman—rarely a young man—arise and beckon us to a seat. And then there is that freedom from constraint and conventionality in habits, dress and manners which give a peculiar zest to life, as all these defects are readily attributed to age. No one criticizes our unpolished shoes, nor our displaced neckwear, nor even counts the number of hairs on our coat collars, but life runs smoothly on to its close.

Looking backward through the long vista of fourscore and eight years, and summarizing its events and experiences, two lessons are forcibly impressed upon my mind. The first is that the greater and more important results have followed the common and apparently least important events; and the second is that I have had little or nothing to do in planning or shaping the life which I have actually lived. The application of these lessons is, as to the first, according to Pliny:

"Let not things, because they are common, enjoy for that the less share of our consideration."

As to the second lesson, Shakespeare teaches that:

"There's a divinity that shapes our ends,
Rough-hew them how we will."

Hippocrates thus admonished the students of Cos: "Life is short, art is long, the occasion fleeting." No one so fully realizes the truth and beauty of these terse aphorisms as one who has passed into his ninth decade. Life to him is but a half-remembered dream; art has been an ever-increasing pressure upon his energies; occasions improved or lost are joyous or sad memories.

The art of prolonging life has been the study of the ages, and innumerable are the methods proposed. But no one plan of living, no one medicinal agent, has been discovered that insures perpetual youth. Heredity and the simple life give the best results. But there comes a time to every one, "whether soon or late," as Whittier wrote, when the fires of passion and ambition have burned out, the pulse slows down, the vital currents flow more and more sluggishly in their courses, and all the forces of nature tend to quietude, repose, rest. Happy the man whose life, whether short or long, is filled with honest efforts to cultivate every art that benefits mankind, and has seized every occasion to apply it where and when it was most needful and useful in uplifting the race. Then, "Or ever the Silver Cord be loosed, or the Golden Bowl be broken," he may, by Grace, pass, with these last words of Sir Henry Irving on his lips,

"INTO THY HANDS, O LORD."

UTERINE CANCER AND ITS EARLY DIAGNOSIS.

ORIGINAL RESEARCH FROM SUBJECTIVE SYMPTOMS.

By E. ATLEE, M.D.,

PHILADELPHIA, PA.

All clinicians realize the importance of obtaining the earliest possible knowledge, from subjective symptoms, of cancer formation. The following research is a contribution to a significant phenomenon.

It is a recognized fact that the victims of uterine cancer are frequently women of excessive avoirdupois, but the scientific physician has not as yet taken into consideration the possibility that the feature of *weight* may be a help in connection with an early diagnosis of the disease; nor that it may prove to be an important help in differential diagnosis.

The surgeon frequently sees women who, in the first recognized stages of cancer of the uterus, give no history of loss of flesh, and yet these same women may differ greatly in their respective weights

at this identical early stage of the disease. Weights of from 125 to 250 pounds, more or less, are met with. With such numerical discrepancies it is no wonder that the significance of avoirdupois has been overlooked by those diligently searching for some pathognomonic prephenomenon of uterine cancer. The point of importance to be considered is, not *actual* weight of the individual, but *comparative* weight of that individual at different periods. The actual maximum weight of the constitutionally light woman can but differ greatly from the actual maximum weight of the constitutionally heavy woman.

In the furtherance of this research, twenty-four cases have been carefully studied, and the testimony points almost conclusively one way, viz., that the *incipient* stage of cancer of the uterus is coincident with the *maximum weight* of the woman, irrespective of age; and that the duration of this incipient stage may vary, as does that of the recognized stage of the disease.

The cases included in Table I give definite answers to the following four questions: (1) Present age? (2) About how long ago was maximum weight attained? (3) About how long did maximum weight continue? (4) About how long ago did pain, hemorrhage, or discharge appear?

TABLE I.

(Every Case Diagnosed Inoperable Cancer of the Uterus by a Competent Surgeon.)

Case	Age.	Maximum Weight Attained About	Duration of Maximum Weight, Good Health and Strength About	Symptoms Appeared
1	52	5 yrs. age	4 yrs.	7 mo. age
2	58	3 " "	1 or 2 "	5 " "
3	38	7 " "	5 "	2 yrs. 3 " "
4	54	4 " "	3 "	10 " "
5	66	10 " "	6 "	5 " "

The next cases, also pronounced cancer by prominent surgeons, gave decided history of recent maximum weight, but time of its attainment was not definitely stated, or all questions were not answered.

TABLE II.

Case	Age.	
1	46	Weighed the most the last couple of years.
2	50	Two years ago weighed 214, weighed as much she thought for some time before
3	37	Fall previous to first hemorrhage, weight was about 145; never weighed as much before.
4	58	This fall weighed 145; did not remember weighing more; used to generally weigh about 126.
5	48	She weighed the most she ever weighed, or 125, just before she started to be sick.
6	36	Weighs the least now. Two years ago weighed 169. When 16, weighed 136. Began to get gradually thinner 8 months ago after baby was born.
7	37	Was stoutest 3 or 4 months before the bleeding
8	71	Weighed more than she ever did about 5 years ago.
9	53	Was stoutest the last few years before she was taken sick. (Menopause 13 years ago.)
10	52	Thinks she was stoutest about 3 years ago
11	58	(About). Attained greatest weight about 5 years ago.
12	62	Weighed the most she ever weighed, or 156, before the bleeding.
13	68	Very stout a year ago; never stouter than 4 or 5 years ago.

Of the remaining six out of the twenty-four women interviewed, some could "not remember" or had "never been weighed." Only one gave a positive history of maximum weight many years ago.

The third table is compiled from data contributed by prominent surgeons and gathered in most part from cases at the time in the hospitals, in order to test whether or no my questioning had been leading.

The existence of maximum weight would not alone be sufficient to determine the presence of uterine cancer. Associated with the history of maximum weight in the incipient stage of cancer of the uterus will be found one of unexcelled health and strength; but this maximum weight, health, and strength will have been *rapidly* attained, subsequent to *previous imperfect health conditions* (in some cases slight). Concurrent with these features of suddenly acquired perfect health will shortly appear an increasing mental and physical apathy, together with a rather abnormal inclination to sleep.

TABLE III.

Case	Age.	
1	48	Maximum weight 2 years before symptoms appeared.
2	45	" " 1 " " " "
3	50	" " 2 " " " "
4	40	" " 6 months " " "
5	38	" " about time of appearance of symptoms.

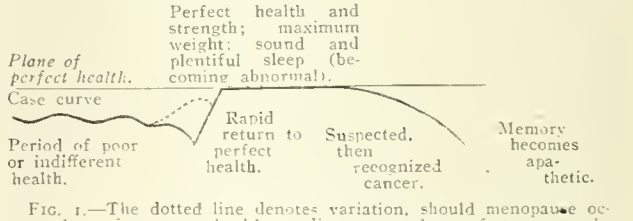
(NOTE:—The above tables include *every* case interviewed.)

The following chart gives what I believe to be the probable characteristic phenomenon in the progress of uterine cancer cases, and covers possibly a period of twelve years or more.



Perfect health and strength; maximum weight; sound and plentiful sleep (becoming abnormal).
Plane of perfect health.
Case curve
Period of poor or indifferent health.
Rapid return to perfect health.
Suspected, then recognized cancer.
Memory becomes apathetic.

FIG. 1.—The dotted line denotes variation, should menopause occur. In a few cases, health conditions may be perfect, or nearly so (*i.e.* the case curve may coincide with the plane of perfect health), until a very short time before the *rapid return to perfect health.*

Controls for the above weight (or health) curve of uterine cancer are found in: (1) Weight (or health) curve in uterine diseases other than cancer. (2) Weight (or health) curve in cancerous diseases other than of the uterus (women). (3) Weight curve in normal women.

Groups 1 and 2 will show a varying weight (or health) curve which nowhere coincides with the plane of perfect health within "possibly a period of twelve years or more" previous to diagnosis. The following chart illustrates such a curve.

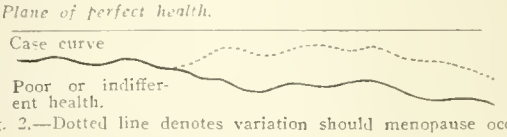


Fig. 2.—Dotted line denotes variation should menopause occur.

The demur is raised that woman naturally attains her maximum weight at an age (after menopause) when she is most apt to become the victim of uterine cancer. Looking up the statistics of a life insurance company, I find the average weights of women between certain ages shown in Table VI, Group III, p. 899.

TABLE IV.—CONTROL GROUP I.
(Uterine Diseases Other Than Cancer.)

Case.	Age.	
1	40	Adenomyoma posterior uterine wall. Never strong.
2	43	Interstitial uterine myomata. For 28 years health has been poor.
3	35	Adenomyoma of the uterus. Always rather delicate
4	33	Diffuse adenomyomata. Chronic invalid for years
5	51	Myomata Patient has always been a frail woman The above 5 cases taken from Dr T S Cullen's "Adenomyoma of the Uterus," show unmistakable variation from normal, of health curve in list "12 years."
6	47	Ulceration of cervix. Wretched health for 7 years
7	37	Fibroid uterus. Always poor health. Maximum weight 17 years ago.
8	39	Uterine polypus. Metrorrhagia and weakness for years.
9	63	Hypertrophic endometritis. Not well for six years.
10	35	Uterine fibroid. Very poor health for years.
11	52	Uterine fibroid. Indigestion and nervousness for many years.
12	39	Fibroid endometritis. Maximum weight 11 years ago
13	29	Endometritis. Maximum weight 5 years ago
14	26	Tuberculosis of the endometrium. Patient has always been rather frail.
15	33	Tuberculosis of the endometrium. Not strong since pelvic inflammation 12 years ago.
16	40	Adenomyoma uteri diffusum benignum. The patient has never been strong.

TABLE V.—CONTROL GROUP II.
(Cancerous Diseases Other Than of the Uterus

Case	Age.	
1	69	Epithelioma of the nose. Some spinal deformity [illegible] age. (?)
2	44	Carcinoma of breast. Maximum weight 20 years ago
3	63	Epithelioma of skin of hand. Always thin, ever since she can remember.
4	33	Carcinoma of urethra Slender and somewhat delicate, has lost 35 pounds in 4 or 5 years.
5	58	Carcinoma of breast. Maximum weight 14 or 15 years ago.
6	36	Carcinoma of tongue. Formerly suffered from intestinal indigestion, and considerable abdominal pain
7	80	Cancer of right breast. Never strong. Maximum weight 40 years ago.
8	54	Carcinoma of right breast. Indigestion for 10 years.
9	60	Carcinoma of left breast. Maximum weight 10 years ago
10	44	Carcinoma of breast. Maximum weight 25 years ago. Always delicate.
11	85	Epithelioma of upper lip. Maximum weight 60 years ago.
12	69	Epithelioma of upper lip, and carcinoma of right breast. Maximum weight 10 years ago.
13	62	Epithelioma of upper lip. Demented
14	57	Carcinoma of right breast. Womb trouble for 18 years
15	49	Carcinoma of the vulva. Maximum weight in recent years. Always more or less nervous
16	69	Carcinoma of rectum. Has not been a strong woman.
17	50	Carcinoma of right breast. Indigestion for many years
18	60	Gastric cancer. Health began to fail 10 years ago Maximum weight 20 years ago.
19	47	Cancer of stomach. Pretty stout 1 year ago; but a little stouter about 10 years ago. Pelvic treatment and supports on and off for years.

TABLE VI.—GROUP III.
(Weight Curve in Normal Women.)

15 to 19 years of age	122 pounds
20 " 24 " " "	126 "
25 " 29 " " "	128 "
30 " 34 " " "	132 "
35 " 39 " " "	136 "
40 " 44 " " "	138 "
45 " 49 " " "	142
50 " 54 " " "	144
55 " 59 " " "	145
60 " 64 " " "	143

If the average normal woman attains her maximum weight between the ages of 55 and 59, it must be considered probable that out of the thirty-nine cases of uterine cancer quoted above, but twelve of the women could have been suffering with the disease in any of its stages (assumed maximum duration of the disease, ten plus two, or twelve, years) at an age when the average normal woman attains her maximum weight.

The accompanying figures relate to the date of onset of the first symptoms of cancer of the cervix uteri, and were compiled from 500 cases by Dr. W. Roger Williams. If one compares these figures with ages at which an average maximum weight is attained by normal woman (as per above data), there seem to be considerable diversities.

Age Periods	Cervix Uteri. Per Cent.
20 to 25	0.2
25 " 30	7.0
30 " 35	11.0

60 " 65	5.0
65 " 70	1.0
Over 70	0.8

Differential Diagnosis.—A woman of 45 had been admitted to the carcinoma ward (D. O. W.) of a large general hospital. When I first saw her a curettage had already been done, but the microscopic examination had not yet been made. Exhaustive notes were taken of the case, but no history of recent maximum weight, excellent health, or strength could be found; the woman told a story of ill-health of long standing, without any period of perfect relief. The consequent negative diagnosis was later corroborated by the pathologist.

Organic disorders, and some external influences, such as the abuse of patent medicines, etc., may interfere in a few cases with a clear diagnosis of uterine cancer; for example: A woman of 51 years of age gave a history of recent unexcelled health and strength, but not of maximum weight. I learned that some months previous she had passed a tapeworm five yards long.

Women will be met with who present a history of maximum weight not concurrent with perfect health and strength. The maximum weight in such cases will not represent the highest possible weight attainable either in perfect health or in the incipient stage of uterine cancer.

In taking histories, note the distinction between *perfect health* and *so-called normal* health. Women who have had functional disorders will frequently state that they have had *perfect health*, but will contradict such statement when asked whether they ever took medicine or consulted a physician.

THE PROGNOSIS OF LOBAR PNEUMONIA.

By THOMAS F. REILLY, M.D.,

NEW YORK.

PROFESSOR OF APPLIED THERAPEUTICS, MEDICAL DEPARTMENT, FORDHAM UNIVERSITY.

THE prognosis of any serious disease is by far the most uncertain problem the clinician must face. "Art is long and experience fallacious," said the father of medicine, and this is eminently true of pneumonia. Any statements made dogmatically in the course of this paper are subject to exceptions. Every one has seen cases of this disease that apparently were doomed to die, but that, instead, recovered, and the reverse. We have no scientific apparatus by means of which we can measure the prognosis in any case. This must rest entirely on the likelihood of the case following the same course as similar cases have done. The doctrine of chances in medicine nowhere holds its place so strongly as in prognosis. It is only by grouping together certain types of each disease that occur under similar surroundings that any reasonable foundation for prognosis in any case can be laid. These data are so variable that this classification is very often well-nigh impossible. It shall be my aim rather to bring together the important symptom groups as they are associated with the age and condition of the patient's organs. In general, the prognosis of lobar pneu-

monia depends on the character of the soil and the virulence of the infection. In addition, there is the added consideration that a vital organ is involved.

In this disease, with the exception of epidemic pneumonia, the character of the soil is the most important factor. The character of the soil involves a consideration of the age, habits, family history, condition of the heart, kidneys, and, lastly, of the treatment. The general mortality rate in hospital practice is about 22 per cent. In private practice it varies from 8 to 12 per cent. The age statistics, as one finds them in hospital practice, are so full of complicating factors that it is impossible to arrive at any satisfactory conclusion, except to say that in the first six months of life the mortality rate is very high, possibly 30 per cent., and in the period over 45 the mortality rate gradually rises up to 90 per cent. As a general rule proposition, one may say that frank, uncomplicated lobar pneumonia in a healthy adult under 50 years of age, not involving more than one lobe at a time, will eventuate in recovery. Here again one must except pneumonia of the epidemic type. The course of the disease varies so much at the extremes of life that one must predicate an entirely different set of principles to govern our judgment at these ages from those upon which we base an opinion in adults. In children under six months of age the mortality rate is about 30 per cent.; after the age of one year, pneumonia is a benign disease. In private practice, in this climate, the mortality rate up to 15 years will not average more than 3 per cent. The factors on which one bases a prognosis in children, while similar in many respects to those by which we arrive at a conclusion in the case of adults, differ materially in many particulars. In 70 per cent. of the cases the decline is by lysis. The mortality is lowest when the temperature does not go over 103°. A low temperature in a child is always a good sign. It is not always so in adults or the aged. The mortality rate is highest when it is over 106° F. Between these two extremes there is no difference as far as the mortality rate is concerned. It is rare for a child to die whose pulse has not been persistently above 130 per minute. Few cases die with a respiration rate below 35 to the minute.

Otitis media is the commonest complication in some years, occurring in 18 per cent. of these cases. Empyema is the next in order of frequency. It is present in more than 5 per cent. of the cases. These complications, provided they are recognized early and treated on modern surgical principles, do not materially affect the mortality. When this is not done, it is impossible to estimate their relative dangers. The otitis cases generally represent a severe type of the disease, although not nearly as virulent as similar cases in adults. Pericarditis is a fatal complication. Meningitis, when it occurs, is usually associated with endocarditis. It occurs in 8 per cent. of fatal cases. The mortality is nearly 96 per cent. Among the good signs may be mentioned the regularity of the appearance and moderation of the symptoms and course, and the absence of complications. Recovery more frequently follows a combination of bad symptoms in the young than it does in the adult. At this age the child gets better quickly, gets worse suddenly, dies quickly, and often recovers quite unexpectedly. Sudden death occasionally happens in cases of pneumonia of the right apex in children. Cyanosis is generally the first sign of impending danger, and this is so whether it is a sign of some pericardial localization or merely a simple acute dilatation. The cases complicated with bronchitis are much more serious than the frank cases.

Pneumonia in the aged. From the age of 45 up to 60 the mortality steadily increases and averages about 35 per cent. After 60, few recover. Death is usually associated with deficient organs, and of these the kidneys are mostly at fault. The onset and course of the disease are generally insidious, and death usually occurs on the fifth or seventh day. Neither the pulse nor the respiration shows the same relative rapidity that it does in the young. The outlook is fairly good as long as there is a large amount of urine passed; a pulse of good tension, and a fever moderately high. The pulse is often quite slow and easily deceives the neophyte; later it quickly becomes rapid and feeble. Any change in frequency is ominous. A pulse of 120 in the aged is seldom recovered from. In the aged a sudden rise or fall in temperature, apathy, somnolence, and a sallow complexion are all indicative of danger. These cases that have marked delirium or stupor lasting two or three hours practically never recover. Incontinence of urine in these patients is generally a fatal omen. These old patients die from heart failure; from the extent of the inflammation; from general toxemia; from thrombosis of the coronary arteries, or from one of the complications. Toxemia and prostration are the ordinary causes of death. These patients usually die in a very short time after the change occurs.

When pneumonia is evidently contracted from another person, the disease is highly fatal. When an epidemic of pneumonia occurs in a barracks or school, or where it is manifestly contracted by large numbers, it is more fatal than any other infectious disease, averaging as high as 75 per cent. The earlier in such an epidemic a given case occurs the worse the prognosis. When pneumonia occurs among negroes the mortality is double that of whites of the same age and living under the same general conditions.

Statistically, pneumonia is a much more fatal disease in the winter months than when it occurs in the summer; one reason of this is that it is more often complicated by an influenza or septic bronchitis. In the winter in some years nearly all of the pneumonias get well, while in other years the mortality is appalling. The particular strain of pneumococcus present undoubtedly influences the mortality, but there is not nearly as much variation in virulence as there is in other infectious diseases. In some families there is a transmitted susceptibility to pneumonia. In such families an attack is apt to follow the same general course as it has in the parents or relatives. In many families frank pneumonia, as distinguished from terminal pneumonia, is the common cause of death. Any pneumonia occurring in such families, unless the attendant circumstances are extremely favorable, demands a guarded prognosis. A patient who has had one or more attacks of pneumonia is not apt to succumb to the present attack, unless there be some attending grave complications. The climate as such, *i.e.* whether tropical or frigid, does not seem to affect the mortality rate. It was formerly believed that pneumonia occurring in high altitudes had a very great mortality. Recent studies seem to disprove this statement. It has been found that soldiers living at moderate altitudes, say one mile, have as small a mortality rate as those at the sea level. On the other hand, it is well known that among miners the

mortality is very high; this can probably be explained by the fact that they live unhygienic lives and are doing hard manual labor, which render them poor subjects for the disease. It is quite possible that the rate of mortality is much higher at very high altitudes, as an elevation of two miles, than at the sea level.

Aspiration pneumonia, following the inspiration of water, as seen after resuscitation from drowning, is not particularly fatal, provided that the water is reasonably clean. The pneumonia following the aspiration of pus is usually fatal. When pneumonia follows the aspiration of large amounts of blood in the hemoptysis of well-developed pulmonary tuberculosis, the outlook is grave. When it follows such inspiration early in the disease, it is generally benign. Foreign body pneumonias, provided the foreign body remains in the lung, are, with very rare exceptions, uniformly fatal. With operation and recovery of the foreign body, there is still a mortality of 30 per cent. Hypostatic pneumonia usually occurs in connection with some other disease, and exhaustion is the most pronounced symptom. It is invariably fatal. By wandering or migrating pneumonia is meant a pneumonia successively involving different portions of the lungs. It is common in the aged, in influenza, and wasting disease, and the prognosis is always a grave one. It is hopeless if a total of more than three lobes are involved at one time. Interstitial pneumonia runs a protracted course, with high temperature.

The existence of antecedent complicating factors. When a pneumonia develops in a patient suffering from chronic nephritis, it is usually of the adynamic type. If the nephritis is advanced enough to give clinical symptoms, the combination is always a fatal one. When pneumonia develops in the course of cirrhosis of the liver, death is the rule. Valvular disease of the heart increases the danger, but if it has been well compensated previously, the danger is not as great as is usually believed. Some statisticians go so far as to say that valvular disease of the heart has no evil influence on the disease. I believe that it is a serious complication if the pneumonia be of a severe type. When compensation has already been broken, the complicating pneumonia is always fatal.

In diabetes, as evidenced by symptoms other than glycosuria, the disease is uniformly fatal. Even when the glycosuria and polyuria are the only marked evidences of the disease the prognosis remains a grave one. In those who have suffered from previous attacks of gout the outlook is very serious. If they recover, they are very apt to have recurrent attacks of pneumonia. When the disease attacks one already suffering from chronic emphysema, the result is usually fatal. The more marked the emphysema the less hope there is for the patient. A preexisting rheumatic habit has been observed to add to this gravity.

A pneumonia occurring in the course of typhoid fever usually appears in the third week of the disease and has a very high mortality. The course of pneumonia in typhoid fever is greatly protracted, resolution is delayed, and consolidation often incomplete. When it complicates a pernicious malaria, the mortality it said to be 60 to 80 per cent. With ordinary quotidian malaria, properly treated, there is little or no evil effect; with estivoautumnal malaria the prognosis is serious. The disease is very frequent, and extremely fatal in individuals suffering from malarial cachexia; complications are frequent and delayed resolution is common. In measles, after the disappearance of the rash, lobar pneumonia often occurs. The mortality is somewhat higher than in frank cases at the same age. As a complicating infection in severe gastroenteritis in childhood, the mortality is almost 70 per cent. Practically all fatal diphtheria and whooping cough cases die of pneumonia. Most patients suffering from chronic nephritis die of a terminal pneumonia. In general, it may be stated that in a pneumonia developing in the course of an infectious disease the chance of recovery is diminished 50 per cent. Of course, one must except the mild infections, such as chickenpox. Pulmonary tuberculosis furnishes a marked exception to the rule. Unless the patient is far advanced in the disease, pneumonia is a comparatively benign disease. In late stages of the disease death is very frequently due to a terminal pneumonia. Among those who are the subjects of arteriosclerosis relatively early in life pneumonia is very fatal. For this reason we find a high mortality among syphilitics, among workers in lead, and among those who do prolonged hard work, such as laborers and farmers. This accounts for the high mortality in hospital practice, because a large percentage of hospital patients come from these classes.

Pneumonia in pregnancy. The more advanced the pregnancy the worse the outlook. If delivery does not occur in the first few days the outlook is better. Most often the miscarriage occurs on the third day. The mortality, when miscarriage or delivery occurs in the first three days, is 40 per cent.; after that time, 28 per cent. The fetal mortality, unless the child be delivered within the first 24 hours, is 50 per cent.

Pneumonia complicating influenza. By far the most common disease we find antecedent to pneumonia is influenza. Generally the pneumonia begins with an insidious onset—low temperature, prostration, relatively high pulse, and low respiration rate—and all of these symptoms form conflicting elements in the prognosis. These cases of pneumonia fall within one of two general groups: The one, a mild set of cases, last a few days with few constitutional symptoms, usually involving one lobe, frequently an upper one, and terminating in resolution. A second group begin with symptoms of profound prostration, rapid pulse, and a drawn, pinched expression. These cases are apt to involve more than one lobe, persist longer than ordinary pneumonia, often wander from side to side, and their temperature falls by lysis. Unresolved pneumonia and effusions are quite common in their wake. In the aged grippe is an almost uniformly fatal complication. In those who have led lives of excess in any form the outlook is not good. Excessive use of tobacco has some effect in increasing the mortality rate. Heavy eaters with sedentary habits are not good subjects. Likewise, corpulent people bear the disease worse than the lean and lank. Those who are apparently strong and robust, but who are living under severe strain, mental or physical, do not make good subjects for this disease.

The accession of complications due to pneumonia itself. Meningitis occurring as a complication is rarely evident before the sixth day. It is usually the manifestation of a pneumococcous septicemia and is invariably fatal. Arthritis is rare and occurs oftener among men than women. It generally occurs during the latter part of the disease, or shortly after the crisis of the pneumonia. It is monoarticular in 60 per cent. of the cases. The mortality is 65 per

cent., largely as a result of the general pneumococcous infection. Death is usually due to an accompanying endocarditis or meningitis. When not so complicated, proper treatment will much reduce the mortality. Ever since the time of Grisolle pneumonia accompanied by jaundice has been regarded as a grave combination. The mortality depends on the cause of the jaundice. A mild, simple catarrhal jaundice does not appreciably affect the prognosis; when, however, it represents a true cholemia due to a diseased liver, the mortality is frightful. When it is evidence of cirrhosis it is fatal. In general, in all chronic jaundice cases the mortality is more than doubled. Peritonitis is always fatal. It is rare, but it is present in a fair proportion of cases of death from pneumonia. Femoral thrombosis is generally recovered from. Peritonitis is rare; it usually occurs about the third day. It is only seen in severe cases, and generally suppurates. Gangrene of the lung with abscess formation under medical treatment averages from 1 to 2 per cent. recoveries; under surgical measures as high as 70 per cent. recoveries have been reported. This is too good to be true; probably 20 to 30 per cent. is nearer the truth. Surgery may be expected to yield good results when the lesion is limited to one lung, when its area is circumscribed, when it is single, and when there are pleural adhesions. In general, a delirium may be foretold in the apex pneumonias of children and drunkards. Only in the latter has it much significance. True alcoholic delirium tremens often develops in people who have been steady drinkers of strong alcoholic beverages. The mortality rate is doubled by this complication. It usually manifests itself on or before the third day of the disease. Many of these cases involve the apex of the lung. If the kidney shows any marked disease, recovery is a rarity. The earlier the delirium occurs in any case of pneumonia the worse the prognosis.

The commonest complication in pneumonia is pleurisy, with effusion. Pathologically, the effusion occurs in at least 50 per cent. of all cases of the disease and is most commonly apparent on the fourth or fifth day of the disease. It is rarely discovered by physical signs. When not extensive it does not seriously affect the prognosis. When, however, the fluid rises above the angle of the scapula, in my experience it has been a fatal complication. Pleurisy that is evident only after the subsidence of the pneumonia should have no mortality *per se*. Empyema, recognized early and treated on sound surgical principles, should have a small mortality. In children 75 per cent. of the empyemas are due to the pneumococcus, and 25 per cent. are due to pyogenic organisms. The reverse holds true for adults. When the empyema occurs on the side opposite to that of the pneumonia, the prognosis is more grave than when it occurs on the same side, as it then indicates a septic pleura. When late in a pneumonia an uncontrollable fetid diarrhea develops, especially if it becomes involuntary, death is a practical certainty. Tympanitis is a serious complication; if it does not respond quickly to diet and treatment the mortality rate is more than doubled for that particular case. Hiccough, persisting in spite of all treatment, is a very serious complication; recovery is rare. The appearance of profuse cool sweats, not associated with the crisis, is an ominous sign. Herpes labiales is a sign of good omen in the great majority of cases, and mostly accompanies cases in which a sharp crisis occurs on the sixth day. There are a good many practitioners who feel that the absence of rusty sputum is a good sign. I am not so certain of this. Abundant rusty sputum, bright in color, in a thin person is a good sign. Sputum of the green-gage variety is not a good sign, and sputum of a uniform dirty orange color, like anchovy sauce, is of especially bad import. Bloody expectoration, up to the seventh day or later, was regarded as an evil omen by the father of medicine. This scarcely holds true. He also regarded the cases beginning with nasal discharge as fatal. Some believe that if there is an absence of expectoration in the second and third stages, or if the expectoration becomes scanty and difficult, the outlook is grave. Any sudden cessation of expectoration at any stage of the disease, if accompanied by tracheal râles, indicates the near approach of death. A dry tongue means a severe case. Those cases that begin with marked gastro-intestinal symptoms are apt to be very severe. Active delirium in adults, even when independent of alcoholism, is a grave sign, and it is particularly serious if it develops early in the disease. Severe pain at onset often, but not always, indicates a severe attack of pneumonia. Edema of the lungs is practically always fatal. Unresolved pneumonia has no mortality *per se*, unless there is some serious complication causing it; recovery invariably takes place, although the physicial signs may remain for many months. If a case begins with a sharp sudden onset, continuing with a fairly high temperature, say 104° to 105°, with remissions of from 1° to 2°, a respiration rate not over 32, and a pulse not over 120, and no antecedent complications, not involving more than two lobes at a time, a good prognosis may be given. In the statistics of Sears and Larabel, from the Massachusetts General Hospital, there were 949 cases. Examination of these statistics shows that 120 is the limit of safety as far as the pulse is concerned. When the pulse reaches 130, more than one-third of the patients die. With a respiration rate under 30 there was less than 9 per cent. mortality; under 40, less than 15 per cent. mortality. A fairly high temperature range is a good sign, as it shows a decided reaction; a low temperature, with signs of prostration, is of very grave import; a low temperature, without signs of prostration, is, of course, a good omen; it may, however, mean a longer duration of the disease than is common. A persistently high temperature over 105, with very slight remissions, is of serious import. A temperature of 107, lasting more than 12 hours, is always fatal. A temperature over 106 in an adult, lasting 24 hours, is seldom recovered from.

Leucocytosis. In general, a fairly high leucocytosis of, say, from 15,000 to 35,000 is a good sign, provided that there is no evidence of a profound infection. A low leucocytosis in the presence of several symptoms, or accompanied by prostration, is a bad omen; otherwise it has no especial significance. In general, the leucocytosis represents the reaction of the body to the organism. The eosinophiles disappear until a day or two before the crisis; from then on increasing up to 5 or 6 per cent. Their reappearance is a very hopeful sign. The disappear- of iodophilia is said to be a good sign. The leucocytosis generally decreases with the crisis. It does not decrease with the pseudocrises. Then, if the critical drop in leucocytosis does not occur with the sudden drop in temperature, we are justified in believing that the actual crisis has not occurred, and may so warn the attendants. When resolution is delayed the leucocytosis persists, and when there is an extension of the process in the lung there is an increase

of the leucocytosis. Doubling of the leucocytosis generally means empyema. Death from mechanical interference with respiration is rare. The extent of the process in the lungs in general has little to do with prognosis, provided not more than two lobes in the same side are involved. Double base pneumonia always means a severe case, and in those over 50 years of age it is practically always fatal. Extension of the consolidation at an advanced stage of the disease, say after the third day, is indicative of a severe type. Before the crisis the presence of liquid râles, where there were none before, is of serious import.

The statement of Von Jurgensen, that patients who die of pneumonia are killed by cardiac insufficiency, is generally accepted, yet there is evidence tending to show that the cause of the lethal issue is often a central one and is due to toxemia. When all is said and done, our mainstay in prognosis is the condition of the heart. Any change in the pulse whatsoever, unless it be a diminution in the number of beats, is a sign of great danger, and the earlier any such change occurs the worse. One must expect a rise and fall of one to five beats per minute with the regular rise and fall of temperature, but if under corresponding conditions there is an increase of even two beats per minute over the preceding day, there is grave cause for alarm. Mackenzie says: "In all cases that I have met, when the pulse showed even an occasional irregularity before the crisis was reached, death supervened. I have not found a single exception to the rule for over ten years, and while extended experience may prove it fallacious, irregularity of the pulse with pneumonia must at all events be looked on as a serious symptom. In pneumonia the amount of arterial pressure, the rate of the pulse, and its rhythm are each of them the most important indication we possess. Within a few hours after a rigor the fatal issue may be too plainly foretold by the character of the pulse. I have rarely seen an adult with a pulse of 140 that recovered."

Most of us have seen cases that are exceptions to the statement made above by the distinguished cardiac specialist, yet in the main his dictum holds good. In young patients, already suffering from arrhythmia due to organic disease, the rule certainly does not obtain. Nervous patients often have a temporary irregularity due to apprehension; this is of no consequence. In many children, for a few days previous to the crisis, arrhythmia is quite common and has no significance, nor has the arrhythmia induced by large doses of digitalis any consequence. I have not been able to satisfy myself that blood pressure determinations offer any basis for prognosis.

As in all infections, the character of the pulmonic second sound is an important sign. As it is watched and becomes weaker hour by hour and day by day, it is known that the general condition of the patient is not as good as the day before, and thus it is a guide to the patient's general condition. The late A. H. Smith was wont to say that he had never seen a case with sharp, distinct pulmonary valve sound in which a favorable prognosis as to the immediate future was not justified. A feeble pulse that is frequent in relation to the respiration and temperature is a bad sign, as a large number of these cases perish. Gallop rhythm is always fatal. In many cases the crisis itself is not such an alarming picture as it has generally been pictured in the textbooks. Patients do die during the crisis itself, but death usually occurs before the time of the crisis. However, a fall in temperature without a concomitant drop in the rate of the pulse, and frequently of the respiration, is always most serious, and even a drop of the pulse rate and the temperature, if it is not associated with a drop in the frequency of respiration, is always a reason for alarm.

The two general conditions that betoken an approaching dissolution in most cases are the presence of the so-called Romberg Passler syndrome, and, second, the failure of the right heart. In the first instance, the dilatation of the blood-vessels in the splanchnic area causes the normally low blood pressure to sink much lower; this is accompanied by an increased rapidity of the heart. Shortly afterwards tympanitis becomes a marked symptom. The patient then looks as though he had been bled excessively. He has the appearance of profound shock; the pulse becomes irregular and this is often followed by delirium, hallucinations, restlessness, and later stupor and coma; although occasionally the heart becomes much slower, the patient invariably dies when this symptom is well developed. In the second class the patient is cyanotic and there is great dyspnea, the jugulars are full and pulsating, the heart dullness is sometimes increased to the right, and the liver dullness almost always increased. Occasionally such a patient is saved; they usually die of asphyxia. When death has begun, the earliest indication of which is an increasing dyspnea, and a rattle with each respiration, which persists after coughing, recovery is unlikely.

It would be difficult to get a unanimous opinion among any group of medical men of the present day that any form of treatment has any specific value as a cure of pneumonia. Personal views as to their ability to alter the prognosis by this or that treatment will always prevail. Certainly the prognosis can be decidedly influenced by the treatment and prevention of symptoms, complications, and sequelæ, but it is difficult to measure this in a concrete way. Last, but by no means least, in making a prognosis we must take into account the mental attitude of the patient. Hopefulness, determination to win, and patience sometimes prevail when there does not seem to be a glimmer of hope. These mental phenomena cannot be measured, but, when coupled with confidence in the physician, undoubtedly have a favorable influence. Possibly the loss of this personal confidence in the physician is an added factor in the high mortality in hospital practice.

Necessity of Removal of Adenoids and Enlarged Tonsils.—J. N. Roy says that there are many reasons why we should urge the removal of adenoids and tonsils when enlarged. The nose has the function of removing from the air the irritating particles and bacteria which reach it, and of raising the temperature of the air before it enters the lungs. The removal of adenoids prevents adenoid athrepsia, arrest of development of the bones of the face and thorax, infections of the respiratory tract, inconveniences of obstruction of the nose, dangers of mouth breathing, deafness and suppurations of the ear structures, reflex nervous phenomena, infectious diseases, and retarded mental development. The removal of hypertrophied tonsils prevents respiratory and digestive infections, ear troubles, reflex nervous troubles, aggravation of diphtheria, and infection of the glands of the neck.—*Le Journal de Médecine et de Chirurgie.*

A DESCRIPTION OF A METHOD FOR MEASURING EASILY AND EXACTLY THE DOSE OF THE X-RAYS IN RONTGEN THERAPY.*

By JOHN BETHUNE STEIN, M.D.,

NEW YORK

PROFESSOR OF PHYSIOLOGY AT THE NEW YORK COLLEGE OF DENTISTRY; ASSISTANT IN THE DEPARTMENT OF GENITOURINARY DISEASES, COLLEGE OF PHYSICIANS AND SURGEONS, MEDICAL DEPARTMENT OF COLUMBIA UNIVERSITY, NEW YORK.

In .r-ray therapy, the direct measurement of the Röntgen-ray quantity or dose outweighs all the physical factors which contribute to the production of the rays. Ever since radiotherapy was instituted, various attempts have been made to measure the .r-rays directly, instead of measuring the electric elements used to produce them, and many kinds of apparatus have been devised for posological estimates, which are based on the well-known phenomenon of the change in color of certain substances under the action of the .r-rays. Villard was the first to show changes in color of platino-cyanide of barium under the influence of the .r-rays. This salt, when exposed for a sufficient time to the .r-rays, changes from green to a bright reddish brown, and the action seems to be proportional to the quantity of rays absorbed. This reaction is known as Villard's reaction, and is applied in a practical manner in instruments used for measuring the dose of the .r-rays, under the name of the Sabouraud-Noiré reaction.

The use of the radiometer of Sabouraud and Noiré, which measures the Röntgen rays by means of a change in color of small pieces of paper on which a thin layer of platino-cyanide of barium has been fixed, has been most extensive, and taken all in all is one of the best instruments we possess for this purpose; nevertheless, the measuring qualities of the instrument are not faultless. It has obtained a wide vogue in spite of a failure, the greatest of failures in a measuring instrument, not only in not having a graded scale, but possessing no scale at all. Only a single dose can be read from the scale; all other doses, even ordinary graduations of doses, must be estimated. The single attempt of Bordier to devise a graduated scale of four grades must be considered a failure.

The above mentioned deficiency and faults, Holzknecht has endeavored to overcome by devising an instrument (Radiometer of Holzknecht, Fig. 1) which by means of a graded color scale (G. S. Fig. 1) and a continuous color scale (C. S. Fig. 1), definite grades of color (from green to a reddish brown) can be read from the former, and any grade of color (green to reddish brown) from the latter; and further, the color in the two scales can be compared. The technical difficulty in manufacturing the instrument lies in the preparation, not only of a color band or scale (C. B. Fig. 1), but graded and continuous color scales which will together automatically lend themselves to the correct reading of a preparation of platino-cyanide of barium which has been exposed to the action of the .r-rays. The instrument is constructed of hard rubber, on the right side of which (Figs. 1 and 3) is a runner or slide (Sld. Fig. 1). On the right half of the instrument, where the numerals are seen, is the so-called reading scale (R. S. Fig. 1), while into the runner of the slider (Sld. Fig. 1), which lies (in Figs. 1 and 3) upon the upper part of the reading scale, are inserted the reaction piece (R. P. Fig. 1) and the scale piece (S. P. Fig. 1). The reaction or measuring piece is made of cardboard, upon one end of which is the reagent, a thin layer of platino-cyanide of barium in the form of a half disk. (See Fig. 1 H. D. R.) The scale piece has a similar half disk on one side of its end (Fig. 1 H. D. S.). When these two pieces are brought together so as to form a right angle, a complete green disk or small pastille is formed by the juxtaposition of the two half disks. (See Figs. 1 and 3.) The continuous scale (C. S. Fig. 1) and the graded scale (G. S. Fig. 1) are formed by covering the disks of the platino-cyanide of barium (G. S. Fig. 1) and the half disks of the same substance on the scale piece (S. P. Fig. 1) with a strip of celluloid, the color band or color scale (C. B. Fig. 1), in which the intensity of color

(reddish brown) increases from above downward. The six disks (G. S. Fig. 1) of the platino-cyanide of barium on the graded scale, under the colored celluloid band or color scale, vary in color from above downward, from a light green to a marked brownish yellow. There are six grades of color, representing six different strengths of deepening (browning) in color. The half disk of the same material on the scale piece (H. D. S. of S. P. Fig. 1), which is also under the colored celluloid band, may show the same colors as those of the six disks on the graded scale, when placed opposite the same; or intermediate grades of color, when placed between them. There is, in other words, a continuous difference in shade or color, depending upon the position of the half disk under the celluloid band. This half disk of the scale piece, which has not been exposed to the action of the .r-rays, and

*This article has been written at the suggestion and under the direction of Dr. Guido Holzknecht, Privatdozent for Medical Radiology at the University of Vienna and Director of the Institute for Diagnostic and Therapeutic Radiology in the Allgemeines Krankenhaus, Vienna, under whom the writer served for some time during the past year.

has been placed in the slider under the color band, has its characteristic green color at the clear end of the color band, but when it is moved along the color band it gives out different grades of color from green to reddish brown, corresponding to a disk which has been subjected to different degrees of browning by the *x*-rays. The half disk at the end of the reaction piece (R. P. Fig. 1) lies under a piece of uncolored, transparent celluloid (at C. Fig. 1 and at 2, Fig. 2), and therefore has its characteristic green color. It is this half disk of platino-cyanide of barium on the end of the reaction piece (H. D. R. on R. P. Fig. 1 and 7 on 3, Fig. 2) which changes color when subjected to the action of the *x*-rays. The changed color of the half disk of the reaction piece is compared with the color of the half disk of the scale piece, and the slider moved so that a disk of uniform color is made by the two half disks, and the composite color of the disk, so formed, is compared with the disks of the graded scale. It is most important that the two half disks be brought into exact juxtaposition in order that the gradations in color may be best appreciated. By comparing the color of the two half disks the color intensity of the half disk of the reaction piece can be empirically established. When the two half disks have the same color a reading is to be taken from the scale under the slider.

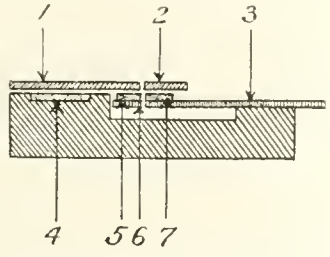

FIG. 2.—Transverse Section of Radiometer: 1, celluloid color band or color scale (C. B., Fig. 1). 2, transparent celluloid covering for 7, which is the half disk of platino-cyanide of barium on the reaction or measuring piece. 3 (R. P., Fig. 1), reaction or measuring piece. 4, a platino-cyanide of barium disk on the graded scale (G. S., Fig. 1). 5, the half disk of platino-cyanide of barium on the scale piece. 6 (S. P., Fig. 1), scale-piece. 1 and 4 equal the graded scale. 1, 5 and 6 equal the continuous scale.

The optical exactness of the apparatus is evident, as is seen in such a chromometric apparatus as the hemometer of Fleischl, where the scale and the working of the same closely resemble the instrument under consideration. The reading scale of the instrument is gauged to the first and original dose-measuring instrument, the chromoradiometer of Holzknecht, which for the past five years has been withdrawn from the market by the inventor on account of the difficulty experienced in having it manufactured, especially regarding the colored celluloid band or color scale.

The unit 1 H. (this sign has naturalized itself in Röntgen literature) is one-third of that quantity of radiant energy from an *x*-ray tube which can induce a light uniform inflammatory reaction of the skin of the face of an adult. This (1 H) corresponds to 2 X units of Kienböck's instrument, and about 5 H are necessary in order to reach the tint B of the original instrument of Sabouraud. Thus: 1 S = 10 X = 5 H. In order to reach the maximum action of the rays without reaction, the following units must be applied: For middle-aged adults we apply to the face 2 H, to the head and joints 3 H, and to the body 3.5 H to 4 H; to children 1 H, 2 H, and 3 H, respectively; to aged individuals 3 H, 4 H, and 5 H, respectively. The dose may be given at one sitting or divided. There should be an intermission of three weeks between doses. By means of this instrument even ¼ H can be read. It is ten to twenty times as exact as Holzknecht's original instrument, and is accurately adjusted for medium tubes (Benoist-Walter Scale V). When harder tubes are used, as is the case when deep-lying tissues are to be treated, the same colors are correct, only their respective values are to be reduced a little.

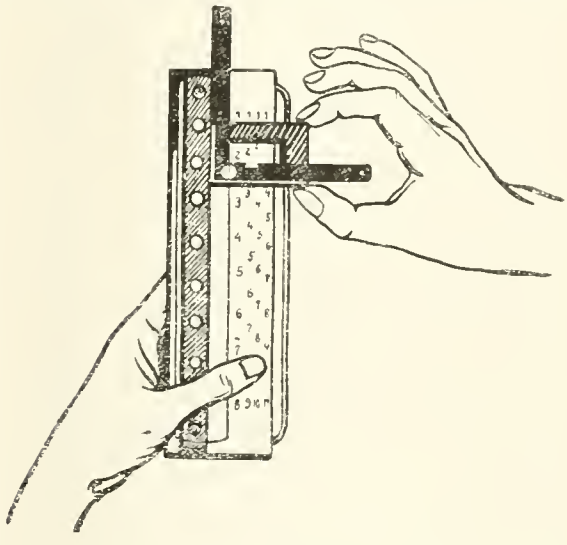

FIG. 3—Manipulation of Instrument.

Application of the Instrument.—The color band or scale should be kept in its special box in order to prevent its being bent or injured, especially when the instrument is used at only long intervals. The color band should be inserted with its lighter colored, diagonally cut end above, and the darker part below. The scale piece is then inserted in the slider and the instrument is ready for use. The measuring piece or reaction piece is fastened to the tube and acted upon by the rays at a distance one-half the so-called focus distance of the tube. When one desires to know if the limit of the intended dose has been reached, the reaction piece is to be taken from the tube and shoved in the slider of the reading scale. The slider is to be moved along the reading scale until the half disk on the reaction piece, which has been changed in color by the Röntgen rays, is of the same color as the half disk on the scale piece, so that the two form a homogenous colored disk. When a reading is to be made, the illumination of the scale should be by an electric light bulb and not daylight, as by daylight the contrast is not great enough. It is also expedient not to have the electric light bulb too near; it should be above and behind the examiner. The slider should be at first drawn from the lighter end of the color band to a point where the two half disks have about the same hue, and then moved slowly up and down until the color of the two are exactly the same. For a control the same should be done, starting from the darker end of the color band. From the foregoing it is clearly seen that the application of the instrument is no innovation to the physician who has used a Fleischl's hemometer, and one soon becomes proficient with the use of the radiometer. On the upper edge of the measuring or reaction piece is a small cut-out area (Fig. 1 on R. P. at N., and Fig. 3) marked on either side by a red line. It is between these two red lines that the reading is to be taken from the

reading scale beneath. (Only one line of numerals is used on the reading scale with this measuring piece; the other figures are for other measuring pieces.) If the reading is too little, for example, 2.5 H instead of 3 H, the exposure to the rays should be continued.

In order to produce the original light green color of the half disk on the reaction piece, the half disk should be exposed to diffuse daylight (not direct sunlight). For ordinary use the reaction piece can be used three to six times, but after each exposure to the rays all the change of color in the disk must be removed, otherwise the exactness of both the reaction piece and the instrument itself suffers so far as their measuring qualities are concerned. That the operator may not surpass the desired quantity in applying the *x*-rays, he takes his readings so much more often as he is less skilled in Röntgen therapy. All instruments which are used for measuring doses naturally fail in their object if one neglects to read them, and further, any apparatus used for measuring the dose, which automatically interrupts the dose (exposure), does not give the desired result. It is therefore important to have an alarm clock, which will call the attention to the reading of the instrument. The novice will do this at very short intervals, till little by little experience permits longer intervals. At each exposure about three readings should be taken. Never should a period of time be allowed to expire without taking a reading, which is equal to half the time thought to be necessary for reaching a full dose. It is not necessary each time to undertake an exact reading of the dose to be given, but the graded scale can be used for a preliminary reading, as follows: The half disk of the reaction piece is brought near one of the disks of the graded scale for comparison, or one-half of a disk of the graded scale is covered by the half disk of the reaction piece. A similar simplification of a reading from the continuous scale (C. S. Fig. 1) can also be obtained by comparing the half disk on the reaction piece with that on the scale piece. The object of these two methods is to ascertain if the desired dose will soon be reached. When subjecting the half disk on the reaction piece to the action of the *x*-rays in the presence of daylight, the reaction piece should be covered with black paper. In subdued daylight or artificial light, which conditions are desirable for the working of the tube, the foregoing precaution is quite unnecessary.

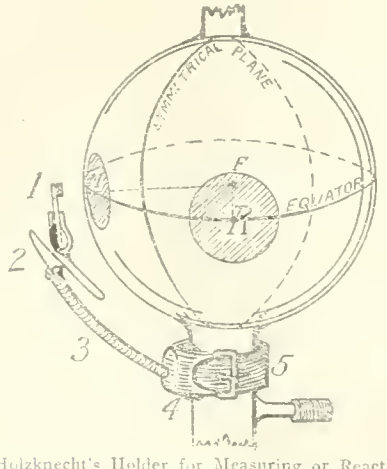

FIG. 4.—Holzknecht's Holder for Measuring or Reaction-piece: F, center of tube. R, radiation field. M, Measuring field. R and M are on the equator and equally removed from the symmetrical plane. 1, reaction piece. 2, 3, 4, 5, holder for reaction piece made of wire, bamboo, cork and elastic.

The Relation of the Reaction or Measuring Piece to the Radiation and Measuring Fields.—The measuring part of all direct-measuring instruments should be placed in the measuring field of the Röntgen tube, which is placed symmetrical to that of the radiation field. If this is not done the reading will be faulty, for there is a difference in the light emission at different parts of the *x*-ray tube (Kienböck). The application of the measuring piece to the *x*-ray tube is best understood when the tube is taken in the hand and several planes in and about the same are studied. The plane formed by the continuation outwards of the anticathode is known as the anticathode plane. A circle drawn around the tube at this plane divides the glass wall into two parts. The part in front of the electrode is where the rays are, and behind the electrode there are none. The patient is placed before the electrode and the examiner (out of the rays) stands behind the electrode. The great circle which can be drawn at right angles to the long axis of the tube is known as the equator (Fig. 4). At this point the wall of the tube is the thinnest (for the globe has been formed by a drawing out of a glass tube), so the greatest intensity of the rays will be at this part. The plane, which can be imagined as drawn through the three electrodes and which divides the tube into two symmetrical halves, is known as the symmetrical plane (Fig. 4). It is from here that the radiation takes place equally in the two symmetrical halves of the tube. At the periphery of the symmetrical plane the radiation is but little and becomes strong in the region of the anticathode plane. In order that both the part of the body which is to be treated and the reaction piece of the instrument be exposed to an absolutely equal light emission from the tube, three circles should be drawn upon the tube, at first by means of a glass pencil, later mentally; one in the anticathode plane, the second in the equator, and the third in the symmetrical plane. Two places should be selected at the circumference of the tube, which lie on the equator, which are equally distant from the symmetrical plane and at some distance from the anticathode plane (see Fig. 4 at the points marked R and M). Through one part (R) the rays pass to the body of the patient; through the other (M) to the measuring or reaction piece. The point of the tube which has been selected, from which the rays are to pass to the patient, radiation field R, should be placed directly over the part to be treated, and the reaction piece of the instrument should be fastened near the circumference of the tube at the corresponding point, measuring field M. The measuring piece should be placed parallel to the circumference of the tube, at right angles to the rays, and at a distance one-half that at which the skin of the patient is focused (skin-focus distance). In order that this distance, and the place where the rays are focused on the measuring piece may not change, it is best to fasten the measuring piece to the tube. A simple form of holder for the measuring piece is shown in Fig. 4. The holder, which is constructed of cork (4), bamboo (3), and copper wire (2), which holds the measuring or reaction piece (1), is fastened to the neck of the tube by means of an elastic band (5). The holder can be easily revolved around the neck of the tube so as to bring the measuring piece, inserted at its distal end, anywhere on the equator of the tube. The distance of the place where the rays are focused on the skin (skin-focus distance), and on the meas-

uring piece (measuring-piece focus distance), from the center of the tube cannot be measured directly, as we can only measure from the periphery of the tube. The length of the radius of the tube must be taken into consideration, which is (as can be obtained by means of a tape measure) one-half the diameter or 1/6 the circumference, usually 8 to 12 cm. If the focus distance of the skin is 30 cm., the radius of the tube 10 cm., the distance of the glass of the tube from the skin would be 20 cm., and the distance of the measuring piece from the glass should be 5 cm. The plane of the radiation field, where the measuring piece should be, is 15 cm. distant from the center of the tube. Radius of tube (10 cm.) + distance from glass of tube to measuring piece (5 cm.) = 15 cm., or one-half the focus distance of the skin. A focus distance of 30 cm. for the skin and 15 cm. for the measuring piece is said to be quite sufficient for all ordinary treatment of skin lesions and lesions in deeper-lying organs. If one wishes to administer a greater dose of the rays which cannot be read, or rather exactly read, on the scale; for example, 20-15 or 10 H, then it is necessary to fasten the measuring piece on the body of the patient. The skin is then in focus instead of the focus being at a distance one-half that of the skin, and the readings have four times their original value: 2 = 8, 3 = 12, and 4 = 16 H.

The measuring instruments at present in use are faulty in that they require the presence of an assistant, and even with one, several measurements must be made before the correct measure is obtained. In order to measure the distance of the circumference of the tube from the skin, Holzknecht cuts a thin stick to the desired length (Fig. 5 A). This is called the distance measure. At one end of this he fastens a rubber cup, which by suction, when lightly pressed, will remain upon any point on the surface of the tube. It may at times be necessary to moisten the cap with vaseline in order to effect the suction. To the other end (c) can be bound a tuft of cotton covered with gauze. The end of the stick (at a) is now made fast to the radiation field (Fig. 4, R) of the surface of the tube. The tube and stick attached to it can be so moved about that the end of the stick (c) presses lightly over and against the part which is to be treated.

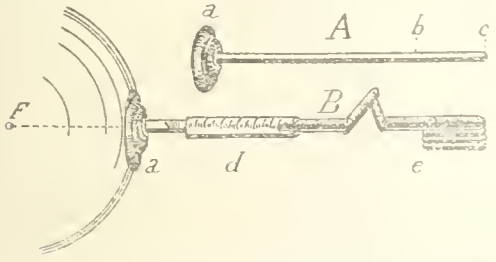

Fig. 5.—A and B, two forms of distance measures (Holzknecht). F, center of tube, *a*, rubber cap; *a b* equal 15 cm; *b c* equal 5 cm. *d*, For measuring the reaction-piece focus distance. *e*, For measuring the skin-focus distance.

Another form of distance-measuring stick is shown (B in Fig. 5), attached to the tube by the suction of the rubber cap. The center of the *x*-ray tube is shown at F, Fig. 5. This latter instrument can be folded up and extended as desired, and is marked off in centimeters. By fastening one or other of these instruments to the tube the required distance of the skin from the center of the tube may be easily and quickly obtained. The distance from the center of the tube to where the reaction piece of the instrument is to be placed may also be easily obtained by making a notch on the stick A, at a point b, 5 cm. from the end of the stick, and using this as a measure to determine at what point distal from the circumference of the tube the reaction piece should be placed. Slight pressure on the surface of the rubber cap is sufficient to remove it from the surface of the tube. These distance measures are also of use in radiography. It is known that both a hard tube and not too small a focus distance, at least 30 cm., are necessary, in order to attain a sufficient influence upon deep-seated processes. The filtration of the rays through glass, aluminum (0.5 mm.) or leather (5 mm.) augments their penetrating power and affords protection against the weaker radiations. This is of special value where the skin is to be protected. When the filter is used the reaction piece should also be covered with a small piece of the same material, and both clamped together in the carrier for the reaction piece (2, Fig. 4), and then subjected to the radiations from the tube. As a control and in order to actually know if the necessary deep penetration of the rays takes place, and that a continued degree of hardness of the tube is maintained, there is furnished with the instrument a "depth measure" (a modification of Kienböck's), which consists of a small sheet of aluminum, 0.5 mm. thick, which absorbs about as much of the rays as would a layer of soft tissue 0.5 cm. in thickness. In applying this depth measure the measuring piece is to be subjected to the radiation, both when covered and not covered by the aluminum sheet. If with an uncovered measuring piece reading 4 H, the covered one reads 3 H, it means that the penetrating power of the rays is considerable or that the tube is hard (Benoist-Walter Scale VI). The penetrating power is less, if with an uncovered measuring piece reading 4 H, the covered one reaches only 2.5 H, corresponding to a medium tube (Benoist-Walter Scale V), and the tube is quite insufficient if the covered measuring piece shows only 2 H. This latter corresponds to a soft tube (Benoist-Walter Scale IV). The tube absorption is then 25 per cent., 37.5 per cent., and 50 per cent., respectively. After use, the half disk or test body (H. D. R. Fig. 1) on the reaction piece can be restored to its original color by exposing it to diffuse daylight for about twenty-four hours. We can use for this purpose a piece of cork into which pins have been inserted, and upon these we can hang the reaction piece. A portable stand for this purpose, made of aluminum, is shown in Fig. 6.

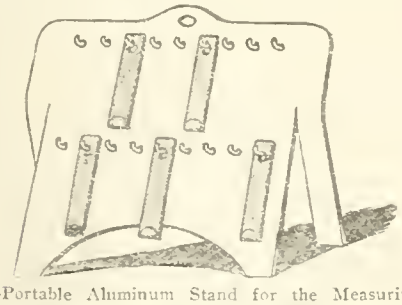

Fig. 6.—Portable Aluminum Stand for the Measuring-pieces.

After using the reaction piece several times, it is impossible by exposure to light to restore the original color to its reacting part or half disk of platino-cyanide of barium. This is due to the fact that the reacting half disks of platino-cyanide of barium have been warmed either by the sun in the

process of restoring their original color or by the rays from the tube. In order to avoid this, the reaction piece, when it is intended to restore its original color, should neither be hung upon nor put upon such places about the window as are exposed to the sun or have been warmed by it, but hung upon some portable stand. The reaction piece should never be brought nearer the tube than a distance of 1 cm. The reaction pieces which have had their original color restored them should be kept in a small box impregnated with lead, which is furnished with the instrument. After the half disk of platino-cyanide of barium on the measuring piece has been restored to its original color, it should always be compared with the half disk of the same material on the scale piece. The platino-cyanide of barium half disks on the scale and measuring piece should always be compared preliminary to measuring the dose of the x-rays.

To Clean the Instrument.—The measuring piece and scale piece should be removed and the instrument dusted with a piece of gauze. The run for the scale and measuring piece on the slider can be cleaned by a piece of chamois fastened on a rubber stick. This is furnished with the instrument. The slide which holds the scale and measuring piece can be moved up and down and the reading scale wiped. The graduated scale can be wiped off with a slightly moistened piece of gauze. When the scale piece becomes too dusty it is well to replace it by a new one.

COMPARATIVE LONGEVITY OF THE SEXES.

By A. H. STEWART, M.D.,

LAWTON, OKLAHOMA.

Some one has said that the greatest mystery in all the world was a woman who was not herself a mystery. From the earliest recorded times women have been spoken of as the weaker sex, as frail, delicate creatures. Eminent writers have asserted that aside from their natural constitutional frailty, owing to their functional periodicity, women were invalids one-fifth of their time, to say nothing of gestation, with which married women were burdened much of the time. Yet the dawn of the twentieth century finds us with abundant proof of woman's physical superiority over man when tested by length of years, the power to endure suffering, and resist disease.

In 1890 the United States census showed that there were at that time 3,981 centenarians in this country, of whom 2,583 were women and 1,398 were men. From 1866 to 1885 the yearly average deaths of centenarians in France was 46 women and 27 men. The census taken in Prussia in 1885 showed 3,564 women and 2,080 men over 90 years of age: 341 women and 306 men between 95 and 100, and 260 women and only 72 men over 100 years of age. According to the latest available statistics in India there were 247 female and 133 male centenarians in that country. Out of 89 centenarians who died in England during the year 1883, 79 were women and 10 were men, while out of 21 centenarians who died in Scotland in 1895, 16 were women and 5 were men. S. G. Humphry, in his extended studies of old age, was able to give a detailed account of 36 female and of only 16 male centenarians, while T. E. Young, in 1899, was able to find 15 cases of women living to ages between 100 and 106 years, but of only 7 men. During the year 1910 I took clippings from newspapers and periodicals of 23 centenarians who were then living or who died during that year. Of these 17 were women and 6 were men. But it is useless to multiply statistics, for, from whatever source, they all show the great preponderance of women in the older population, and the greater the age the greater is this preponderance.

The mystery of this tenacity of life in woman still remains a secret. Some cynic, with little regard for gallantry, has suggested that probably it was due to the innate tendency of women to have the last word. A comparison of the size, manner of development, and metabolism of the two sexes reveals only an occasional faint glimpse of some vital process which we think might throw some light on the subject, and all else is a sealed book.

At birth boys are slightly larger, both in height and weight, and continue in the lead until the beginning of puberty; then girls pass them, both in height and weight, for about two years, when the boys again take the lead, and complete their growth at about 23 or 24, while girls complete their growth at 19 or 20. With this brief exception, males excel in height and weight throughout life. Relatively, woman's head is smaller, her neck and limbs shorter, and her body longer than man's. The internal organs, the brain, heart, lungs, liver, and kidneys, are smaller in woman than in man. Physical strength and vital capacity, as tested by lifting weights and breathing air into a spirometer, are at all ages greater in males than in females. If either height or weight, physical vigor or vital capacity, therefore, be taken as an indication of superiority, we find little evidence for the unquestioned tenacity of life and power of resisting disease in women. Nevertheless, when we turn to natality and mortality statistics we find the strange condition of an excess of males in the younger population, especially at birth, and an excess of females in the older population, especially in extreme old age. By taking the average birth rate of thirty-two small European countries and a few of our own States, we find that for every 100 girls born there are slightly more than 105 boys born. In some countries the difference is as great as 120 boys to every 100 girls. Among stillborn children the difference is from 120 to 140 boys to 100 girls. The birth rate of boys is greater among Jews everywhere, especially among Russian Jews, than among Christians. The larger size of the head of boys is probably a factor in their greater mortality at birth and is probably a factor in the greater number of boys who die during the first few hours after birth, but it can hardly be a factor in the larger number of boys than of girls who die during the first two or three years of life. After the third year there does not appear to be any special difference in the mortality of the sexes until after thirty or thirty-five, when the ratio turns in favor of women, and continues in their favor until about seventy, when there appears to be but little difference until eighty-five, after which the difference is more marked the further we go toward extreme old age. At about eighteen, the age of chlorosis and anemia in girls, there appears to be a slight increase in the female death rate, but it is still but little, if any, higher than in males of the same ages.

This tenacity of life in females is seen in all the zymotic diseases, especially in those diseases which chiefly affect children. Whooping cough and diph-

theria only appear to be more fatal in females than in males. Whether correctly or not, this has been attributed to the smaller size of the throat in females. Notwithstanding the greater susceptibility, especially later in life, of females to most of the infectious diseases, attacks of most of them are more liable to terminate fatally in males than in females. During childhood there appears to be little difference in the susceptibility to or fatality of either cholera, smallpox, or influenza in the sexes, yet, while adult females appear to be more susceptible to all, especially the first two, all are believed to be more fatal in adult males. At one time typhoid fever was thought to be slightly more fatal in females than males, but more recent statistics have clearly disproved this. Mortality from pulmonary tuberculosis was formerly greater among females, but now statistics show it to be greater among males. Except biliary calculi, then, cancer is the only disease common to both sexes from which adult females suffer more than do adult males, but the rate of increase of cancer is now much greater in men than in women. Thus, the rate of increase in Great Britain from 1870 to 1896 among males was 153 per cent. and in females 72 per cent. All authorities appear to agree that the probabilities are that in the remote past, at least, insanity was slightly more frequent in men than in women, but that, while the present rate of increase is probably greater in women, the attacks are far more serious in men than in women. Women appear to suffer more from emotional and maniacal insanity, and recover oftener than men, while men suffer more from serious brain lesions and from paralysis of the insane, and as a consequence offer less hopes of recovery. The precocious maturity of woman leaves her, if not less developed and more primitive in her psychophysical organization, it does leave her nearer to childhood, nearer to nature than man. Thus, being more under the influence of the vasomoter centers, the neuromuscular ruler of organic life, woman, like the child, responds more readily to external and internal stimuli than man. In other words, it is largely through these primitive nerve centers, rather than through the higher cerebral centers, that woman gets her special susceptibility or affectibility, and, for this reason, from the earliest times she has figured so prominently in all psychic phenomena which are characterized by a decreased control of the higher and increased activity of the lower nerve centers, such as hypnotism, mesmerism, and animal magnetism. It is this special susceptibility of women, too, that renders her more liable to attacks of hysteria, neurasthenia, emotional states, and the milder forms of insanity. Instead, however, of this special affectibility being an evidence of constitutional frailty, as has been supposed, it appears to serve as a distinct advantage, acting somewhat as a sentinel or outpost to ward off attacks of more important centers. Likt a buffer State between two belligerent nations, this affectibility appears to act somewhat as a barrier against attacks of the more fatal forms of mental affections. So, too, woman's well-known tendency to early physical exhaustion serves to protect her from the fatal crash that often comes to man from overexertion. "He who fights and runs away may live to fight another day." When the emotions, the affections, however, stimulate to activity, as in the case of nursing sick friends, it appears that women can endure more hardships, especially in the loss of sleep, than men can. Women also bear the hardships and privations of prison life better than men do. Women seldom, if ever, die of nostalgia. Again, some hold that possibly the functional periodicity of woman, which has been generally considered to be an evidence of her frailty, may in some mysterious way be a factor in the longevity of the normally healthy woman. Man is said to travel a straight road, physically, from the cradle to the grave, while woman travels by a series of circles. In other words, man lives on a monotonous level plane, while woman lives either on the crest or in the trough of an ever-changing tide, or, as Ellis puts it, on the upward or downward slope of a curve. During the most active period of man's life his metabolism, his excretion, and secretion are daily, monthly, and yearly about the same, while woman's metabolism depends somewhat upon the place she occupies in her periodic cycle. Just what takes place in metabolism in the normally healthy female at different points along this curve has not been satisfactorily ascertained, but that there are variations, corresponding somewhat to the different degrees of life intensity, there appears to be little doubt. Even if there be no impetus given the cells during the highest physiological intensity of this period that would tend to establish a higher metabolic cycle, the very fact of the existence of such a cycle serves its negative purpose of shielding her, for a few days at least, each month from the stress and strain of life's conflict. Again, the claim, if well founded, which is doubtful, that married women live longer than unmarried women has given rise to the suggestion that possibly the fulfilment of the maternal functions is a factor in her longevity. But, since it is also claimed that married men live longer than unmarried men, the advantage, if any, is probably found in the difference in the social conditions of the married and unmarried.

A point of interest in this connection, perhaps, is that, with the exception of the first three years of life, woman's superiority over man does not really begin until after thirty or thirty-five years of age, while her greatest weight is not usually attained until at or about the climacteric. Another point of interest, whether of much importance or not, is that the thyroid gland, which plays such an important though somewhat mysterious part in nutrition, is much larger, has a much wider physiological range, is more intimately bound up with the reproductive functions, and continues its functional activity longer in woman than in man. When we turn from these unprofitable speculations to a consideration of the metabolic processes in the blood and tissues we still find ourselves just as far from our goal. This is especially true if the number of red blood corpuscles and the amount of hemoglobin found in the blood be taken as an index of physical vigor and vital resistance, for all physiologists agree that woman's blood has fewer red corpuscles, contains less coloring matter, is of lower specific gravity, and is more watery than man's blood.

The amount of urine excreted by woman is slightly less absolutely, but relatively it is much greater, while the amount of solids excreted is absolutely and relatively smaller than in man, thereby indicating a less active metabolism and consequently less wear and tear of tissue in woman than in man. This is said to be indicated also by woman's greater susceptibility to cumulative poisons, as in the case of arsenic and lead, while her affectibility is indicated by her susceptibility to nerve poisons, as alcohol and opium.

The other chief points of difference in favor of woman appear to be that the specific gravity of the blood plasma is slightly greater in woman than in man; the specific gravity of the blood, which, during middle life is from three to five degrees greater in man than in woman, tends to fall more rapidly and more regularly in man than in woman in old age. So, too, the vital capacity, the amount of air that can be expelled into a spirometer, which is normally much greater in man in early and middle life, but after forty is reduced in both sexes; but the decrease is much greater and more regular in man than in woman.

In man, as in nearly all animals, the pulse rate is slightly slower in males than in females, in the proportion of 72 per minute for men and 80 for women. But as slowness of pulse, like slowness of respiration, nearly always goes with increased weight, the difference is probably no greater than would naturally be expected. In old age woman's pulse rate is inclined to increase slightly more than man's.

Woman excretes less carbonic acid and therefore is in less need of oxygen and needs it less vitally than man. This is thought to be a factor in woman's greater capacity to endure heat, especially the heat of rooms of high temperature, as is seen in bakeries and in the manufacture of charcoal, where it is said that women are little inconvenienced by a temperature of 300° F. This is thought, also, to be one of the reasons why women experience less discomfort than men in breathing the rarefied air of high altitudes, and why, too, that women suffer less from chloroform anesthetics, and, for want of a better explanation, it has been given as the reason why women criminals more often survive hanging than men. During the Middle Ages, when the hanging of women, as well as men, was a common diversion, many gruesome stories were told of how that drivers, after a heavy jolt of the wagon, were horrified to find the recently executed woman whose corpse they were carrying suddenly arouse and sit up by their side, or how that funeral parties were surprised to find their corpse rise in their midst, or how that certain surgeons, to whom the bodies were turned over for anatomical purposes, were noted for their power to bring such persons back to life. In 1264 Henry III pardoned one Tiretta de Balsam because she survived hanging. Another woman, who was revived by Sir William Petty, lived for fifteen years after and married in the meantime. These two cases are on record and are well authenticated.

Degenerative changes in the blood vessels and rigidity of the thorax, both characteristics of senility, are found much earlier in man than in woman. Man dies suddenly much oftener than woman. Men suffer from baldness much more frequently than women. This is not confined to civilized races, but is found among savages and semi-civilized tribes, as in many of the tribes of the North American Indians, even where it is the custom for the women, instead of the men, to wear their hair short.

The greater tendency of males to both physical and psychic variations from the normal has been taken as an indication of their less staple character. Without enumerating the long list of well-known abnormalities and malformations, as clubfoot, harelip, cleft palate, supernumerary digits and nipples, common in both sexes, suffice it to say that, with the exception of congenital dislocation of the hip and a few other minor malformations, such variations are much more frequent in males than in females. The same rule holds good in regard to psychic variations. If geniuses, including musical and mathematical prodigies, are more frequent among men, idiocy and cranks are less frequent among women.

A noted English statistician has calculated that of two children, a boy and a girl, born on the same day, the boy will have only 17 chances against 11 of living one year, while the girl will have 21 chances against 11. From 5 to 15 there appears to be but little difference, but from 15 to 19, the critical period in the life of the female, the boy will have 269 chances and the girl 277 chances of living against one of death. This advantage in favor of the female increases, especially from 35 to 75, when the ratio drops slightly till after 80, when the man will have only three chances of life against one of death, while the woman's chances will be much greater.

The report of the United States Census Bureau on the vital statistics of this country for the year 1890 shows that for every five-year period from birth up to 70 years of age the death rate is much greater among males than among females. From 70 to 80 the death rate is about equal between the sexes, but from 80 to 90 there are about five women living to four men; from 90 to 100 there are two women to one man, and after 100 the proportion of women is still much greater.

The fact that woman lives a more protected life, avoids the stresses and strains that favor senility, may be a factor, but it can hardly be the only factor in her superior tenacity of life. She lives a more protected life than man because she is differently constituted. If a thousand ablebodied men and a thousand ablebodied women be uniformed, armed, and equipped for battle and ordered on a long and weary march to the front, more men would probably reach their destination, while more women would be found exhausted but more men found dead on the roadside. Owing to their peculiar psychophysical organization, women heed the warnings of fatigue and avoid the fatal crash, while man, with his iron will, after complete exhaustion resolves to take another step if he dies in the attempt.

So, after making all due allowances for the greater mortality of man in war and from accidents from dangerous occupations and from masculine excesses there are good reasons for believing that nothing short of a constitutional difference can account for the greater tenacity of life in women. Woman is a physiological miser, she accumulates energy without expending it, while man is a physiological prodigal, he expends more energy than he accumulates.

THE SEGREGATION AND EDUCATION OF CHILDREN AFFECTED WITH RINGWORM OF THE SCALP.*

By UDO J. WILE, M.D.,

NEW YORK.

The occurrence of ringworm in school children is a subject of both medical and civic importance. A decade or two ago the health of children attending the public schools was deemed a thing apart from their education, and save for compulsory vaccination but little attention was paid to the general welfare and health of this relatively large part of our

*Read before New York County Medical Society, March 27, 1911, and before the Hunterian Medical Society, New York.

community as a class. With the tremendous tide of immigration of late years and the realization of the important relation between child hygiene and the usefulness of these children as future citizens, the health of those attending our schools has assumed a greater importance in the public eye, so that at the present time we have a fairly rigid supervision maintained by a separate department of our city Board of Health acting in cooperation with the Board of Education. It is perhaps not too much to say that in no other city is the health of the child more carefully looked after than in our own. Routine inspection by physicians of the health department, and by district nurses, compulsory vaccination, examination for eye defects, throat troubles, and bad teeth, all are carefully looked into, and as a result, child health, especially during the precarious school age, has vastly improved, and, as sound mind goes with sound body, it is presumed that the work is of a higher order and the later civic usefulness of the individual thus made more probable. In the light of these facts, it may appear strange that more rigid rules and regulations are not inforced regarding certain parasitic infections of the scalp which are to be herein discussed. This has not been due to lack of attention to the facts as they are, since numerous references in the literature pointing to conditions may be found, although I believe the matter has never yet been brought to the attention of the County Society. As far back as 1897 Fox, in a clinical lecture on ringworm and favus, says: "It seems hardly necessary to add that no child with ringworm should be allowed to attend school."

In an excellent monograph on "Contagious diseases of the scalp and skin observed in children of the public school," Dr. Jacob Sobel calls attention to the extensive occurrence of ringworm and favus and pleads for partial segregation at least of those children affected.

It might be well at this juncture to discuss briefly the diseases in question. Ringworm of the body may be left out of consideration; while it is highly contagious, it is so easily recognizable, even by the lay eye, and so readily and satisfactorily treated, that a few days suffice to eradicate it, and at worst an epidemic of it would offer no very serious problem. With ringworm of the scalp, however, we are dealing with one of the most persistent, resistant infections known in the realm of cutaneous medicine. Three main clinical forms come under consideration, microsporon infection, or small spored ringworm, large spored ringworm and favus. The two forms of ringworm disease may attack children at a very early period of life, but they tend to disappear spontaneously at puberty; adults are quite immune. Favus, on the other hand, does not disappear spontaneously and adults are not protected from infection by it. Ever since these diseases have been known, doubtless long before their etiology was understood, they have been the bane of dermatological practice. The reason for this is obvious, the infecting organism lies deep in the scalp at the very root of the hair, in fact in the case of favus and large spored ringworm, within the hair itself; how futile then are the numerous antiparasitics to cope with an infection to which they cannot by any means penetrate. It is perhaps no exaggeration to say that before the *x*-ray method of epilation was discovered no extensive case of ringworm of the scalp was entirely cured by reason of the treatment applied to it. The spontaneous disappearance of the malady at puberty, deluded and no doubt still deludes many physicians as to the efficiency of one or the other vaunted remedy. Unless complicated by pyogenic infection, neither large nor small spored ringworm injures the scalp permanently. Favus almost invariably results in scarring and permanent loss of hair. The general health of individuals infected is not affected. The clinical diagnosis of favus and small spored ringworm is as a rule not difficult; the dirty yellow scutula, mousy odor in the former, and the circumscribed round or oval patches with short broken off lusterless hairs in the latter, make their recognition easy. Atypical cases of either are always difficult of diagnosis. The larger spored ringworm is much more difficult of correct diagnosis, it is not unlike seborrhea of the scalp, and too often is mistaken for dandruff. Be it remarked here that the latter is by far the most common form of ringworm found in our city. The microscopic diagnosis of all three forms is simple always. Too much emphasis cannot be placed upon the extreme difficulty of recognition without microscopic aid of large spored ringworm; only frequent association with the disease and an expert eye can be relied upon to recognize it early or when but minute areas of the scalp are affected.

The early methods of treatment with various antiparasiticides were well-nigh useless, unless they aimed at epilation of the infected hairs; no ointment, no matter how potent, can reach minute spores situated at the base of a hair follicle. The treatment by forcible epilation gave a greater measure of satisfaction; the great pain attendant, however, and its utter unfeasibility when larger areas are infected render it a method not capable of general application. Cases thus and otherwise treated in past times lasted months and years, and the infected individual traveled from one doctor to another, until the last, with the kind assistance of nature at time of puberty, affected the permanent cure. With the use of the *x*-ray, however, as an epilating agent, any case of ringworm can be cured in from three to four months. The treatment consists in exposing the infected area, using a carefully regulated dosage. Sabourand of Paris has perfected his technic to such an extent that he is able to epilate any given area in one exposure. Children thus treated are soon entirely bald in the exposed areas, and with proper stimulation the hair soon grows back in healthy condition. The *x*-ray then is the method of choice in treating these infections, not because of any antiparasitic action it may have, but simply as a convenient means of epilating, ridding the scalp of parasite, hair and all.

Ringworm of the scalp together with favus are common and ever-increasing affections in the children of our schools. Statistics as to their occurrences are absolutely unreliable, inasmuch as under the present system only the obvious cases are recognized. In the report of the Health Department, issued in 1908, the examination of the school children of the Greater City revealed 5,958 cases of ringworm of the body and head, which are grouped together without any attempt at separation. Equally unreliable as indicating the incidence of ringworm in the schools are statistics taken from the various clinics, for in the first place the cases seen there are the obvious ones and represent only a proportion of the total number, and, secondly, a fairly large number of the cases consult private physicians and do not come into the dispensary records. Remembering these facts, however, the following statistics are

nevertheless interesting if not valuable. Of 490 children who consulted the Beth Israel Hospital Dispensary during 1910, 168 were attending school; of this number 16, or almost 10 per cent., had ringworm or favus of the scalp. At the New York Skin and Cancer Hospital in the service of Dr. George Henry Fox during 1910 there were 31 cases of ringworm and favus, out of a total of 301 children attending school, or a percentage of over 10. These are but two of over fifty dispensaries which treat such cases. Remembering then that a large number of early and difficult cases escape recognition, are not the statistics of the Health Department of 5958 total cases of ringworm of the scalp and body together instructive and more than suggestive for more rigorous supervision of these diseases? In ringworm we are dealing with a disease of high grade contagiousness. Favus, while more dangerous, is less contagious. It goes without saying that children thus affected should not be allowed to mingle with healthy children; therefore they should be excluded from schools during the entire period of the disease. Have we a right to exclude such children from school for months or possibly years, put them on the streets at a time when early discipline and education mean so much to them, particularly our foreign-born children? Most decidedly not; the parents of these children pay taxes; if for no other reason their children must be educated on this account; but the community owes it to itself to educate them. Statistics show that a large percentage of the criminal class is recruited from the ignorant, particularly from the foreign element; the community in refusing to educate children suffering with a contagious disease which should properly exclude them from contact with healthy children places upon itself the risk of thus swelling its criminal element. We educate our blind, our deafmutes, and our cripples in separate institutions; why not our children with ringworm and favus?

The question naturally arises, Is such a scheme feasible? The answer to this is that other cities and other countries have attacked the problem with success. In England a beginning has been made by establishing a separate school for children in the various asylums. Here hundreds of children are boarded, treated, and cured in a few months by x-ray epilation method. But far ahead of London, where a start has been made, and infinitely ahead of New York, where nothing has as yet been done, is Paris, where we find a splendidly equipped institution, the École Lallier, at its head and supervising the work an eminent dermatologist, who each year treats and cures almost two thousand cases of ringworm and favus, and during the time of their treatment the children lose not a day's schooling.

What is the disposition at the present time in our schools of children affected with ringworm or favus? When detected during routine examination such children are sent home and are not received back in the school until they shall have begun treatment at the hands of a private physician or in a hospital dispensary. Once under treatment they are allowed to return and mingle with their healthy comrades. Would the establishment of separate schools where education and treatment could be combined stamp out ringworm in our city? It would not—not while the great tide of immigration continues, and new cases are brought in from Europe, but such measures would check its spread and protect the uninfected individuals. In brief, then, what measures should be adopted to correct this obvious error of omission. In the first place the work of examining children for the diseases in question should not be placed upon the already overworked medical inspector who cannot be expected to be a specialist in every field; it should be done by experts; such experts should not only be attached to the school but should be at the port of entry at the quarantine station. No child having favus or ringworm would then be admitted into the country and the letter of the present law on this subject would then be carried out.

To attack the diseases already present within the school the ideal would be the establishment of one or more graded schools where infected children could be segregated, treated, and taught at the same time, the treatment to be in the hands of experienced x-ray operators. Failing in such an elaborate scheme, there should at least be separate ringworm classes in several of the schools where at least partial segregation could be maintained and treatment carried out.

The question of expense is one not to be met or answered by us as physicians; for us it is merely to point out a much-needed reform in an otherwise excellent system of public health as it concerns the child of the public schools.

REPORT OF TWO CASES OF GASTRIC ULCER DUE TO DISEASED GALL BLADDER AND APPENDIX.

REPORT OF A CASE OF PERFORATED GASTRIC ULCER WITH UNUSUAL SYMPTOMS.

By ASPINWALL JUDD, M.D.,

NEW YORK,

ADJUNCT PROFESSOR OF SURGERY, NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

Since the attention of the medical profession was called by Mayo Robson to the coincident occurrence of gastric ulcer and disease of the gall bladder and other abdominal organs, and his inference that the etiology of gastric ulcer is frequently closely associated with these lesions, a number of similar reports have appeared in various medical journals. About two years ago a series of cases was reported from the Mayos' clinic in which the cause of gastric ulcer seemed to be a diseased appendix. The cases reported below appear peculiarly to fit in with this theory, and have seemed to me to possess sufficient interest to justify their publication.

Case I.—The first case, a young Italian woman of 25, with perfect previous family and personal history, presented herself in my service about three years ago, suffering from typical symptoms of gastric ulcer. Upon opening the abdomen, I discovered near the pylorus, but entirely outside the ring, two ulcers, one about the size of one's little finger nail, the other about one-third the area of the first. The larger one was about to rupture and was apparently the cause of the persistent hemorrhages from which she had suffered. I was enabled to excise these ulcers without narrowing the pyloric opening. The wound was closed in the usual manner. Primary union resulted and the young woman made an uneventful recovery. About fifteen months later she presented herself to me once more with a recurrence of her original symptoms, though not so marked, she having had but one hemorrhage and but little loss of flesh and strength. Objecting to further operative interference, I turned her over to Dr. Ludwig Kast. After about three weeks in the

hospital she presented such improvement that, although Dr. Kast was of the opinion that sooner or later a posterior gastroenterostomy would have to be performed, he consented, on her earnest solicitation, to allow her to go home and report at a future date if her symptoms returned. About two months ago she came to me for the third time with a return of all her previous symptoms in a somewhat augmented form. This time she was anxious for an operation, and in view of her previous history, this seemed the only solution of the problem. Upon opening the abdominal cavity, I found that the site of my original ulcers was perfectly healed. Having in mind the reports of Mayo Robson and the Mayos, I examined the gall bladder, duodenum, and surrounding structures, and found them perfectly normal. The appendix, however, I found very much swollen, congested, with a number of omental adhesions, and apparently nearly ready to rupture. This I removed. So sure was I from my history that I had to deal with another gastric ulcer, that I proceeded to a posterior gastroenterostomy. Upon opening the stomach, I found an ulcer upon the greater curvature as large as my original one. This I excised. The patient made an uninterrupted recovery. It is interesting to note in this connection that, although the patient had been examined most carefully on three different occasions, she had given no history of nor presented any symptoms of appendicitis, and physical examination had given only tenderness and some slight resistance on the right side.

Case II.—Miss B. Trained nurse. Patient had been under observation by another surgeon, suffering from an indefinite complex of symptoms including nausea, vomiting, constipation, slight jaundice, tenderness over the appendical region, considerable emaciation, and great anemia for six months. I was finally asked to operate upon her, the diagnosis resting between appendicitis and gall stones. On the morning before operation she had a large hemorrhage from the stomach. This turned our attention to gastric ulcer. The patient took ether very badly, although given by an expert, her respirations being as low as six or seven. An incision was made through the right rectus muscle with the idea of doing as much work as possible through a single opening. An enormously dilated gall bladder with many adhesions, was found. After separating the adhesions and opening the gall bladder, a considerable amount of very viscid bile was evacuated. No stones were found, the kinking of the duct due to adhesions being the apparent cause of obstruction. Upon the anterior stomach wall, near the pylorus, was discovered an ulcer. Following out the line of thought suggested by the Mayos, Mayo Robson, and others, no gastroenterostomy was thought necessary. The patient made an uninterrupted recovery, and at the present time, two months later, has had no return of symptoms. An observation made by my anesthetist, Dr. Byron T. Davey, is worthy of note. Immediately upon opening the gall bladder and relieving the tension, the patient's respiration became normal and for the remainder of the operation she took her ether perfectly.

The third case upon my list is by far the most interesting.

Case III.—This patient, a woman about 45 years of age, was sent in to my service by a physician who had had her under observation for about ten days. During this time she had run a temperature, higher at night, varying from 99° to 103°. Her pulse had likewise varied from 90 to 110. She had had no nausea or vomiting, had eaten solid food up to the time of her admission to the hospital, complained of no symptoms beyond general malaise, except for considerable tenderness over the appendical region. Her bowels were constipated. The diagnosis of appendicitis was made. It seemed to me that I could palpate a mass in the region of the appendix. My diagnosis was a subsiding appendicitis. I therefore placed an ice coil upon the abdomen, put the patient upon a liquid diet, and awaited results. On the third day after admission to the hospital her pulse became rapid and thready, her facies somewhat pinched, and as her temperature was rising, I concluded to operate immediately. Upon opening the abdominal cavity, I found it full of free blood and old and organized blood clots. A superficial examination failed to discover the site of the hemorrhage, and it became necessary to make a wide incision, turn out the blood clots rapidly, and after searching each portion of the abdominal cavity, to pack with dry towels, going from section to section in order to clear the field of blood. The appendix was found massed down with omentum in a diseased condition, and was removed. Upon reaching the stomach, I found a large ulcer upon the lesser curvature near the pylorus, perforated, from the artery of which was occurring very rapid hemorrhage. The woman was so exsanguinated that her tissues were translucent. I therefore merely purse-stringed the ulcer, which served the double purpose of stopping the hemorrhage and closing the ulcer, and sewed her up rapidly with a through-and-through suture in the autopsy method, hoping to get her off the table before she ceased breathing. It seemed as though almost all her blood had been extravasated into her abdomen. We immediately bandaged off her arms and legs while she was still upon the operating table, and infused her with 1400 c.c. of normal saline solution, to which I had added two drachms of 1 to 1,000 adrenalin solution. After remaining in extreme shock for 48 hours the patient went on to an uninterrupted recovery with primary union. The points of interest in this case, it seems to me, are: First, the seeming confirmation of the theory already adduced that appendicitis can be a cause of gastric ulcer; and the fact that a perforated gastric ulcer, with enormous hemorrhage, could go on with so few apparent diagnostic symptoms. That the hemorrhage was of long standing seemed to be proved by the old and organized blood clots. The woman did not present at any time before the opening of the abdomen the picture of shock or hemorrhage that is ordinarily presented to us. It would also be observed that she had never had any hemorrhage by mouth, and that she had taken solid food for the first ten days without complaint of pain or other symptoms usually referable to ulcer.

137 West Sixty-ninth Street.

Prophylaxis Against Syphilis.—F. P. Guiard considers the practical methods of prophylaxis against syphilis. After a suspected coitus, friction with the calomel pomade of Metchnikoff gives only a relative guarantee of immunity, since it does not prevent extragenital infection and influences only the superficial parts of the organ. A simple inunction preceding coitus appears to the author to be much more practical, since the infectious microbes, before reaching their destination, must pass through a thick coating of pomade. This inunction renders traumatic excoriations much less likely, and envelops them with a protective barrier which is effective against the pathogenic organisms. Neither inunction nor friction can be regarded as an infallible preventive against contagion. Still they act as a great protection against the microorganisms. The author advocates the systematic use of such protectives against syphilis.—*Journal de Médecine de Paris.*

A DEPARTMENT OF PUBLIC HEALTH.

SENATOR Owen has lost no time in reintroducing his bill to establish a Department of Health, the bill being No. 1 on the calendar of the Senate of the Sixty-second Congress. The bill differs in some particulars from the one in the previous Congress, most of the features which were objected to by the anti-medical opponents of the measure having been so modified as to disarm honest criticism. It expressly disclaims granting any authority to the Department of Health "to exercise or to attempt to exercise, without express invitation from the chief executive or other proper authority of the State, any function belonging exclusively to such State, or to enter any premises in any State without the consent of the owner or occupant thereof." It also provides that "the Department of Health shall recognize no so-called school or system of medicine."

In its general features the bill is highly commendable. It unifies the sanitary forces of the Government by bringing together under one head many of the bureaus now scattered through the several departments: the Public Health and Marine-Hospital Service of the Treasury Department, the Bureau of Chemistry (in its relation to the pure food and drug law) of the Agricultural Department, and the Division of Vital Statistics of the Bureau of the Census of the Department of Commerce and Labor, but not the Bureau of Animal Diseases of the Agricultural Department. Whether the latter should be included in the Department of Health is a matter for discussion. Many of the animal diseases are communicable to man, and as such their investigation should seemingly be under the control of the Department of Health; yet they are perhaps chiefly important in their economic relations, and as such might more properly be within the province of the Department of Agriculture. The question may be wisely left, as Senator Owen's bill leaves it, to be decided later, after the new Department has been created and is in good running order; the bill provides for the future transfer by the President of any bureaus from other Departments engaged in work pertaining to the public health. The bill also provides for the establishment within the Department of Health of Bureaus of Sanitary Research, Child Hygiene, Vital Statistics and Publications, Foods and Drugs, Quarantine, Sanitary Engineering, Government Hospitals, and Personnel and Accounts.

There are, however, two serious defects in the bill which make the desirability of its passage very questionable. It creates a Department of Health, but places at its head a "Director," not a "Secretary." That, of course, means that the head of the Department will not have a seat in the Cabinet, and that the Department will therefore be a nondescript, something between a Bureau and a Department, a little above the former in that it will be in a measure independent, but inferior in dignity to the latter. The science of sanitation is, to speak modestly, as important as that of farming or of labor and trade, and it should have equal recognition. To create a Department of Health and exclude its head from the President's official family would be an indignity which the medical profession of the country would very properly resent. The public would not be slow to see the significance of such discrimination officially placing the status of the physician below that of the merchant, the laboring man, and the farmer, and the new Department would command little respect.

Another objectionable feature is that the bill does not provide that the Director of the Department of Health shall be a physician, or even a sanitarian. It specifies that the *assistant* to the Director "shall be a skilled sanitarian"; in other words, he is to do the work, while any old politician can "boss the job." That a medical man shall *not* be at the head of the Department is evidently the intention of those at the back of the bill. The March Bulletin of the Committee of One Hundred on National Health devotes a large part of its space to a criticism by ex-President Eliot of Harvard College of the Mann bill in the Sixty-first Congress. He is quoted as saying: "I am sure it is not desirable that the national public health service should be placed in the hands of the Surgeon-General and his subordinates.....Over any Bureau or Department with such functions a civilian scientist ought certainly to preside.....We have never had a Surgeon-General who was fit to exercise such a comprehensive control, and it is in the highest degree improbable that we ever shall have, since the training and functions of a Surgeon-General do not prepare him for that kind of scientific work.....The bill makes an unwise proposal in an insidious way. It ought not to get any standing at all before Congress." Ex-President Eliot has, of course, as much right to his opinion on that subject as any medical man has to his own concerning the composition of a five-foot shelf of books—and no more. But the featuring of his opinion in the Bulletin shows what the supporters of the Owen bill hope from the Department of Health.

If the Director of a Department of Health is to be a lawyer, or a statistician, or a labor agitator, or any one but a skilled sanitarian with a medical education, it will be better to consolidate the several bureaus above mentioned with the Public Health Service and continue that as a Bureau of the Treasury Department. The medical profession of the country does not want a Department of Health whose head shall be a layman locked out from the President's Council Chamber. If there is no medical man in the country able to conduct such a Depart-

ment and worthy to be a member of the Cabinet, then we had better be content with the efficient Bureau of Public Health that we already have.

SANITARY CONDITIONS IN ALASKA.

The insanitary conditions prevailing in the native villages in Alaska has for a long time been a subject of grave concern to the Bureau of Education, of the Department of the Interior. Every report received from the officers of this service, as well as from medical officers of the Army and of the Public Health and Marine-Hospital Service who have had opportunities to observe the prevailing conditions, has spoken of the inroads of syphilis, trachoma, and tuberculosis. According to a report made to the Surgeon-General of the Public Health and Marine-Hospital Service by Assistant Surgeon Hazeltine, published in the Public Health Bulletin of May 5, the ravages of tuberculosis affect fully one-third of the native population of southern Alaska. In the southeastern portion of the country the population consists of Indians having little, if any, admixture of white blood. They live in miserable frame huts, built without paper or plaster, and placed in rows along the beach. The houses are so close together that proper lighting or ventilation is impossible. Some of the houses are built to accommodate from four to six families, but even in this event there is only one room, each family occupying a certain allotted space. In one such room, 30 x 30 x 8 feet, Hazeltine counted thirty-four people, several of whom were evidently suffering from active tuberculosis. Very much the same conditions prevail among the half-breed tribes of the southeastern portion, the housing conditions being, if anything, worse.

Among all the natives of southern Alaska the most horrible conditions of filth are prevalent. Sexual morality is on a low scale and venereal disease is common. Trachoma is favored by the unhygienic surroundings and defective vision is widespread as a result of this disease. The average native has great faith in the curative properties of medicines, but seems to fail entirely to understand the value of prophylactic measures. If an effort is made to get them to clean up their villages they will conceal the filth, thinking it sufficiently well disposed of if it is dumped on the ground under the floor of their houses.

An interesting exception to this general rule of bad sanitation and resulting ill health is found among the Indians of the village of Metlakatla. Under the guidance of Rev. Wm. Duncan these villagers have acquired a considerable degree of civilization. They have sanitary houses and are much more free from tuberculosis. Hazeltine attributes this comparative freedom entirely to their better mode of living. It is possible, however, that another factor may enter into this comparative immunity. These Metlakatla villagers are not, strictly speaking, natives of Alaska, but represent an immigration from British Columbia in 1886, and it is not impossible that long years of contact with the white man in Canada had already tended to weed out the tuberculous diathesis by a process of natural selection or survival of the fittest.

However, the villagers of Metlakatla represent but an insignificant portion of the native population, and it would seem that the time is now ripe for an active sanitary campaign if we are to preserve the main body of the population from extermination by infectious diseases. The laws of Alaska are almost entirely lacking in provisions that aim to preserve the public health, and, therefore, acting on the request of the Department of the Interior, a surgeon of the Public Health and Marine-Hospital Service has been detailed for duty in Alaska under the direction of the Commissioner of Education. He will supervise all measures relative to the medical and surgical relief of the natives of southern Alaska, inaugurate measures for the sanitary improvement of their surroundings, and report the results of his observations with a view toward obtaining legislation to enable the work to be prosecuted on an adequate scale.

THE COLICKY PAINS OF APPENDICITIS.

In the course of an article on the use of local anesthesia in operations for appendicitis (*Deutsche Zeitschrift für Chirurgie*, 109 Band, Heft 1 and 2) Friedrich Hesse relates a number of interesting observations which go far in explaining the symptomatology of appendicitis, so far as the subjective sensation of pain in that disease is concerned. The usual picture of acute appendicitis, with the early general abdominal pains of colicky nature, followed by a gradual localization of pain and tenderness in the epigastrium and about the umbilicus, and, finally, approximately over the appendix in the right iliac region, is well known. Hesse found that if for any reason the analgesia of the abdominal parietes or of the parietal peritoneum was not perfect at the time of operation pain at the site of incision or a sensation of pulling, dragging, or otherwise disturbing these structures was felt. This pain, of course, had nothing to do with the early symptoms of appendicitis. It was quite different, however, when the deeper structures were reached. The intestines themselves, including the appendix, were quite insensitive; any pulling upon the mesocecum or mesappendix, however, was instantly followed by marked subjective sensations of various nature, from an unpleasant sense of pressure to colicky pain felt, not at the site of insult, but between the xiphoid cartilage and the umbilicus. This pain was declared by the patients to be similar to the initial pain of appendicitis, being felt, not upon the surface of the skin, but deep in the abdomen. Same sensation was caused by any pulling upon the great omentum in the neighborhood of the appendicular region. The pain ceased of its own accord after a certain time, though the mesocolon or the mesappendix was still on the stretch; yet any new manipulations of these structures involving change in their tension resulted in renewing the pain felt in the upper abdominal region. It is to be remembered, moreover, that this pain was in no wise a radiation from the seat of injury, for this remained without local sensation so long as the parietal peritoneum was not injured.

Hesse applies these facts in the following manner to the explanation of appendicular pain. The initial pain occurring with the onset of appendicitis and felt in the epigastric and umbilical regions he refers to the change in the tension of the mesappendix caused by the swelling of the organ, the slight change in its position, and finally the beginning infiltration of the surrounding structures. The disappearance of this pain may be due to the adaptation of the nervous system to the new degree of tension in the mesappendix, or to the appearance of more severe pains in the ileocecal region, which overshadow the others. These later pains are the result of the irritation of the neighboring parietal peritoneum, the portion of the structure that proved so sensitive in Hesse's operations under local anesthesia. These pains continue for a more or less prolonged period, depending upon the local pathological conditions in the region of the appendix.

Hesse's material embraced 82 cases of appendicitis operated upon under local anesthesia. The results of his inquiries were so uniform, when subjective differences were allowed for, that he has no hesitation in putting forth the above explanation of the initial general pains and the later local pain of appendicitis.

WOMAN AND LABOR.

The position of woman under modern conditions has so greatly changed that it is arousing a considerable amount of anxiety in all civilized countries. This is manifested by the unrest among women exemplified by the suffrage movement. Olive Schreiner, the well known author of "The Story of South African Farms," after a long spell of rest from the making of books, has just given to the world a work entitled "Woman and Labor," in which she sets forth in her own expressive and convincing language certain views as to the modern women's movement. Her argument is somewhat in this wise, that woman is losing her old place in the scheme of existence, her ancient fields of toil are slipping from her, and if new fields are not opened to her she must sink into a state of sexual parasitism. By so doing she must necessarily degenerate and with her degeneration will come also the degeneration of the males.

In the history of the world woman has degenerated before to a state of sexual parasitism. In the days of the decadence of Rome and Greece this was the case, as also in France in the eighteenth century before the revolution. But Olive Schreiner thinks that the situation is now more ominous than ever before. In former times it has wrought the ruin only of the ruling classes, but at the present time it threatens all classes. The advance of civilization has contracted woman's sphere of labor. Machinery has taken the place of manual labor to such an extent that domestic duties are reduced to a minimum. Moreover, child bearing is not now considered woman's first duty; indeed, as Olive Schreiner points out, "the lowered death rate, the rarity of war and pestilence are rapidly bringing us to that day when child bearing shall be regarded as a lofty privilege, permissible only to those who have shown their power to rear and provide for their offspring." Of course so able a woman as the South African writer does not demand that the wheels of time shall be put back and that woman shall again resume her old domestic duties, shall again be regarded in the first instance as a child bearer, or even as a child trainer, for she well recognizes that conditions have so altered as to render this impossible. She demands for woman in this new world that she shall have her share of honored and socially useful human toil, her full half of the labor of the children of woman. The question of woman and labor is of the first importance, in fact it is possibly the most vitally important problem bearing upon the welfare and health of the race of this day. It is well that women like Olive Schreiner should study the matter and write upon it, but it would be better still if she and her compeers would give some really practical advice on the subject.

THE MICROORGANISM OF TYPHUS FEVER.

Another of the infectious diseases is yielding up its secrets to the persistence of the investigator. The infectious agent of typhus fever has been proved to exist in the blood of patients suffering from the disease, the virus has been transmitted through long series of monkeys, and the *Pediculus vestimentorum* has been demonstrated to be the chief if not the only agent whereby the infection is carried from one individual to another. The ultimate cause, however, has proved very elusive.

Predjetschensky (*Centralblatt für Bakterienkunde*, etc., 1 Abt., Bd. 55, Heft 3) describes an organism which he has succeeded in isolating from the blood of these patients. He was able to obtain pure cultures only by inoculating 200 c.c. of bouillon with from 2 to 5 c.c. of blood, drawn between the sixth and ninth days of the disease. It is described as a short, fairly thick bacillus with rounded ends, occurring singly or in chains. It is actively motile and is not stained with Gram. Bouillon is uniformly clouded with the formation of a grayish precipitate. Milk is coagulated in 3 or 4 days, gelatin is not liquefied. On slant-agar it develops as an elevated growth with a glistening grayish-white film, the water of condensation being changed into a cloudy, gummy mass. On potato it forms a thick dull-gray film which later becomes brownish, without the presence of gas bubbles. In dextrose bouillon it forms no gas but does produce acid. It does not form indol. On the Conradi-Drigalski medium there are produced raised blue colonies which after three days are surrounded by a rose color; on Padlewsky medium with malachite green, golden yellow colonies from which begin to show a green tinge in three or four days.

The organism was agglutinated by the serum of typhus patients in a dilution of 1-10 in 1 hour, and of 1-40 in 4 hours, while controls with the serum of persons in health or suffering from other diseases showed no agglutination. Mice, dogs, and guinea-pigs inoculated with a pure culture developed a fever and died, and the bacillus was recov-

ered from their organs. The author was able also to cultivate this organism from the sputum of his patients and he thinks that its presence here may be the chief factor in the spread of the disease. This bacillus is, apparently, not unlike the one which Ricketts and Walker found in stained blood smears and which, in their opinion, belonged to the hemorrhagic septicemia group.

Therapeutic Use of Radium.

The *Dominion Medical Monthly*, March, 1911, contains an article by W. H. B. Aikins and F. C. Harrison, Toronto, on the use of radium, and particularly with regard to their experience in its employment. Perhaps the most instructive part of this paper is that which refers to post-operative prophylaxis. It is pointed out that Louis Wickham of Paris, in his most recent publications, insists strongly on the association of radium with surgery. He claims that in many instances the radium rays will turn an inoperable case into an operable one, and that after operation for malignant disease, when, no matter how extensive the dissection, one can never be sure of having removed all the cancerous tissues, radium should be used over the scar and area of operation, as a prophylactic measure in order to destroy any stray neoplastic cells. Aikins and Harrison state than in three cases they have applied treatment in this manner, two of the cases being sarcomas and the other a carcinoma. In one of the sarcoma cases, a man 61 years of age was operated on in May, 1908. A very extensive dissection was done in London, England, in August, 1910, and six days after this operation the patient went to Paris, where radium applications were made by Wickham for a period extending over three weeks. In October, 1910, he was given in Toronto another thorough radiation over the field of operation, and particularly at points where the scar tissue was in excess. Aikins and Harrison appear to take the view held by Wickham, that it is unwise to claim too much for the therapeutic properties of radium. That it is valuable in certain forms of malignant and other diseases is known, and it is especially of use as an adjunct to the knife. Radium therapy is scarcely yet out of its swaddling clothes, but judging from the experience of Abbe, Wickham, Dawson Turner, the authors just mentioned, and other authorities, the element will prove to be a precious addition to the physician's and surgeon's armentarium.

Mendel's Laws Applied to Wheat Breeding.

The laws enunciated by the wonderful Austrian abbé some thirty years or more ago are only now coming into their own. That is to say that it is within the past ten years that earnest endeavors have been made to put his theories into practice. In the case of plants the efforts have been attended by a considerable amount of success. In fact, the laws as regards plants are fairly definite and the outcome of breeding upon Mendelian lines affords hope of ultimate success. Professor Biffen delivered recently a lecture on Mendel's laws applied to stock and plants (*Medical Press and Circular*, April 12). He showed that some improvement had occurred in stock and plants by breeding for the qualities desired during the past ten years by following those laws. In the case of live stock breeding no conspicuous success could be chronicled, but the application of the laws to this kind of breeding is as yet only in the indefinite stage. So far as wheat and certain other plants are concerned, it is passing from the experimental to a state of established routine. Nevertheless, even to the man of science, who alone is able to cope with the situation, the work is beset with endless difficulties. According to Biffen, encouraging success has been met with in raising new varieties of wheat and the putting of the theory into practice in this respect promises to lead to important economic developments, not only as regards wheat, but in the breeding of plants generally and farm animals. Despite the enthusiasm of eugenists and the disciples of Mendel, the day is yet far distant when men will be bred in a similar manner. However, the outlook for an improvement of the civilized races mentally and physically is hopeful if only from the fact that the matter is arousing the attention of scientific and ordinary individuals alike. A study of Mendel's laws is, at any rate, in the direction of progress.

News of the Week.

High Mortality Record.—During the month of March, 1911, there were 14,227 deaths in the State of New York, of which 8,353 occurred in New York City alone. The high mortality is largely due to the prevalence of influenza, which caused over 40,000 deaths during the first three months of the year. During the same time the total number of births in the State was 18,693, an excess over the number of deaths of 4,366. It is interesting to note that while in New York City the births outnumbered the deaths by 4,617, in all the remainder of the State the deaths outnumbered the births by 157. In the rural districts alone there was an excess of 470 deaths over births.

British Census Returns.—The early returns of the recent British census indicate that the population of the United Kingdom has very nearly doubled since 1831. The death rate for 1911 is given as 13.9 per thousand, and the birth rate as 24.7.

Cholera in St. Petersburg.—Since the recurrence of the cholera epidemic in Russia forty-one suspected cases of the disease have been reported in St. Petersburg.

Hospitals and Private Practice.—The suggestion that instructors in medical schools who are also hospital attendants should be restricted as regards their private practice has been made at the Johns Hopkins Hospital and has provoked considerable discussion. Whether such a policy would meet with the approval of those members of the hospital staff whose connection with the hospital has been mutually beneficial, and who in many cases have large and lucrative private practices, remains to be seen. It is proposed that such men shall be given much larger salaries than at present with the understanding that they devote their entire time to teaching, hospital work, and research in medicine. This would place the clinicians upon the same standing as the laboratory men, the majority of whom are barred from practice already. That it would increase the efficiency of the hospital men seems doubtful, since the Johns Hopkins Hospital staff now includes many noted names.

Prize for New Writing Forms.—A preliminary announcement has been made of the offer of a prize of one thousand marks by Prof. Dr. Theodor Jaensch of Berlin for the solution of the

following problem: To establish by comprehensive and detailed physiological experiments what basic principles are necessary for the production of a rapid and legible writing, especially print, and which forms of writing commonly employed at the present time best fulfil the conditions. Further details as to the terms of the competition will be given later, though it is planned that it shall be as free as possible from any preliminary conditions. It is suggested that an entirely new form of writing would not be undesirable, and that the matter of print versus direct picture writing or word signs should be considered.

Sloane Hospital for Women.—On July 1, 1911, there will occur two vacancies on the Resident Staff of the Gynecological Division of the Sloane Hospital for Women, New York: 1. The position of Resident Gynecologist, with a service of two years and a salary of $1,500 a year. 2. The position of Junior Gynecologist, with a service of one year and a salary of $500 a year. Applications may be made in person to Dr. Edwin B. Cragin, 10 West 50th street, New York.

Decision Against Osteopaths.—The Apellate Division of the Supreme Court in Brooklyn, N. Y., on May 12 affirmed the judgment of Justice Putnam in refusing to grant a mandamus to Charles S. Bandel, an osteopath, to compel the recognition by the Board of Health of a death certificate signed by an osteopath. It is possible that the case, which has excited much interest throughout the State, may now be carried to the Court of Appeals.

Euthanasia Again.—Speaking in Boston on the subject of eugenics before a convention of Unitarian ministers, the Rev. George W. Cutter is said to have suggested the elimination of degenerates by the use of anesthetics, on the plea that many of the inhabitants of State institutions would be better dead than alive. He also advocated the physical examination of applicants for marriage licenses, and the approval of boards of health before such licenses are issued.

Police and First Aid.—The members of the police force of Seattle, Wash., are now supplied with outfits for giving first aid to sufferers from accident or sudden illness. Each patrolman carries an emergency or first-aid dressing packet containing a tourniquet, bandages, and other simple appliances together with written instructions.

Dr. Albert M. Somers of the St. Lawrence State Hospital, Ogdensburg, N. Y., has been appointed medical inspector for the State Lunacy Commission in place of Dr. Doran, who was recently made superintendent of the Long Island State Hospital.

University of Pennsylvania.—Dr. Richard M. Pearce has been transferred from the Chair of Pathology to that of Experimental Pathology, and Dr. Allen J. Smith has been transferred from the Chair of Tropical Diseases to that of Pathology, formerly occupied by him. Dr. George Ross and Dr. A. D. Whiting have been appointed instructors of surgery in the service of Dr. John B. Deaver.

Hookworm in Jamaica.—Throughout large districts of the island of Jamaica hookworm disease has been found to be prevalent, and a medical investigation is being made. A large proportion of the convicts in the penitentiary are said to be affected.

Cartoon Contest.—The American Medical Association, for the purpose of stimulating interest in medical matters in connection with the annual meeting at Los Angeles during June, has offered a cash prize of $200 for the best series of six cartoons dealing with any one or all of the following health problems: (a) Insects in the Causation of Diseases.—Literature to consult: United States Department of Agriculture, Bureau of Entomology, L. O. Howard, Chief; circulars of any of the leading municipal or State Boards of Health. (b) Beneficent Effects of Vivisection.—Literature to consult: *Ladies' Home Journal*, April, 1910, page 21; *Harper's Weekly*, June 25, 1910, page 5; *Science*, December 2, 1910, and February 26, 1909; series of pamphlets issued by American Medical Association on Protection of Medical Research, I. to XX., furnished on request. (c) Pure Food and Adulterated or Contaminated Foodstuffs.—Literature to consult: United States Department of Agriculture, Bureau of Chemistry. Ask for notices of judgment for 1909 and 1910. Pamphlets and reprints on food adulteration, published by American Medical Association, furnished on request. Notice of intention to participate in the contest should be sent to Dr. Frank B. Wynn, Director of the Scientific Exhibit, 31 Newton Claypool Building, Indianapolis, Ind., from whom further details may be obtained.

Gifts to Charities.—By the will of the late Samuel Hall of New York the Presbyterian Hospital in this city receives a bequest of $1,000.

The New York Orthopedic Dispensary and Hospital receives a cash bequest of $5,000 by the will of the late Oscar Egerton Schmidt of New York, and also the residue of the estate, the value of which is not given.

Mount Sinai Hospital and the Montefiore Home for Chronic Invalids receive bequests of $5,000 each, and the Beth Israel Hospital one of $1,000 by the will of the late Martin Herman of New York.

By the will of the late Nils Poulson of Brooklyn the Bay Ridge Hospital and Training School for Nurses and St. John's Guild receive $1,000 each.

The Hospital for the Ruptured and Crippled of New York receives $2,000, and the Free Church Home for Incurables $8,000 by the will of the late George H. Morgan of New York. A part of the latter bequest is to be used in endowing a free memorial bed, and the remainder in providing entertainment for the inmates on holidays.

By the will of the late Mary F. Bennett of St. David's, Pa., the sum of $5,000 each is bequeathed to the Philadelphia Home for Incurables, to the Presbyterian Home for Widows and Single Women, and to the Home of the Merciful Saviour for Crippled Children. The sum of $10,000 is also left to two sisters in trust, to be used on their deaths for the establishment of free beds in hospitals to be selected by the executors.

The American Association for the Conservation of Vision was incorporated in New York on May 13 to study and investigate conditions and causes which result in blindness and impaired vision, and the relation of eye strain to physical and mental health and to human efficiency, and to devise means to prevent blindness.

Beth Israel Enlarged.—The Beth Israel Hospital, New York, has again increased its capacity by the opening of another ward accommodating thirty patients. It will be used for male medical cases. The ward opens on a roof garden for convalescent patients and others requiring outdoor treatment.

New Peoria Hospital.—The cornerstone of the

new hospital in Peoria, Ill., was laid on May 3 by President Harris of the Northwestern University. The building, which it is estimated will cost about $200,000, will when completed be under the charge of the Methodist Episcopal Deaconesses.

Sanitary Object Lessons.—The formal inauguration of the new department of public health established in connection with the American Museum of Natural History, New York, was announced for Monday, May 15. It was expected that addresses would be delivered by Mayor Gaynor, Dr. George A. Soper, Dr. C. E. A. Winslow, and Dr. Harvey W. Wiley. The exhibition will include apparatus, models, and charts, illustrating the work of the Metropolitan Sewerage Commission, of which Dr. Soper is president.

The Academy of Medicine of Northern New Jersey was recently incorporated in Newark. The officers of the new organization, which contains about three hundred members, are as follows: *President*, Dr. Edward J. Ill of Newark; *Vice-Presidents*, Dr. Thomas N. Gray of East Orange, and Dr. Wells P. Eagleton of Newark; *Secretary*, Dr. Julius Levy of Newark; *Treasurer*, Dr. Henry J. F. Wall of Newark.

The American Surgical Association will hold its thirty-second annual meeting at Denver, Col., June 19, 20, and 21.

The Medical Library Association.—The 14th annual meeting of this association was held May 9 and 10, 1911, at the Marlborough-Blenheim Hotel, Atlantic City. The first session was held Tuesday evening and the following program was carried out: President's address, by Dr. J. H. Musser, Philadelphia, Pa.; papers, "Hospital Records in Relation to the Hospital Librarian," by Mrs. Grace W. Myers, Boston, Mass.; "The Establishment of Medical Libraries in County Medical Societies," by Dr. Carl Black, Jacksonville, Ill.; "The Changes in Medical Periodical Literature Since January, 1909," by Mr. C. Perry Fisher, Philadelphia. The second session was held the morning of May 10. At this meeting the reports of the various committees were read and the election of officers took place.

Physicians and Pharmacists to Discuss the Prescription.—There will be a joint meeting of the Medical Society of the County of New York and the New York Branch of the American Pharmaceutical Association at the New York Academy of Medicine on the evening of May 25 at 8:30 o'clock. The purpose of the meeting will be to discuss "The Prescription." The following papers will be read: Dr. James J. Walsh, "Some Curiosities in Prescriptions"; Dr. Egbert Lefevre, "The Prescription from the Physician's Point of View"; Prof. Joseph P. Remington, "Some Interesting Prescriptions"; Mr. Jacob Diner, "Efficient Medicaments in Palatable Form"; Dr. George C. Dickman, "The Ethical Consideration of the Prescription." A general discussion will follow the reading of the papers.

Obituary Notes.—Dr. Lester A. Elster of Alameda, Cal., a graduate of the Bellevue Hospital Medical College in 1867, died at his home on May 1, aged 68 years.

Dr. T. C. Longino of Atlanta, Ga., a graduate of the Southern Medical College, Atlanta, in 1895, died at his home on April 28, aged 37 years.

Dr. William A. Trueblood, formerly of Ottumwa, Ia., a graduate of the Medical Department of Washington University, St. Louis, in 1903, and a member of the Iowa State and Wapello County Medical Societies, died at his home in Baker City, Ore., on May 1, aged 34 years.

Dr. Isaac N. Danforth of Chicago, Ill., a graduate of the Dartmouth Medical School, Hanover, N. H., in 1861, a member of the American Medical Association and the Illinois State and Cook County Medical Societies, consulting physician to the Mary Thompson Hospital and to St. Luke's Hospital, formerly pathologist to the Cook County Hospital, and professor of pathology and clinical medicine in the Chicago Medical College, died at his home on May 5, aged 75 years.

Dr. Samuel E. Holtzman, formerly of Pontiac, Ill., a graduate of the New York University Medical College in 1862, died suddenly at his home in Ocean Grove, N. J., on May 8, aged 73 years.

Dr. Albert H. Bill of Cuyahoga Falls, Ohio, a graduate of the College of Physicians and Surgeons of Chicago in 1875, was killed in a railroad accident near his home on May 9, aged 60 years.

Dr. Erasmus V. Swing of Coatesville, Pa., a graduate of the Medical Department of the University of Pennsylvania in the class of 1867, a member of the American Medical Association and the Chester County and Philadelphia State Medical Societies, and attending physician to the Coatesville Hospital, died in Philadelphia on May 5, aged 71 years.

Dr. Augustus Grfelé Elliot, formerly of New York, died in Rostock, Germany, on May 11, aged 90 years. Dr. Elliot was graduated from Yale University in 1839. In 1843 he received the degree of doctor of medicine from the College of Physicians and Surgeons, New York, and later became attending physician to Bellevue and the New York Hospitals. He was also one of the founders of the New York Academy of Medicine. The last years of his life were spent abroad.

Correspondence.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

EXPERIMENTS ON THE SENSIBILITY OF THE ALIMENTARY CANAL—MEASLES, DR. MILNE'S TREATMENT WITHOUT ISOLATION, ETC.—OBITUARY.

London, April 28, 1911.

In the course of the Goulstonian Lectures at the Royal College of Physicians, Dr. A. F. Hertz gave an account of some experimental investigations directed toward determining the nature and the degree of the "sensibility of the alimentary canal." The response of the different parts to various stimuli in health, whether tactile, thermal, or chemical, has been too frequently inferred from symptoms bordering on, if not altogether due to, pathological deviations. The use of lavage and the *x*-rays has been a decided advance, but there still remain numerous points which need clearing up. In conjunction with others, to whom he makes due acknowledgments, Dr. Hertz concludes that the whole canal is completely insensitive to tactile stimulation. Thermal sensitiveness does not admit of this simple negation, but there seems a liability to error as to its localization. Drinking hot or cold fluid gives rise to distinct sensations which are also perceived when the liquid is passed through a tube. But the lecturer held this to be caused by conduction between the tube and mucous membrane. He found with a double tube three or four ounces of water could be

passed down the inner one before the outer became hot or cold. Observations on gastrostomized patients showed the same insensitiveness of the stomach. But by regulating the length of tube introduced so that the end was in the esophagus just above the cardiac orifice, a sensation of cold or heat was felt within one-half to one second, its character being the same as in swallowing. *X*-rays showed the position at which sensation was felt—generally within one inch of the lower end of the gullet.

Hot and cold metal bulbs passed through an esophagoscope so as to touch the mucous lining showed that the whole gullet is sensitive and that the localizing power is accurate. It was found that the sensation in the epigastrium began about three seconds after swallowing and lasted another three. Thus the sensation so generally ascribed to the stomach originates in the lower end of the esophagus and lasts for the period during which fluid is passing through the cardiac orifice. Some have ascribed the sensation to reflex in the skin, a view which the lecturer disproved by placing ice on the skin during experiments, when the patient recognized heat or cold, deeper than the skin, although it was introduced without telling him. In a woman with bulbar paralysis no thermal sensations were produced in the esophagus, which suggests they are conveyed by the vagi, not by sympathetic fibers.

Similar experiments showed the colon to be generally insensitive and this was confirmed in colostomy cases. The rectal membrane proved insensitive to hot and cold metal passed through a speculum. But the anal canal is very sensitive. The general conclusion as to thermal stimuli would thus seem to be that the ends of the alimentary tube (esophagus and anal canal) are very sensitive, but the intermediate part (stomach, colon, etc.) scarcely at all.

As to chemical stimuli the prevalent notion about acidity of the stomach receives a rude shock from the experiments reported in this lecture. HCl 0.4 or 0.5 per cent. introduced through the tube into the empty stomach produced no sensation of any kind—nor did it when passed through a gastrostomy wound. It was the same with organic acids (acetic, lactic), 1 per cent., an amount never present in gastric fermentation.

A very different result follows the ingestion of alcohol. Experiments with liqueurs passed through the tube into the empty stomach gave rise, sometimes immediately, oftener in a minute or two, to the sensation of warmth familiar on swallowing them. It was the same with alcohol diluted to the same strength, 48 per cent. When poured through the tube over the lower end of the esophagus the sensation was much stronger—in fact this point was so sensitive that extra care had to be taken to prevent a few drops falling on it as the tube was withdrawn in testing the stomach. The tube was retained in the stomach after all the test fluid had been passed half a minute and then a little water poured down to wash away any remaining drops. These results were also confirmed by observations on gastrostomized patients. In the anal canal alcohol above 25 per cent. gave a burning sensation, but in the colon through a colostomy opening from 50 to 90 per cent. was required.

These experiments call for a modification of various opinions. Thus it is clear that acidity is not the easy explanation of heartburn, pyrosis, regurgitation of sour fluid, etc. Neither will the contact of HCl fully account for the pain in ulceration. Yet acid seems to be connected in some way with such symptoms, for an alkali constantly affords prompt relief. Another symptom—distention—seems due to a different condition and required a different mode of investigation. A rubber bag was attached to a gum-elastic catheter and passed along the gullet to various distances and into the stomach. By a valve pump the bag was inflated, forming a balloon, and the tension exerted measured by a manometer. In the esophagus a lump was felt and sometimes a peristaltic wave was set up. This was seen too by *x*-rays and suggests that the expression of a lump of food sticking in the gullet is not unnatural, for drinking will dislodge such a bolus, as has been seen with *x*-rays. By inflating the stomach a sense of fulness was reached at 12 or 14 mm. of mercury. It fell about 2 mm. in twenty seconds. On injecting more air it recovered the 2 mm. and again lost them in twenty seconds. The same rise and fall occurred four times. The lecturer concluded that the intragastric tension on the circular muscle fibers is the cause of the sensation of fulness and the pressure required to produce the tension varies with the conditions. It would seem that a rearrangement of muscle fibers must occur in response to an increase of tension which produces the sensation of fulness. But this fulness may also occur from decrease. The symptom may therefore arise in the two opposite conditions—excessive or deficient gastric tone.

The epidemic of measles in London following the severe and fatal outbreak among the naval cadets has let loose a flood of articles in popular journals and newspapers. This is perhaps not extraordinary, measles being so common a disease of children, but no subject now seems to some writers or editors unsuitable for public discussion. Accordingly we have had numerous disquisitions on cancer, some well informed, some otherwise. Much more unsuitable, one would have supposed, for a journal catering for popular support, is such a subject as remedies for disease, especially such a one as 606, and yet this very drug has been freely discussed in a popular periodical. As a natural result I had a call yesterday from a gentleman who was desirous of discussing with me the various points set forth in the article and who seemed to think me actuated by a desire for professional secrecy when I advised him not to attempt to fathom the several puzzles he propounded until he had laid some groundwork in physiology. But to return to measles. There are not a few who desire that compulsory notification be adopted. But such a course is strongly opposed by others as quite useless. Among these is Dr. Robert Milne, who read a paper on the subject in the section for children's diseases on March 28 and who has had extensive experience as the medical officer of Dr. Bernardo's Homes, where 1,300 children are generally in residence. He has written several articles on scarlet fever and a small book, in which he has maintained that there is no need for either notification or isolation in this disease, because in his experience of over thirty years he has always found it amenable to treatment which not only cures the patients, but prevents the spread of the infection. Over 12,000 children have passed through the Bernardo homes during this period with altogether only 245 cases of scarlet fever. In these institutions when a child is admitted it is watched and if any infection is developed it is at once placed under treatment but is not isolated. [The doctor has no fear, however; many children are in the ward,

where the new patient mixes freely with all, uses the same toys, etc.] As one example of others: On March 8 he found a delicate boy in a dormitory where twenty-three others slept. Coryza and Koplik spots, etc., well marked; twenty-four hours later the rash came out and he had a severe attack. He was treated there and joined by two fresh arrivals and later by two others. All remained in the dormitory and the whole number joined in play and meals with his usual good results.

The routine treatment is at the earliest moment to rub pure eucalyptus oil all over the child, repeat this inunction night and morning for four days, afterward once a day until the tenth day of the disease. In addition the tonsils and pharynx are carefully swabbed with 1 in 10 carbolic oil every two hours for twenty-four hours—seldom longer. He takes a swab of cotton wool the size of the last joint of the patient's thumb in a pair of forceps or tied on a pencil and soaking it in the carbolic oil gently but as completely as possible swabs tonsils and pharynx. This treatment of scarlet fever Dr. Milne now extends to measles and if at present he has not so many facts to report he has abundance to justify him in urging his brethren to give his method an extensive trial. When he first adopted it he used carbolic oil for inunction, but for twenty-seven years he has employed the pure eucalyptus oil. He avers that with it secondary infections and so complications are unknown. Properly carried out he declares children may sleep in the same room and even the same bed without fear; the mother can attend to them at home, the father may go on with his work, and after-disinfection is needless, the infection having been destroyed by the treatment. Thus all the trouble and anxiety of isolation may be avoided and of course notification is unnecessary.

Dr. A. J. M. Bentley died suddenly on the 20th. He took M.R.C.S. 1871 and M.D. Ed. 1889. He had been physician to the Sultan of Johore, surgeon to the Leper Hospital and Chinese Hospital, Singapore, and held other offices. Subsequently he practised at Cairo in winter and at Llandrindod Wells in summer. He wrote a work on "Beri-beri" in 1893 and contributed papers on climatic and other subjects to the societies and journals.

You will know as much as we do about the massacre of an exploring party by the Abors of the Assam frontier. We have given up hopes that the medical member of the expedition, Dr. Gregorson, escaped. He was an experienced traveler in the East and knew the dangers of the last journey.

Surgeon-General William B. Beatson, I.M.S. (retired), died on Wednesday in his eighty-seventh year. He qualified M.R.C.S. in 1846 and proceeded to the Fellowship in 1867. The corresponding diplomas of the R.C.P. he added in 1884 and 1901. He was the author of a work on "The Indian Medical Service, Past and Present," and of journal articles on that subject. He also contributed to the *Asiatic Quarterly*, the *Indian Medical Gazette*, *Annals of Indian Medicine*, etc.

Major George Lambe, I.M.S., director of the Pasteur Institute at Kassauli, died on the 13th inst., aged only forty-two—a great loss to medical science. He made important investigations on snake poison, on Mediterranean fever, and other subjects. He served on the plague commission in India.

Bilateral Herpes Zoster.—Illuminati reports a case of bilateral and symmetrical herpes zoster affecting all branches of the trigeminal nerve and one branch of the facial nerve.—*Gazzetta degli Ospedali.*

THE DECREASING POPULATION OF THE PACIFIC ISLANDS.

(From Our Manila Correspondent.)

RABAUL, NEW GUINEA, March 12, 1911.

ONE of the most striking facts in the medical history of the islands of the Southern Pacific Ocean is the rapidity with which the native races are dying out since the advent of the white man upon their shores.

The independent testimony of reliable medical men, bishops, and others who live in those islands is practically unanimous that the population is steadily growing less. In Yap and in the nearby islands which are under the same jurisdiction the population ten or twelve years ago was estimated to be 12,000. Estimates made this year by the same sources place the population at 6,000 or less. Inquiry as to the cause of this decrease in those islands brings the answer that it is mainly due to tuberculosis and syphilis and other venereal diseases.

In German New Guinea the conditions are still so primitive and the country so unexplored that no one ventures to make an estimate of what the population was a dozen years ago or, for that matter, what it is now, but medical men, large planters, and other persons of experience agree that it is only half of what it was formerly. In New Guinea the introduction of smallpox has probably caused the greatest havoc. Until very recently vaccination was unknown and the unprotected natives died literally by the thousands. Bacillary dysentery was next introduced and now sweeps over the country in great epidemics. More recently influenza has been imported and a loss of from 10 to 20 per cent. of the population in the districts affected is not an uncommon experience. Tuberculosis and venereal diseases rank next on the mortality list.

In New Pommern the population is again unknown but from the best evidence obtainable there is not much doubt that the number of natives is rapidly decreasing. In those islands the causes are ascribed to the diseases given above with the addition of amebic dysentery and pernicious malarial fever.

In the Papua islands there is also a rapid decline in population. The very general introduction of venereal disease by the influx of white people, which was caused by the discovery of gold near Samarai, is responsible for much of the morbidity and mortality among the natives. Tuberculosis is gaining a strong foothold and bacillary dysentery and influenza with accompanying pneumonia are also causing a high death rate.

In the Gilbert islands in addition to the causes already cited, measles was introduced and has been responsible for many deaths.

On account of the very general interest at this time in the question of the etiology of beriberi, the result of an inquiry with regard to this disease may be of interest.

In Kaiser Wilhelms Hafen in New Guinea and vicinity, beriberi is frequently encountered on the large cocoanut plantations and occasionally a case comes to notice among the general population. In their natural state the staple article of diet of the natives is taro (a tropical sweet potato) and fish, and sometimes these are to be had only in small quantities. Game is rare so that not much meat is available, except that obtained by cannibalism. Upon the cocoanut plantations the owners find it

to their financial advantage to import rice and to issue this to their laborers as a ration, instead of attempting to grow rice or to use local food products. The imported rice is invariably of the white polished variety.

In New Pommern beriberi is very common among the dock laborers, plantation workers, and those employed upon sailing boats owned by the whites and Chinese. A few cases are encountered among the general population. Here again the natives in their natural state live mainly upon taro and fish and those who work for others as dock laborers, plantation workers, etc., use rice as a staple article of diet.

In Papua beriberi is very common, particularly near Samarai. An examination of the customs records shows that rice is imported in considerable quantities and its distribution is very general owing to the fact that many natives are employed in connection with the gold mining. Natives who are engaged in unloading ships, carrying supplies into the interior and those who work in the gold diggings almost invariably receive rice as part payment of their wages. No cases of beriberi were reported among any of the Europeans, although they frequently lived in close contact with the natives and at the places in which the affected natives were found.

The foregoing data seem to lend considerable support to the theory of those who believe that beriberi may be caused by depriving the human organism of those substances which are found upon the outer layers of a rice grain. In each instance there is a large incidence of beriberi among those whose staple article of diet is polished rice, while the disease is rare among those who use other forms of food. The small amount of beriberi among those who do not use rice as a staple article of diet may be accounted for by simple insufficiency of food or a poorly balanced diet.

The experiences related above may well give rise to the question: "Are the benefits bestowed by the implantation of civilization offset by the disadvantages?"

Among those who have made a study of similar conditions in the Philippines it has long been the belief that the population of those islands has been at a standstill or actually decreasing during the past few hundred years and that it was not until the effects of the wholesale sanitation which was introduced by the American occupation began to be felt that the population began to augment. It would seem, however, that some of the increase in population may be due to a gradually acquired immunity to the diseases which were introduced by civilization nearly four hundred years ago.

In view of the great amount of sickness and suffering it may be of interest to relate in the next letter what is being done to relieve the diseases introduced by the white man and for those which are indigenous. In making up the account of the diseases imported the fact must not be lost sight of that the Chinaman was also an important factor, although in most instances he only came after the white man had led the way.

Nitrogen Excretion of Normal Kidneys.—F. B. Barringer and B. S. Barringer, in comparing the quantities of nitrogen secreted by each kidney during the same length of time, note that once they were equal, six times they varied by less than 10 per cent. and four times they varied by between 10 and 20 per cent.—*American Journal of Physiology.*

Five Successive Cesarean Sections on the Same Woman, the Fifth on Twins; a Unique Obstetric History. C. M. Green.
A Summer Service in the Weld Ward of the Massachusetts General Hospital. C. J. White.

School Inspection in Small Towns.—A. T. Cabot describes the system of school inspection in Canton, Mass. The work is done entirely by a trained nurse, who looks after nine hundred children, examines them at the beginning of the year and records the results in a card catalogue. She afterwards keeps a record of any illness they may have and seeks in this way to have a complete medical history of all the children in town. Such children as show any infirmity of eyes, ears, throat, or general condition are referred to their physicians and are afterwards followed up to see that they get advice and follow it. Such children as need attention of a specialist and are unable to pay for it are taken by her to a public clinic in Boston. In addition to this care of the children's health she has also given talks on matters of hygiene in the schools, and her visits to the homes give her opportunities to illustrate and enforce this teaching.

Diagnosis of Advanced Renal Tuberculosis.—H. Cabot states that there are certain types of genitourinary tuberculosis in which error is difficult to avoid. This is particularly true of two classes of cases; first, cases occurring in the male with undoubted tuberculosis of the genital tract, primary in the epididymis or prostate with bladder involvement, in which the determination of the conditions in the kidneys is often difficult; second, cases occurring in the female in which the disease is primary in the Fallopian tubes, with bladder involvement, obscuring the renal condition.

Prostatectomy.—L. Davis continues his analysis of forty-six cases of prostatectomy.

Cesarean Section.—C. M. Green reports the case of a colored woman upon whom five successive cesarean sections had been performed; in the last operation twins were delivered.

The Weld Ward of the Massachusetts General Hospital.—C. J. White states that this ward of twenty beds, built by private generosity, was opened in October, 1903, and has proved of great benefit to many patients who otherwise would have found great difficulty in caring for their peculiar, and often crippling, diseases. Secondly, this ward has been of great service to the community in isolating many highly contagious cases of syphilis until their open wounds have cicatrized and thus rendered them less dangerous to their neighbors. Thirdly, this ward has been of great value to its staff and to medical students, who have found within its beds practically all the common diseases in their severest forms, and most of the rarest dermatoses. These beds have been the means of keeping within the hospital these many patients whose diseases could, therefore, be observed and studied until convalescence or death completed the cycle of their disease.

Salvarsan.—J. A. Fordyce states that to a patient with lues presenting himself in the primary or early secondary stage he would unhesitatingly recommend the drug if no contraindications existed for its employment. As the result of experience he now recommends the following procedure: An intravenous injection followed by a course of mercurial inunctions or injections over a period of from four to six weeks. At the expiration of this interval a second intravenous injection of salvarsan and a subsequent course of mercury. At the end of this treatment a rest of a month and a Wassermann reaction. If it is negative the patient is observed for one or two months, and a second serum reaction is made. As long as it continues negative no treatment is indicated. Should it become positive a third intravenous injection of salvarsan supplemented by a course of mercury would be the best procedure to adopt. It seems that this method offers to the patient a far better chance of a rapid and permanent cure than the use of mercury alone. Should the reaction become negative after a single injection of salvarsan, it may be well to act on the advice of Ehrlich and repeat the injection, because of the possibility of incomplete sterilization with the encapsulation of a few spirochetes in the bony canals and the danger of recurrence in the nerves of special sense.

Therapeutics of Syphilis.—V. C. Pedersen continues his article on this subject.

Typhoid Cholecystitis.—By J. E. Summers. See MEDICAL RECORD, February 25, 1911, page 364.

Hemorrhagic and Gangrenous Varicella.—F. C. Knowles states that there is a true form of hemorrhagic varicella, starting with the usual type of vesicles with clear contents, which some hours after their formation become filled with blood. It is a rare complication of varicella. The latter hemorrhagic vesicles may lead to the formation of gangrenous areas. The virulence of the infection and the resistance of the individual govern the hemorrhagic and gangrenous tendency. There is also a true form of varicella, in which the contents of the vesicles become purulent and may lead to gangrenous areas, but usually to the ecthymatous or impetigenous types. The term varicella gangrenosa should be applied only to cases of gangrene directly caused by varicella. The term dermatitis gangrenosa infantum should be applied to cases of gangrene in children, whether associated with varicella or not, if not directly dependent upon that condition.

Important Factor in Circulation.—A. Rose states that there are mechanical forces in the body which distribute the blood and other fluids. It is not the heart alone which moves the water, there are fluctuations of blood and other fluids in the body upon which the heart exercises no influence; their distribution in the body takes place in a threefold manner: 1. As blood or lymph in the vessels; 2. as tissue juice in certain spaces between and within the organs; 3. in constituting the most important part of the cells. A common feature of these three systems consists in the fact that they may be mechanically dilated or compressed, and they are also dilatable and compressible of their own force. The fluid contents of any part of the body may depend upon the condition of the tissue and be totally independent of the blood circulation in the vessels, because the distribution of blood or water is partly regulated by the function of the muscles and the influence of this function on the vasomotor nerves.

Cinematography of Gastric Peristalsis.—G. E. Pfahler concludes that cinematographic reproduction of the peristaltic wave of the stomach is at present possible by reducing and repeating separate exposures at comparatively long intervals. Bioröntgenography is at present of great value in demonstrating to an audience both normal and pathological movements of the stomach. In the near future one may hope to record cinematographically (ten or more exposures in a second) special phases during the study of a stomach upon the fluorescent screen. This may then make it of additional value in diagnosis, since the photographic plate is more sensitive than the eye. A careful study of the peristaltic wave will give the earliest evidence obtainable of carcinoma of the stomach.

Error in Gastric Analysis.—C. S. Fischer alludes to a possible source of error in the ordinary clinical method of extracting gastric contents for analysis. This error is based upon the imperfect homogeneity of the average gastric contents *in situ*.

Quinine and Urea Hydrochloride.—W. Green states that quinine and urea hydrochloride is a valuable and safe local anesthetic. A sufficient amount can be used to produce local anesthesia without fear of causing untoward systemic effects. Brewster having "used as much as a hundred grains" of the salt "intravenously in six hours with recovery of the patient." This amount is the equivalent of about one and one-fourth pint of a 1 per cent. solution. Anesthesia may be obtained in from three to forty-five minutes. In the majority of cases, in the author's experience, anesthesia was complete in ten minutes. While anesthesia may not be obtained as quickly as with cocaine, eucaine, or novocaine, it is just as profound and of much longer duration. The period of anesthesia varies from a few hours to several days, three days being the average in the experience of the writer. The bleeding is not wholly controlled though materially lessened, especially by the use of solutions of the higher percentages.

A Rare Manifestation of Empyema Necessitatis. J. H. Comroe.

Robert Koch.—S. A. Knopf states that after a lapse of nearly thirty years since the memorable discovery of the tubercle bacillus one can statistically prove that, thanks to the rational, practical, yet simple method of prophylaxis which soon followed the discovery, the mortality from tuberculosis has been on a steady decrease in nearly all civilized countries. While Koch is generally conceded to have been rather premature in his announcement of the value of tuberculin in the cure of the disease, his original claim has been justified by time and to-day his tuberculin has proved to be a valuable curative adjuvant in the treatment of certain cases of tuberculosis in the hands of careful clinicians. His conclusions as to the rarity of the transmission of bovine tuberculosis were also a little too sweeping.

Sporotrichosis.—J. M. Sutton believes that this disease is fairly prevalent in the rural districts and not so rare as has been supposed. The diagnosis presents some difficulties at times. It is possible that cases have been mistaken for tuberculous lymphangitis. Unfortunately, the infection is usually treated surgically and the patient undergoes weeks and months of needless suffering. As others have pointed out, a traumatic lesion of the arm, resistant to ordinary surgical treatment and accompanied by one or more sharply defined painless abscesses along the course of the lymphatics, should always arouse suspicion, espe-

cially if the inflammatory manifestations of ordinary coccic infection are lacking.

Extensor Toe Reflex.—T. B. Throckmorton, has found that the extensor toe reflex elicited by the Babinsky, Gordon, and Oppenheim methods, and which is generally taken as differentiating between organic and functional nerve lesions, can be elicited by percussion of the base of the great toe. The muscles of the leg should be in a relaxed condition and the toes passive. The skin overlying the upper surface of the first metatarso-phalangeal articulation, when struck with the pointed end of a percussion hammer just within the tendon of the extensor longus hallucis muscle, will produce the reflex. The force of the blow required will vary in different persons, some requiring but a few light taps while others may need several fairly sharp blows. In all cases which he has observed he finds that the more marked the Babinski reflex the less force is required in percussion. He has not found this in any normal individual, but in patients in whom the Babinski method failed this method also failed. In cases in which the parodoxic flexor reflex could be obtained but the Babinski method failed his percussion method was also ineffective.

Sporotrichosis.—H. J. Harker reports a case of this condition.

Anesthesia.—I. C. Herb states that unless the anesthetist keeps in touch with the operator he cannot interpret changes in the circulation and respiration directly due to the operative procedure, nor can he tell the degree of narcosis required. It is not necessary to watch every step of the operation, but an occasional glance at the operative field will keep one posted as to the needs. Reflexes and respiratory inhibitions have great importance and should be understood by anesthetists and operators, and some of these are specially mentioned. The author describes the open method of etherization the superiority of which has been shown by its increasing popularity both here and abroad. She also describes and recommends a restraint apparatus to be used, and specially condemns the administration of drugs before anesthesia. The quieting effect of combination anesthesia thus produced is no offset to its disadvantages.

Family Pernicious Anemia.—A. J. Patek concludes that the clinical history and blood-findings permit of no doubt that five of the patients whose cases he reports (two brothers and one sister, a paternal cousin and a paternal uncle) suffered from primary pernicious anemia. The weight of evidence which the two cases of secondary anemia add is not to be wholly ignored, because anemia of the secondary type has frequently been known to be a precursor of the primary form. Hunter's theory, so strongly defended by him, that septic conditions in the mouth—stomatitis, glossitis, etc.—are the etiological factors in this disease sheds no light on this series of family anemias. (No such mouth condition existed in any of the cases.) The possibility, as here shown, of its being a family disease and the knowledge that the disease is on the increase—not only relative, but absolute—suggest an as yet unrecognized source of hemolysis that is showing increased general activity, and is uninfluenced by environment or station.

Medical Practice Acts.—M. L. Harris believes that the restrictive plan of regulating the practice of medicine is a failure. If it were possible to enact a law prohibiting anyone from practising medicine who was not licensed to do so after examination proving his qualifications, the author thinks that it also would be a failure. He does not believe the state has a moral right to take away anyone's right of choice in such a matter as the care of his health, or to dictate to the patient whom he shall employ for this purpose; the attempt to do so arouses public opposition to the extent of sometimes nullifying the law. The correct method would be that the state should guide the individual, not force him in these ways. It should license competent men and allow them alone to utilize the designation indicating their qualification, whether it be qualified physician, certified physician, or what not, and should make it a penal offense for anyone else to use it. Furthermore, it should require that any other person professing to treat the sick, in any manner whatsoever, than those thus qualified should be compelled to announce in his card or advertisement that he is not a qualified physician. None but these latter should be eligible to any medical position under the state or municipalities and, as contagious cases are a menace to the public and as most of them should be reported to the proper health officers, only the qualified person should be permitted to assume their medical care. None but a qualified physician should be allowed to make out a death certificate and no parent or guardian, or other having charge of minors or others for whom they are responsible, should be allowed to put them in the care of unqualified persons.

Milk and Tuberculosis.—A. F. Hess concludes that of eighteen children who drank milk in which tubercle bacilli were demonstrated, all but one remained free from active tuberculosis during a period of supervision of three years; this one developed tuberculosis of the cervical glands, from which a bacillus of the bovine type was cultivated. From animal experiments one can conclude that the chance of infection through milk depends not only on the number of bacilli ingested, but also on the frequency of exposure to small infections. For a quantity of bacilli which was insufficient to produce tuberculosis in guinea pigs when given in one dose, suspended in milk, was able to incite tuberculosis when fed in from twenty-five to thirty doses on as many days. Tubercle bacilli in milk are a menace to the health of young children. Tubercle bacilli in butter are likewise a menace; therefore, a safe butter, whether pasteurized or certified, should be provided for their use.

Uterine Fibroids and Cardiac Disorder.—R. L. Payne, Jr., states that in a large percentage of cases of uterine fibroids there are present symptoms of cardiovascular disturbance. The size of the growth has no relation to the severity of the cardiac disturbance; symptoms have been apparent while the growth was still small. In some cases of lost cardiac compensation associated with fibromyomata the symptoms are materially benefited by removal of the growths. In some cases the cardiac disturbances are of so severe a type as to result in sudden death following operation. The first signs of cardiovascular disturbance associated with uterine fibroids should be an indication for immediate operation, and the watchwords in these cases should be: (a) rapid surgical technique; (b) careful hemostasis; (c) as little handling of the viscera as possible, and (d) the greatest caution against overtaxing the heart during postoperative treatment.

Elastic Tissue Stain.—F. H. Verhoeff describes an improved differential elastic tissue stain.

Mammalian Parthenogenesis.—L. Loeb states that his observations demonstrate that chorioepitheliomata and teratoid tumors that are found in the ovaries are not derived from misplaced blastomeres, as Bonnet and Marchand believed, but that the older view is correct according to which at least the teratoid tumors of the ovary are derived from parthenogenetically developed ova.

Empyema Necessitatis.—J. H. Comroe states that, generally speaking, the term "empyema necessitatis" refers to an empyema in which pus can make a spontaneous escape. Some authors limit the term to the condition in which the pus makes its escape through the chest wall. Empyema may rupture into the esophagus; into the bronchi; through the chest wall; through the diaphragm into the peritoneal cavity; into the pericardium, etc. This

spontaneous rupture is a very rare manifestation of empyema complicating pneumonia, especially in an empyema of short duration. Kerley reports one somewhat similar case of rupture into the bronchi, in a well-nourished boy of three years. Holt states that of nineteen cases of empyema in children, reports of which were collected by Schmidt, "in which a spontaneous discharge of pus occurred either externally or through a bronchus, there were seventeen deaths and two recoveries."

Two Interesting Cases of Acute Intussusception and Appendicitis. L. C. Martin.

Plague.—Wu Lien-Teh (G. L. Tuck) states that the marmot is responsible for the present epidemic of plague in Manchuria. The marmot skins have been in great demand in European and American markets, and numbers of wandering Shantung coolies have, in consequence, found their way to the marmot resorts, hunting it indiscriminately, and, food being scarce, often cooked and ate the flesh of the marmot. A number of these Shantung men have died in previous years, but not in sufficient numbers to attract attention. The season for killing marmots is from August to the middle of October. About the third week in October of last year there were said to be fully 10,000 of these hunters gathered in Manchuria and Khailar, with their skins, waiting to sell them and then to return south for the winter. Dr. Chuan found out that the symptoms of sickness suffered by these hunters were headaches, fever, and spitting of blood-colored sputum, followed by rapid death.

Sensibility of the Alimentary Canal in Health and Disease.—A. F. Hertz states that the sensation of fullness in the intestines is due, as in the case of the stomach, to tension on the muscular coat. The call to defecation is a specialized form of visceral muscle-sense. It is the result of the pressure exerted on the rectal wall by the feces on their entry from the pelvic colon, the urgency of the call depending upon the tone of the circular muscle fibers of the rectum at the time and the bulk and consistency of the feces. Disease of the alimentary canal may cause true visceral pain, which is often present alone, but may be associated with pain which is referred to the skin, muscles, and connective tissues connected with the same spinal segments.

Microbic Factor in Gastrointestinal Disease.—B. Dawson states that his experiments show that pathogenic organisms can exist in the stomach with a normal or a raised hydrochloric acid content. Just as infection is a factor among others to be considered in gastrointestinal diseases, so vaccine therapy takes its place for consideration beside other treatment. No doubt careful eating and drinking, less worry and work, more fresh air and exercise, are potent factors in curing digestive derangements. But such lines of treatment are not always sufficient even if they are feasible.

Tuberculous Joints Treated by Ileocolostomy.—H. Chapple states that, having established that in persons who are suffering from a condition of chronic intestinal stasis there is taking place from the large bowel an absorption of toxic material which is capable of producing such gross changes as skin staining, cystic degeneration of the breasts, etc., Arbuthnot Lane raised the question of the effect of this chronic absorption on the resistance to bacterial infection. If one carefully examines a number of such patients there will be no doubt on the evidence obtained that the general resistance is low, nor does it seem at all extraordinary that this should be so. Having observed the sequence of a tuberculous infection on the top of a condition of old intestinal stasis in a large number of cases in 1909, Mr. Arbuthnot Lane commenced the treatment of advanced tuberculous joints in patients who showed the signs of intestinal autointoxication by ileocolostomy. Since then the author has been able to confirm this sequence in a large number of cases of chronic tuberculous lesions in the out-patient department of Guy's Hospital.

Lymphadenoma.—E. P. Straford reports a case of lymphadenoma affecting the mesenteric glands, probably mainly those in the portal fissure and the duodenal area. In its earlier stages the case presented an absolutely true clinical picture of gallstone colic.

Intussusception and Appendicitis.—L. C. Martin reports a case of the former in an infant seven months old, successfully operated upon. Postoperative vomiting was relieved by gastric lavage. A case of appendicitis is also reported in which an unusually rapid fatal ending after operation was found to be associated with a double pyosalpinx. The lesson taught by this case is the necessity of inspecting the right tube when operating for appendicitis in women.

Radium Water Therapy. W. Armstrong.

Persistence of Disease Germs in Body.—Sir Hector C. Cameron reports a series of cases to illustrate the persistence of pathogenic microorganisms in the human body. The cases are as follows: 1. Recurrent erysipelas, in which a fresh traumatism aroused the virulence of germs lying quiescent in a part in which they have on a former occasion caused widespread disease. 2. Recurrence of staphylococcic osteomyelitis. 3. Recurrent staphylococcic abscess in right tibia nine years after amputation of the left leg on account of acute osteomyelitis of the left tibia. 4. Ostitis of femur occurring in a man, 54 years of age, four or five months after recovery from a large carbuncle on the neck. 5. A case of empyema due to *Staphylococcus pyogenes albus;* recurrence of suppuration nearly three years afterwards, the same organism being present. 6. Repeated attacks of severe pain in a tibia for twenty-seven years subsequent to the occurrence of typhoid osteitis with abscess in that bone. 7. Case illustrating the persistence of typhoid bacilli in the gall bladder. 8. Amebic abscess of the liver occurring more than six years after recovery from an attack of dysentery.

Salvarsan and Arsenic Cancer.—Sir Jonathan Hutchinson alludes to a possible danger in the treatment of syphilis with salvarsan. It has been proved that the use of arsenic may create a proclivity toward malignant forms of growth. These are not by any means always the same; most conspicuous and frequent are epitheliomata, but they are by no means the only ones, for various forms of sarcomata and probably endotheliomata occur in the same connection, and possibly in the same individual. If it be asked how arsenic acts in giving proclivity to cancer, it may be suggested that it is as a depressant of growth power rather than as stimulating it. By diminishing the vigor of the forces which favor normal animal organization it permits remotely and after an interval of degraded types of growth more nearly allied to those of vegetation.

The Hospital in a Civilized Community.—L. E. Shaw states that the hospital should undertake to see and treat those patients only who, having already sought the assistance of a medical man—be he private practitioner, club doctor, officer of the Poor Law, or of a provident medical institution—are found to require some additional special advice or treatment such as they are unable to pay for and such as is within the capacity of the hospital to supply. In other words, the hospital should be a second line of defence or reserve—a purely consultative institution.

Syphilitic Factor in Infantile Hemiplegia.—C. R. Box states that the general consensus of opinion is that syphilis is not a common factor in the upper neurone paralysis of childhood, and this opinion appears to be based on very good grounds. Nevertheless, a reconsideration of the part syphilis plays may be instructive and appears to be desirable for two reasons: first, because, in some cases at least, a permanent and crippling disability of both body and mind may be prevented by an intelligent anticipation of events; and, secondly, because, thanks to the methods of diagnosis perfected of late years, it may yet turn out that syphilis is a more important factor in the production of these paralyses than many have suspected.

The X-Rays in Treatment.—J. R. Riddell discusses the value of the *x*-ray in the following conditions: rodent ulcer, keloid, psoriasis, lupus vulgaris, tuberculous glands, exophthalmic goiter, alopecia areata, leucemia, hyperidrosis, hairy and pigmented moles, nevi, deep-seated malignant disease, ringworm, and favus.

Venous Infection Complicating Middle-ear Disease.—N. Patterson records a case of recovery after widespread involvement of the venous channels. The internal jugular contained infected clot down to a point a short distance from its termination, and the lateral sinus was thrombosed in nearly its whole extent. The condition of the patient for close on three weeks after the operation, with recurring rigors, looked hopeless. The occurrence of a thoracic empyema on the opposite side of the body is of interest. The organism responsible for this condition was the *Bacillus coli*, whereas that obtained from the jugular vein was the *Staphylococcus aureus*. It is difficult to judge the effect of the injections of vaccine; their administration was followed by no very definite signs of improvement. This seems, however, a line of treatment that ought not to be lost sight of.

Malignant Disease of Spine.—T. D. Luke reports three cases of this condition.

Cases of Medicolegal Interest.—L. A. Parry reports a series of cases in which the medical referee was called upon to decide points of difference that arose between casualty companies and claimants under the workmen's compensation act.

Radium Water Therapy.—W. Armstrong reports good results following the use of a strong radioactive water, both for drinking and for bathing purposes, in the following conditions: diabetes, glycosuria, albuminuria, arteriosclerosis, gout, rheumatism, arthritis, neuritis, neurasthenia, and general loss of vitality, autointoxication, and sympathetic nerve and vasomotor troubles, such as angioneurosis.

Extirpation of a Large Angioma of the Brain.—Cassirer and Mühsam report a successful case of this intervention. The former made the examination and diagnosis of a brain tumor and located its site. Patient, a man aged 22, gave history of Jacksonian epilepsy of the sensory type, the sense of touch being abolished. This exclusive type of paralysis has great significance in localization, pointing to an affection of the posterior central convolution. The slow, progressive type of evolution of the epileptic attacks pointed to a neoplasm, and naturally to a benign one. The general condition was good, and pressure symptoms were absent. The entire history deals almost solely with the abolition of tactile perception in the left hand. This was the sole sensory component. Slight motor components affected the face, arm, and leg (twitchings, tonic spasm, etc.). The operation was performed by Prof. Mühsam. After craniectomy over the diagnostic area the dura was punctured and the presence of a cyst excluded. All the evidence pointed to an angioma of the pia mater which had invaded the cortex. Eight days after this exploratory operation the mass was extirpated. Its area was that of an adult palm of the hand. After ligation of some vessels the wound surface became dry and the dural wound and cranial window were closed. The wounds all healed smoothly, but the operation was followed by paralysis of the left facial nerve, arm, and leg, which soon disappeared. Epileptic attacks ceased. Patient able to resume his occupation. The particular type of tumor—angioma racemosum growing from the pia—is very rare, and not to be confounded with the cavernous and nevus types.

Therapy of Pyelitis Gravidarum.—Markus asserts that this condition is one of the most frequent causes of interruption of pregnancy. Its causation is still hypothetical. Obstruction of the right ureter is a factor, but the causation of the obstruction is by no means apparent. It has been noted that the left lateral decubitus causes the affection to subside, and such a fact goes to show that in some cases at least the obstruction of the right ureter is due to compression by a uterus turned to the right. The author mentions two personal cases, and also refers to the brilliant results of Rosinsky, who was the first to call attention to this method of cure. In all cases of pyelitis gravidarum we should test the effects of left lateral decubitus on the urinary stasis.

Röntgen Rays in Gynecological Practice.—M. Fraenkel has produced a complete monograph on this subject. In summing up he states that the brilliant results attained by some operators tend to show that negative results must often be due to defective technique. The author has himself had an extensive experience and has obtained excellent results in myoma of the uterus, dysmenorrhea, leucorrhea, and sexual disturbances of nervous origin. An entire series of gynecologists have confirmed the author's results. Osteomalacia has also yielded to the *x-rays*. Conception may be prevented *pro tem.*, and complete sterilization as well in cases of insanity, pulmonary, cardiac and renal diseases, syphilis, and sexual hyperesthesia. Improvement in myoma cases becomes evident as the hemorrhages become less. In perhaps one-fourth of myoma cases the action of the rays is negative. In climacteric hemorrhages with the uterus still large the *x*-ray is practically a specific.

Salvarsan in Malignant Tumors.—Czerny and Cann of the Heidelberg Cancer Institute sum up their studies in this direction as follows: In inoperable malignant diseases with positive Wassermann reaction, especially in sarcomata, salvarsan is able to influence the growths favorably, by promoting liquefaction and necrosis. Operable sarcomata must be treated with the knife, although salvarsan may first be tested, just as Esmarch used to first employ potassium iodide. After weakness and cachexia have developed salvarsan cannot be used by reason of the severe reaction which may develop. The dose used for syphilis is too small to affect malignant growths, and while the authors would not increase the single dose they would repeat it several times, because the relative

hopelessness of the patient seems to justify such a course. Salvarsan may be injected directly into the tumor and also into a vein. That this remedy should be antimalignant is not singular. Arsenic is one of the few known substances which can modify epithelial growth. In addition Köbner cured a number of cases of malignant lymphoma of the neck by injecting Fowler's solution. There is further some obscure connection between certain sarcomata and syphilis, in virtue of which the former yields to antisyphilitic remedies.

Pregnancy Diabetes.—Ehret discusses briefly this subject, which has of late attracted renewed interest. Diabetic women are able to conceive and bear children, but not in the same degree as the nondiabetic. The author considers only the diabetes which develops in pregnancy. This is a rare complication. Apparently it does not differ from simple glycosuria of pregnancy, save, perhaps, in degree, and in the persistence of the former after delivery. A case is given from which it appears that glucose was present in the urine in large quantities, which could be reduced by diabetic diet. The patient was controlled for sixteen months after delivery and carbohydrate intolerance was present after dietetic errors. The patient's mother had died of diabetes. It is of further interest to note that the patient's diabetes corresponded in type to Naunyn's paradoxal diabetes, *i.e.*, a small reduction in the diet carbohydrates caused a disproportionately large reduction in the sugar excreted; while to secure complete relief from traces of sugar it was necessary to use very strict diet. There were absolutely no evidences of impending acidosis. In order to account for pregnancy diabetes it is best to assume the existence of an inherent carbohydrate intolerance. Cases, a few, are upon record, in which a history of transient glycosuria had occurred before conception. Pregnancy causes an exacerbation, which may or may not affect the subsequent condition of the patient.

Unusual Cause of Tetanus.—Laubenheimer and Caan, after mentioning certain good results following the enzyme and radioenzyme therapy of malignant disease, relate a case of fatal tetanus in a boy of seventeen who was hopelessly affected with lymphosarcoma of the neck. Four operations had been performed for the growth and its recurrences. Salvarsan had given no relief. The patient was cyanotic from compression of the veins. A preparation was now injected into the mass which was composed of trypsin, powdered animal charcoal, and radioactive matter (nature not specified) which had previously shown itself to be possessed of a remarkable selective action. The charcoal was believed to activate the trypsin and at the same time antagonize unpleasant collateral effects. This combination and radium emanations are believed to act as synergists. After death of the patient from lockjaw an exhaustive study led to the conclusion that the tetanus bacilli must have preexisted in the medicament. Naturally enzyme preparations cannot be sterilized by heat, but whether the trypsin or charcoal contained the germs cannot be ascertained. The radioactive substance is said to be prepared with the aid of gelatine. This is supposed to be sterilized, but there is no certainty on this point. The entire medicament caused tetanus in mice, but none of the three components could cause it singly. It will, therefore, be necessary in the future to test only partially sterilized substances of this kind on small animals.

Prognosis and Course of Pneumococcus Meningitis.—Rolly calls attention to the high mortality of this affection. Of thirty cases treated at the Leipzig Clinic during the past five years, but four terminated in recovery. This is some improvement on the experience of others, who have never seen recoveries. The mortality corresponds with that of meningococcus meningitis before the introduction of serotherapy; if anything, it is higher. But eight of the thirty cases were associated with pneumonia, and of the four recoveries three cases were of this type, showing plainly that this association of lesions does not render the prognosis more hopeless. Much more common is the previous existence of pneumococcus sepsis and endocarditis (20 per cent.) and most frequent of all is preexistent rhinitis, or sinusitis and otitis (40 per cent.). In only 10 per cent. of cases was a previous pneumococcus lesion unaccounted for. It is well known that meningitis is very rarely a complication or sequela of a preexisting pneumonia (only six cases in a material of 1,050). The diagnosis of pneumococcus meningitis is made naturally after the discovery of the microorganism in the spinal fluid, but it may also be made by ordinary clinical resources. Naturally the parallel with meningococcus meningitis is so close that in many cases spinal puncture must decide. This is especially the case when the disease originates in the nasal fossæ and extends into the brain by way of the lymphatics. In other cases the preexistent or primary lesion may furnish a clue. If sepsis is present blood tests should decide the matter. The treatment is confined to repeated lumbar puncture, intradural injection of pneumococcus serum (now being tested), and large doses of urotropin.

Diagnosis of Gout by the Purin Metabolism.—Magnus-Levy writes briefly on this subject. A patient aged 43 gave a history of attacks suggesting gout but at consultation was free therefrom. One attack had been seen by a surgeon and diagnosticated as inflammatory flat foot. The diet was supervised until nitrogenous equilibrium was attained. The exogenous uric acid was promptly excreted, while the endogenous acid had a relatively high value. Gout was excluded, and the *x*-ray showed the presence of exostoses and other changes in the metatarsal joints, evidently not of gouty origin. Still there had been a tophus in the right ear, and during the period of observation unmistakable tophi appeared in the left ear. But the patient had flat feet, and atypical changes in the metatarsals as well. The case is accounted for if we bear in mind that these mechanical conditions invite a gouty localization. The so called "inflamed flat foot" can be nothing but gouty flat foot. The purin metabolism has the following relation to the gouty state. If a purin-free diet is employed the gouty excrete less uric acid than the healthy and if a purin-rich diet is given the exogenous uric acid is excreted more slowly than in the healthy. Judged by these tests the patient could not have had gout, yet they cannot be made to hold for every case of gout, and in the author's case they gave negative findings.

Etiology of Scarlet Fever.—Bernhardt has sought to study this subject in animal experimentation. He selected various species of monkeys and assured the existence of a specific virus in the coating of the human tongue in the early stage, before streptococcic complications could have set in. The virus, specially prepared, was inoculated into the groins, and mucosa of the cheeks and tongue. The lymphnodes in the groin swelled promptly, and one animal died of streptococcus sepsis. The other results are summed up as follows: There is a virus in the tongue coat, cutaneous lymphatics, and lymphnodes of scarlet fever which (save in accidental streptococcus infection) may set up a scarlatina-like syndrome in monkeys. This virus and disease may be propagated from one animal to another in series. The author was unable to throw any light on the nature of the virus.

Book Reviews.

The Work of the Digestive Glands. Lectures by Prof. I. P. Pavlov, Director of the Physiological Section of the Imperial Institute of Experimental Medicine and Professor in the Imperial Military Academy of Medicine, St. Petersburg; Foreign Associate of the Academy of Medicine, Paris, etc. Translated by W. H. Thompson, Sc.D., M.D., F.R.C.S. (Eng.), King's Professor of the Institute of Medicine, Trinity College, Dublin; late Dunville Professor of Physiology, Queen's College, Belfast; Honorable Member Imperial Military Academy of Medicine, St. Petersburg, etc. Second English edition, illustrated. London: Charles Griffin & Company, Limited. Philadelphia: J. B. Lippincott Company, 1910.

It is a pleasure to welcome the second English edition of these most important lectures by Professor Pavlov on the work of the digestive glands. It may be said that the volume contains almost all of the fundamental experimental work done on the gastro-intestinal tract during the past twenty years. The chief alterations in the new edition are in the chapters on the salivary gland secretion, which have been rewriten by Professor Pavlov. Two additional chapters on muscular movements of the alimentary canal have been added by the translator, bringing the work thoroughly up to our most recent knowledge of the subject.

Modern Treatment: In Contributions by American and Foreign Authorities. Edited by Hobart Amary Hare and H. R. M. Landis, M.D. Vol. II. Illustrated. Price, $7.00. Philadelphia and New York: Lea & Febiger.

This, the second and final volume of Hare's Modern Treatment, has twenty-one contributors, nineteen of whom are of native stock, one is French, and one English. Perhaps the outstanding monograph in the book is that by the English, or to be accurate, Scotch contributor, James Mackenzie of London. It would be somewhat idle praise to state that Mackenzie probably knows more concerning heart disease than any living man. He has been a pioneer of this branch of disease and has, to a large extent, revolutionized views and treatment as to heart affections. The make up of a good physician is first to be able to diagnose correctly and then to treat effectively. Although, perhaps, there are many medical men who have not been converted wholly to Mackenzie's views with regard to the causation of heart disease, yet more have been converted and his opinion carries such weight that his diagnostic acumen is regarded with respect and his methods of treatment looked upon with an equal degree of consideration. His paper in this book is worthy of his reputation. Another article by a master of his subject is on malarial infection and some other tropical diseases by Charles F. Craig of the United States Army. Craig has had wide experience of tropical maladies and he writes instructively and with authority. His remarks on quinine are deserving of close study. Another United States Army medical officer, L. Rhoads, contributes an uncommonly good paper on the dysenteries, from which one may learn the most effective modern modes of treatment. The chapter on bacillary dysentery is especially excellent and his suggestions as to prophylaxis against this disease would, if carried out, undoubtedly diminish its prevalence and in course of time might stamp it out completely. Other papers of interest are by S. P. Beebe, on "Diseases of the Thyroid" and "Thymus Glands"; on "Pellagra," by H. F. Harris; and on "Morbid Habits" by F. X. Dercum. Beebe states that he has treated between 800 and 900 cases of Graves' disease by means of cytotoxic serum with satisfactory results. Harris seems to be convinced that pellagra is originated by the consumption of spoiled maize and ignores the work and deductions of Sambon and others with regard to its causation. The chapters by Dercum on the treatment of drug habits are suggestive. He points out that a prolific source of the morphin or opium habit is the ease with which narcotics can be purchased in consonance with the laws and recommends the strict enforcement of existing laws regulating the sale of such drugs. Vol. II of Modern Treatment is full of good material, well written, well printed, and fittingly illustrated.

Abhandlungen über Salvarsan (Ehrlich-Hata Präparat 606, gegen Syphilis). Gesammelt und mit einem Vorwort und Schlussbemerkungen herausgegeben von Dr. Paul Ehrlich, Geh. Obermed.-Rat a.o. Professor, Direktor des Instituts für experimentelle Therapie, Frankfurt a. M. Preis M. 6. München: J. F. Lehmann's Verlag, 1911.

These discussions of salvarsan collected by Ehrlich contain but little which has not already been excerpted for American journals. In the preface he gives as reason for publication that since the first experimental stage is past, the results thereof may guide physicians in methods of use, indications and contraindications, primary and secondary effects, and dosage of the drug. He expresses the sincere hope that even though a single injection may not cure syphilis, repeated injections combined with other therapy will succeed. The section on technique is covered by Alt, Schreiber, Duhot, and Hausmann, the most important paper being that of Schreiber, wherein he describes his intravenous apparatus. The retention of salvarsan in the body has been studied by Fischer and Hoppe, Greven, Schwartz, and Flemming, and Hering. The investigations of the first mentioned authors showed that the urine became free from arsenic after ten days, the feces practically free in four days, but that 80% of the arsenic could be found in the gluteal muscles five weeks after injection. Among the voluminous clinical reports, there are but two original contributions, those of Grouven and Faveuto. Their results differ inconsequentially from others. In Duhot's report (in French) of his 400 cases, he scathingly criticizes statements of certain French physicians derogatory to salvarsan. Eitner's case of functional bladder disturbance, Ehler's fatal case, and Taege's report of improvement in a suckling child by injecting its mother, are all too well known to warrant comment. The results following injection in syphilitic lesions of the central nervous system and eyes are reported by Treupel, Willige, Benario, Hirsch, and Shanz; cardiac contraindications by Grassmann. Strong of Manila, in an original communication, cites the beneficial effects of the drug in a case of yaws, and Haller of Saratow relates its happy effect in a variola patient. In conclusion, Ehrlich makes no extravagant claims for his drug, realizing that the great subject of treatment of syphilis cannot be solved in a few months. He answers Hallopeau's attacks in dignified statements, admitting that although atoxyl causes eye damage in from 1 to 2 per cent. of cases, yet he knows not of a single instance of blindness following salvarsan injection. He analyzes the reports of secondary ill-effects and fatal cases, showing wherein faulty technique or bad judgment were important or probably wholly responsible factors. The indications and contraindications which he outlines are sufficiently well known. Combined therapy is advised, it being logical and practical to attack the parasites doubly. In the use of salvarsan he advises large doses in the most absorbable form. This collection of publications is replete with repetitions and unimportant details in case histories. The book would have been much less wearisome had these been eliminated.

The Physiology of Reproduction. By Francis H. A. Marshall, M.A. (Cantab.), D.Sc. (Edin.), Fellow of Christ's Church, Cambridge, and University Lecturer in Agricultural Physiology. With a preface by Prof. E. A. Schäfer, Sc.D., LL.D., F.R.S., and contributions by William Cramer, Ph.D., D.Sc., and James Lochhead, M.A., M.D., B.Sc., F.R.C.S.E. With illustrations. London, New York, Bombay, and Calcutta: Longmans, Green & Co., 1910.

Since English scientists, among them notably Sir Francis Galton and Karl Pearson, have contributed so much to the development of what is now known as eugenics, it seems most fitting that a textbook on the physiology of reproduction should also appear under English auspices, written by one who not only has been in touch with British investigators on the subject, but has himself contributed matter of no little importance on this still somewhat obscure and most complex phase of morphology and physiology. The treatment of the subject is, naturally, frankly comparative. As an example, in the first chapter which discusses the "breeding season," the illustrative material is drawn from the protozoa at one end of the scale to the mammalia at the other. Many of the histological illustrations are drawn from the tissues of the lower animals, especially where stages not easily obtainable from human material are concerned. Wherever human tissues are available, however, they are fully pictured. While the entire work is filled with interesting information, perhaps the best chapters are those devoted to the anatomy of the placenta and to the changes induced by pregnancy in the female generative organs. In an interesting chapter on the factors which determine sex the author gives a very full and judicious review of the various theories which have been presented and earns our gratitude by not adding a new one of his own. A chapter on the duration of life and the cause of death completes this very interesting and suggestive work, which should be read by every physician, although but little of its contents may concern his immediate practical activities. The illustrations, the type, and the index are excellent.

Society Reports.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, Held March 27, 1911.

The President, Dr. James F. McKernon, in the Chair.

The Use of the Hiss Extract of Leucocytes in Infections, Particularly Erysipelas, with a Report of Cases.—Dr. James G. Dwyer read this paper. As a result of experiments Hiss came to the conclusion that in many diseases they were probably dealing with an immunity a large part of whose mechanism was individually cellular, not only in the sense of phagocytosis and digestion, but in the neutralization of poisons given rise to by the disintegration of the bacteria, a mechanism in which the protecting cells must intervene and, unaided by bodies in the plasma, neutralize within themselves the poisonous products of the invading organisms. From this conclusion it was but a short step to the further idea of aiding the leucocytes by furnishing them with the weapons which were being taken away in their fight with the invading microorganisms and to thus protect them from destruction and give them a chance to recuperate and carry on successfully their struggle against the invading germs. He assumed that an extract of leucocytes might be efficacious in doing this, and since an extract was readily diffusible it would probably be distributed to all parts of the system through the circulation and, as quickly as an absorption would permit, relieve the fatigued leucocytes and protect by their toxin-neutralizing or other power the cells of highly specialized functions. This was the fundamental idea underlying the use of such an extract, and the use of the vaccines and antisera was obvious. If their theory was correct this extract should be most beneficial in those infections in which the main factors of defense were the leucocytes, especially those due to the staphylococcus, streptococcus, pneumococcus, and the meningococcus. Since Dr. Dwyer's last report, in March, 1910, among the other infections the streptococcus included 40 cases of erysipelas, 4 due to lateral sinus thrombosis and mastoiditis (3 recovered, 1 died), 2 to a local infection (recovery in both), 1 endocarditis (recovery), 1 multiple arthritis with recovery, 1 very virulent streptococcus infection of the throat, nasopharynx and double mastoiditis complicating scarlet fever (recovery), 1 streptococcus sore throat (with recovery, and 2 general streptococcus septicemia, with positive blood cultures and a fatal result in each. Of his series of cases of erysipelas there was but one fatal result. This occurred in an infant five months old on whom a double mastoidectomy had been done. This was followed by erysipelas, which was present two weeks before the leucocyte extract was given. Undoubtedly a septicemia was present in this case. The results obtained in this series of cases had been so uniformly good and so marked that he thought they must be more than a mere coincidence. The extract practically took the place of all stimulation, and some of his most severe cases had been kept comfortable by the use of the extract even when the temperature continued high. In such cases the pulse rate did not generally rise above 100° F., thus showing the great saving to the economy. Undoubtedly the duration of the disease was shortened in practically all of the cases, the average duration after treatment was begun being about four days. This was the average whether treated early or late. The largest number of his cases followed mastoidectomies and nose and throat operations, and it was interesting to note that the healing of the wound was not in any way delayed. It seemed to him as though healing took place quicker. In using the leucocytic extract no anaphylactic symptoms were at any time noted. There was no local reaction other than the slight pain due to the needle. There were no untoward symptoms that could be traced to the use of the extract itself.

Dr. Duncan MacPherson said that his experience with the leucocytic extract was confined entirely to clinical observations, and that in not a large number of cases. Many of his friends had used it, and all seemed to be satisfied that this was the best method of treating certain infections, especially erysipelas. He reported the case of a doctor who came to him for treatment for erysipelas. He had a temperature ranging from 103° to 105° F. The leucocytic extract was injected by Dr. Dwyer and the temperature promptly fell to 99°. Until recovery took place the temperature was never above 99°. Just before using a second injection of the extract the erysipelas commenced to spread from the original area and it was believed that it might spread over the head the second time. The use of the extract arrested its spread. One objection to the use of the serum was the pain that resulted, probably from the pressure at the site of injection. In the case reported the doctor was perfectly willing to stand the pain. It was desirable to use the injections early, and not wait until the patient became moribund. So far as the systemic effects were concerned, the use of the extract seemed to be perfectly harmless.

Dr. William W. Lang reported a case of pneumonia, the severest case he ever saw that got well. The patient was a nurse, thirty years old. The family, previous and personal, histories were practically negative except that he always had a rapid pulse, ranging from 100 to 110. He was admitted to the hospital with pneumonia of the right lower lobe; the pneumococci were obtained in pure cultures. The infection seemed to be a mild one and the toxic symptoms were not severe. However, the patient rapidly grew worse, and three days after admission there was consolidation of right lower and right upper lobes, with partial consolidation of the right middle lobe. Low down over the posterior portion of the left lung there were marked signs of consolidation. There were moist râles over the right lung. This patient was practically carrying on respiration with about one-half of the left lung. There was marked cyanosis and he was very toxic, and in the so-called typhoid state. Very vigorous stimulation was necessary and inhalations of oxygen were given. On Friday morning, five days after admission, he was not expected to live twenty-four hours. It was then suggested that the leucocytic extract be employed. He did not succeed in giving the first injection until Saturday night, and then improvement took place. The condition of this patient was certainly grave; on Thursday his temperature was 105°, pulse 160, and respiration 65. The first injection of the extract was given Saturday night at 6 o'clock; this was six days after admission, when the patient was in a very critical condition. After the injection the pulse promptly fell. A second injection was given six hours later, and this resulted in a still further fall. The following morning the change in the patient's condition was exceedingly striking. The cyanosis had disappeared. He was breathing as rapidly as before, but the respirations were deeper. The mental condition was much improved, and he was much more alert. A third injection was given, and from then on there was an uneventful recovery.

Dr. Philip D. Kerrison said he had observed one case treated with the leucocytic extract. Several years ago Dr. Whiting reported many cases of erysipelas which complicated mastoid operations, all of which were exceedingly virulent and dangerous. Personally, Dr. Kerrison had not met with such cases. At the Willard Parker Hospital all such cases seemed to do well. The case he wished to report, however, seemed to be of the type Dr. Whiting

had mentioned. The patient was a nurse, a young woman, who had been operated on by Dr. Harris for accessory sinus disease of the nose. An acute mastoiditis developed and the patient became very ill. She was prepared for operation. The temperature was 102° F. The mastoid was opened and revealed a very severe hemorrhagic inflammation. The next morning the temperature was 104°, and it was thought that this was a postoperative temperature. In the afternoon it rose to 105° Then the dressings were removed and there was found a typical case of erysipelas. The usual dressings were applied for this. The next day the temperature remained the same but the inflammation was rapidly spreading over the face. The temperature ranged from 104° to 105° and the pulse ranged from 120 to 128. The patient was exceedingly ill. From day to day the inflammation spread, the temperature remained high, and pulse was very rapid. The condition was very alarming. Then the injections of the leucocytic extract were begun and the temperature almost at once fell and the pulse went to 86; the inflammation ceased to spread and the extract seemed to exert spectacular control.

Dr. Dwyer said that the leucocytic extract did not seem to hasten the resolution at all, but it did seem to influence the toxic symptoms; the respirations would keep up. He had seen seven deaths from erysipelas since last summer.

The Segregation and Education of Children Affected with Ring Worm of the Scalp.—Dr. Udo J. Wile read this paper. (See page 910.)

Dr. George Henry Fox said that he agreed with all that had been said, and laid stress upon the fact that ring worm of the scalp was one of the most important diseases of childhood that they were called upon to treat, and that, perhaps, there was no affection of childhood so important and so apt to be overlooked and minimized as ring worm in children. The prevalent methods of treatment were not at all satisfactory. Ring worm often passed unrecognized and produced much harm; but all made mistakes in diagnosis. On the other hand, when a physician was sure that he had to deal with a case of ring worm, and he knew that this affection was an extremely obstinate one and had a tendency to spread and infect other children, especially among that class of people in the community ill able to bear the expense involved, when such a physician looked wise and wrote a prescription for a parasitic ointment and sent the child back to school under the mistaken impression that the disease was cured, it seemed to Dr. Fox that something more than a mistake was made. The disease itself was obscured by such a treatment and the patient might infect others in the school. Ring worm of the scalp should be considered as an avoidable disease. The Board of Health of the City of New York had done a great deal to prevent the spread of disease by careful inspection in the schools and the dissemination of literature. He was glad to know the Health Board was going to do more, and upon the lines laid down by Dr. Wile in his paper. To send a child from school to the home was the proper thing to do, but it certainly was an injustice to the child, as it interfered with his education. The newer treatment of ring worm of the scalp was eminently successful. The *x*-ray treatment was by all means the best and perhaps the only certain method of treatment they had. But the *x*-ray was a double-edged remedy. It would do good in these cases and it would do harm except in the hands of an expert. Dr. Fox had seen permanent apopecia occur from the over-exposure of the *x*-ray. With regard to the segregation of those affected with ring worm in the schools the idea of Dr. Dwyer was a fine one, but the trouble was in the expense involved. Some part of the school building might be set apart, or some class room, where these children could be kept during the time of treatment. There was no other plan not involving much expense and trouble that could be carried out by the Health Department. The appointment of one or two medical inspectors who were conversant with the modern treatment of ring worm by means of the *x*-ray might be advisable. They should be so located that these children could be sent to them for treatment. This was the only plan Dr. Fox could think of to eradicate the disease from the homes, the schools, the asylums and other places in this city.

Dr. Charles Herrman said that Dr. Wile had brought up a very important subject for discussion, for what was true of ring worm was also true with certain modifications of several other contagious diseases of the skin and of the eye. As to the number of cases of ring worm in the public schools of New York he agreed with Dr. Wile that the statistics were not reliable as to the *total number*. However, in 1909 there were 7,788 cases found, and in 1910 only 4,505. As the examinations were made by the same corps of medical inspectors under the same conditions, it is safe to say that the number had diminished. Only a very small percentage of these went to the dispensaries, probably less than 10 per cent. The increase in the number seen at the dispensaries was due to the fact that the school nurses were inducing a larger percentage to go there for treatment. The diagnosis was often difficult, but in all doubtful cases the inspector referred the case to the private physician or to the dermatological department of the dispensary. Dr. Herrman was of the opinion that the contagious skin diseases were not so easily spread as was often supposed, especially among children who were cleanly. In the public schools there was no danger (as there was in asylums and other institutions) from the promiscuous use of combs, brushes and towels. Teachers could help very much by inculcating habits of cleanliness among the children. Although the plan suggested by Dr. Wile was the ideal one, there were many difficulties. The City of New York was so large that a very large number of special schools would be necessary in order that the children would not be compelled to travel long distances. Several classes for children of different ages would be required, necessitating the employment of many more teachers. The *x*-ray outfit and expert radiographist in each school would still further increase the expense. What applied to ring worm of the scalp applied with certain modifications to fevers, scabies, pediculosis, and trachoma. It would be practically impossible to provide special classes for all of these. It seemed to Dr. Herrman that we could get along pretty well with our present method. The worst cases could be excluded until in the opinion of the dermatologist they could return to school. The clinics could treat a large number thoroughly, possibly with the *x*-ray. Most of the children could, while under treatment, continue attendance at school. They could wear a tight-fitting linen cap and be seated in one corner of the room separated from the others. If a child was simply excluded from school it might still infect other children on the street. If it attended school the nurse could see to it that it was regularly treated.

Mr. William O'Shea, District Superintendent of Schools, Board of Education, said he believed that the people of the City of New York, more than any other section of the country, had reason to be grateful to the medical profession in the city, as well as to the Department of Health, for the time and study they had given in the matter of the prevention and cure of contagious and infectious diseases. Bacteriological investigations had disclosed the causes; the causes once determined had made clear, so far as many diseases were concerned, the means of avoiding them. Laymen, as well as members of the medical fraternity, appreciated the results of the labors

of the medical men, as shown in modern sanitary conditions, improved hospital conditions, better management of the sick room, and the more intelligent enlightenment of the public in combating contagious and infectious diseases. The preventive and curative methods in cases arising in the public schools of this city had improved within recent years. Each succeeding year they had a more effective system as the result of the study, supervision, and control of contagious and infectious diseases. The methods of to-day were immeasurably better than they were ten years ago. If they were to judge by this improvement, then the next decade would show the children of the schools placed under such auspices which would not only reduce to the minimum the chances of infection and contagion but make it almost impossible for the children to suffer from such handicaps as mentioned in the paper. Even if they had to resort for this purpose to the enactment of new laws which compelled parents to bring their children to the family physician or to the public dispensaries, children who were suffering from neglected medical attention, it would result in good. The Board of Education was doing a great deal for the improvement of the child's welfare. In addition to the course of instruction the board had opened up classes for the blind, for the deaf, for the backward, and for the mental defectives; each class was equipped with modern appliances. The board had segregated the anemic and furnished them with open-air classrooms, given them nutritious food, etc. The board had also segregated the tuberculous children. The results warranted this innovation. The Board of Education was always willing and ready to adopt any measures suggested by competent authorities that aimed at the improvement and benefit of the children in the schools. If they would look upon this matter in a sensible and broad-minded way a child in the schools ran no more risk than when he was on the street: a child with ring worm, trachoma, or pediculosis in the school must pass the scrutiny of the health officer of the school as well as that of the nurse; when he has passed the supervision of the principal, the teacher, the physician and the nurse he then had run the gauntlet.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

BOARD OF MEDICAL EXAMINERS OF THE STATE OF WASHINGTON.

January 3-7, 1911.

(One day of the examination was devoted to a practical clinical test at the hospital and to the use of the microscope.)

ANATOMY.

(Answer ten questions only.)

1. Describe the stomach, give its average size, attachments, regional location, gross structure, blood and nerve supply.
2. Give origin, insertion, action and nerve supply of one of the following muscles: Deltoid, soleus, or quadratus lumborum.
3. Give boundaries of Scarpa's triangle.
4. Describe the popliteal space, give its boundaries and contents.
5. What are the lymphatics? Describe fully.
6. Give blood-supply of the leg. Mention venous compensation.
7. Name veins that compose the portal circulation, with a description of any one of its branches.
8. Describe the clavicle, naming the muscles and ligaments attached to it.
9. Name and describe the arteries and veins of the rectum.
10. Give the surface topography of the appendix vermiformis, gall bladder, apex of heart and apices of lungs.
11. Mention divisions of the alimentary canal.
12. Name, give action and nerve supply of the muscles that move the eyeball.

HISTOLOGY.

(Twelve questions—answer ten.)

1. What is meant by the term connective tissue? Give the three great groups of connective tissue. Are they all developed from the same elements?
2. What is an Haversian system? An Haversian canal? What are lamellæ? Are the lacunæ filled during life with a nucleated cell? If so, what purpose do they serve?
3. Of what is the white substance of the cord composed? What is the neuroglia?
4. Describe how nerve fiber joins voluntary muscle fiber.
5. What is the average size of a capillary? Where are the smallest found? Where are the largest found?
6. Give the minute anatomy of a lymphatic gland. Give the course of the lymph stream from afferent vessel to efferent.
7. Describe the cutis vera. Give the two layers of the fibroareolar tissue forming the framework of the cutis.
8. What is a serous membrane supported by a thin fibrous layer called? Give an example. What cells line the entire surface of serous membranes?
9. To what structure of the skin is the corium analogous?
10. What are the essential parts of a secreting gland? Give a drawing of a racemose gland in its simplest form. In what organs are found the best examples of the compound tubular glands?
11. Give the two kinds of gastric follicles. With what kind of epithelium are they lined?
12. In what part of the kidney do the tubuli uriniferi commence? Where do they terminate? Describe a Malpighian tuft.

PHYSIOLOGY.

1. What are the active elements in the gastric secretion and what are the functions of each?
2. What are the constituents of the blood and what are the functions of each?
3. What is the medulla oblongata and what are its functions?
4. What do you mean by the sympathetic nervous system, what is its function and what are its leading subdivisions?
5. Trace the passage of sound from the external ear to the central nervous system.
6. What do you mean by the motor area in the brain, where is it located and what is its function?
7. Explain the mechanism of respiration.
8. What do you understand by the vasomotor system, give its function, nerve supply, and center of control.
9. Explain carefully the function of the skin.
10. What are the functions of the liver?
11. What is the colon, what is its function and what part does it take in digestion?
12. Name all the glands concerned in the process of digestion.

CHEMISTRY.

1. Define (*a*) an atom, (*b*) a molecule, (*c*) atomic weight, (*d*) equivalent weight.
2. Define an acid. What is the essential element in all acids?
3. Define (*a*) qualitative analysis, (*b*) a chemical reagent.
4. What is (*a*) a normal salt, (*b*) an acid salt, (*c*) a double salt?
5. Give the chemical name and formula of lunar caustic.
6. Give the chemical name and formula of (*a*) calomel, (*b*) corrosive sublimate and give a simple test that will distinguish one from the other.
7. Name some of the more common abnormal chemical constituents of the urine.
8. Give two tests for albumin in the urine, describing the process and the reaction.
9. Give two tests for sugar in the urine, describing process and reaction.
10. Give a chemical test for blood in the urine, describing process and reaction.
11. In what respect does human milk differ from cow's milk?
12. A man takes a poisonous dose of arsenic (As_2O_3) and is given a mixture of ferric sulphate ($Fe_2(SO_4)_3$) with magnesium oxide (MgO) and water. Why given? Illustrate by chemical formula.

TOXICOLOGY.

(Twelve questions—answer ten.)

1. What alkaline antidotes are most likely to be at hand in a case of emergency poisoning?
2. What are the first evidences of the toxic effects of strychnine? In fatal cases to what is death generally due? Distinguish from tetanus.
3. Give the symptoms of aconite poisoning.
4. In case of poisoning, the nature of the poison being unknown, how should the case be handled?
5. Give symptoms of prussic acid poisoning and the appearance of the body after death from such poisoning.
6. Give the symptoms of chronic lead poisoning.
7. Give the characteristic phenomena of carbolic acid poisoning and the initial symptom of poisoning from the use of the acid externally.
8. Are the changes in the organs after death from phosphorus poisoning due to the direct action of the drug or to disturbance of tissue metabolism?
9. Give the symptoms of acute arsenical poisoning; also after death the macroscopic changes apparent in stomach and upper bowels.
10. Give the symptoms of chronic mercurial poisoning.
11. What is the most important irritant poison of vegetable origin? For what is it oftentimes mistaken?
12. Give symptoms caused by eating poisonous fungi. In fatal cases how soon does death usually occur?

PATHOLOGY.

1. Give concise definition of inflammation and name the cardinal symptoms of same.
2. Define: (*a*) Metaplasia, (*b*) hyperplasia, (*c*) hypertrophy, (*d*) sclerosis.
3. Give the pathology of lobar pneumonia.
4. Differentiate: (*a*) Fatty degeneration, (*b*) fatty infiltration, (*c*) fat necrosis.
5. What is: (*a*) Gangrene, (*b*) necrosis, (*c*) ulceration?
6. Give the pathology of typhoid fever (intestinal lesions).
7. Differentiate resolution from regeneration; (*b*) example of each.
8. Classify tumors.
9. (*a*) What is a tumor? (*b*) What are the signs of malignant tumors? (*c*) What type of cells is the (*a*) sarcoma composed of; (*b*) carcinoma?
10. What is edema? (*b*) Name five diseases which are a localized edema.

GENERAL DIAGNOSIS.

(Answer ten questions only.)

1. Give periods of incubation and eruption of the exanthemata.
2. Differentiate aortic stenosis and aortic insufficiency.
3. What casts are found in the urine and give clinical significance of each.
4. Give causes, symptoms and sequelæ of otitis media.
5. Give differential diagnosis between dislocation of head of the femur and fracture of the neck of the femur.
6. Name three varieties of venereal disease and give the symptomatology of each.
7. Give diagnostic points of pulmonary tuberculosis in incipient stage.
8. Give causes, symptoms, and prognosis of endocarditis and differentiate from pericarditis.
9. Diagnose a case of typhoid fever. What is its exciting cause and by what means does the disease find lodgment?
10. Give differential diagnosis between pleuritic and pericardial effusions.
11. Describe principal varieties of talipes.
12. Give diagnostic symptomatology of a case of anterior poliomyelitis.

BACTERIOLOGY.

1. Give the scope of bacteriology, classify bacteria, and give methods of studying them.
2. Give the structures and describe the mode of development and growth of bacteria.
3. Give the effects of physical and chemical agents on bacteria.
4. Give routes of infections, define bacteremia, toxemia, mixed infection, and secondary infection.
5. What are spores? What are their characteristics? Are all bacteria spore forming?
6. Describe some of the ways in which infections may be transmitted.
7. Name some of the defenses of the body against pathogenic bacteria and describe how they are operative.
8. Define anaerobes and give examples.
9. Name some of the varieties, method of staining, state in what affections most commonly found, and give other distinguishing characteristics of staphylococci, streptococci, and gonococci.
10. Give characteristics and subdivisions of the colon-typhoid group of bacilli.
11. What are spirilla and protozoa? Give some of the common and well known forms of each of the pathogenic type.
12. What are the sources of bacteria in milk? Is freshly drawn milk always sterile? What is the largest number of bacteria per cubic centimeter permissible in milk offered for consumption?

HYGIENE.

1. Define hygiene, contagion, infection, epidemic, sporadic, endemic, pandemic, fomites, mediate, intermediate, atmospheric, and telluric.
2. Given a case of scarlet fever, mention step by step your procedure for the protection of the family and community.
3. Give the source and physical properties of good water; name three diseases of bacterial origin which polluted water may cause and measures of purification to be used.
4. What precautions should be taken at our seaports to prevent an outbreak of bubonic plague and cholera?
5. Give the composition, source and means of preservation of wholesome milk. What are the common adulterations and contaminations of milk? What antiscorbutic measures would you advise for a bottle-fed baby?
6. In an epidemic of typhoid fever describe fully how you would go about it to discover the source of infection and stamp it out.
7. Give the detention period after exposure to smallpox, scarlet fever, diphtheria, measles, cholera, bubonic plague, typhoid, and yellow fever.
9. With a case of tuberculosis in a family, write fully your directions to the patient and to the other members of the household for their protection.
10. Name the best agents for disinfection of the sick room, clothing, bedding, person, and excreta of a patient with a contagious or infectious disease.
11. Give the accredited causes of malaria and yellow fever and tell what measures afford the best means of protection from infection.
12. Give the rules which should govern the drinking water, heat, light, ventilation, and sewerage of a modern school house.

OBSTETRICS.

1. Name the bones constituting the pelvis and give the pelvic diameters.
2. What are the diagnostic signs of pregnancy? Etiology and symptomatology of eclampsia? Etiology of phlegmasia alba dolens? of pruritis vulvæ? of morning sickness?
3. What changes take place in the blood and urine in pregnancy?
4. Differentiate between a tubal pregnancy and acute salpingitis. Between placenta prævia and fibroid tumor.
5. What are the symptoms of threatened abortion? What are the indications for the induction of abortion?
6. Describe in detail the progress of a normal labor from the first labor pains until the delivery of the afterbirth.
7. Give indications for use of forceps. Describe fully the manner of application.
8. How would you diagnose a breech presentation? Give method of delivery of the after-coming head.
9. Give methods of inducing the new-born child to breathe.
10. What symptoms would lead you to suspect puerperal infection? What is the prognosis?
11. What is ophthalmia neonatorum? To what is it due? What are the symptoms and dangers?
12. Give directions for the preparation of the lying-in chamber and the expectant mother.

GYNECOLOGY.

1. What is subinvolution? Give its symptoms and complications.
2. Explain the anatomical condition which results from laceration of the pelvic floor down to the sphincter ani and give the sequence of events which follows.
3. Diagnose between pelvic cellulitis and primary purulent peritonitis.
4. Diagnose between a fibroid and an ovarian cyst.
5. What is the normal position of the uterus? Classify the abnormal positions.
6. Give the cause, history, and symptoms of a ruptured

ectopic pregnancy at about six weeks and diagnose from a miscarriage at the same time.

7. What is leucorrhea, what is its cause, what glands are involved and what germ is present?

8. Describe a carcinoma of the cervix, giving its symptoms, period of life, and cause of death.

9. What is a urethral caruncle? Describe its appearance and give its symptoms.

10. What is Bartholinitis? What is the germ? Give symptoms and prognosis.

11. Give a careful diagnosis between appendicitis and a right-sided oophoritis.

12. What is the climacteric? Describe carefully the changes which take place in the pelvis at that time and subsequently.

ANSWERS TO STATE BOARD EXAMINATION QUESTIONS.

Board of Medical Examiners of the State of Washington.

January 3-7, 1911.

ANATOMY.

1. See Cunningham's "Anatomy" (1910), page 1050; or Gray's "Anatomy" (1908), page 1277.

2. See Cunningham's "Anatomy" (1910), pages 328, 378, and 430; or Gray's "Anatomy" (1908), pages 472, 538 and 451.

3. *Scarpa's triangle* is bounded *above* by Poupart's ligament; *externally* by the Sartorius; and *internally* by the inner margin of the Adductor longus; its *apex* is formed by the junction of the Adductor longus and Sartorius. The *floor* is formed, from without inward, by the Iliacus, Psoas, Pectineus, Adductor brevis, and Adductor longus.

4. The Popliteal Space is *bounded: Above, and externally* by the Biceps; *above, and internally* by the Semimembranosus and Semitendinosus; *below, and externally* by the Plantaris and external head of the Gastrocnemius; *below, and internally* by the inner head of the Gastrocnemius. *Contents:* Popliteal vessels with branches, external saphenous vein, external and internal popliteal nerves, small sciatic nerve, lymphatic glands, and loose areolar tissue.

5. See Cunningham's "Anatomy" (1910), page 904; or Gray's "Anatomy" (1908), page 772.

6. See Cunningham's "Anatomy" (1910), pages 863 and 898; or Gray's "Anatomy" (1908), pages 707 and 756.

7. See Cunningham's "Anatomy" (1910), page 901; or Gray's "Anatomy" (1908), page 768.

8. The *clavicle* forms the anterior part of the shoulder girdle; it articulates internally with the first part of the sternum, and externally with the acromion process of the scapula. It is broad and flattened at its outer end, and thick and rounded at the inner end. It consists of a double curve, the outer part is concave forward, the inner part convex forward. The bone has two surfaces, superior and inferior, and two borders, anterior and posterior. On the under surface are the conoid tubercle, a groove for the subclavius, a rough impression for the rhomboid ligament. *Muscles attached to it* are: Deltoid, trapezius, pectoralis major, subclavius, sternomastoid, and sternohyoid. *Ligaments attached to it* are: Interclavicular, rhomboid, conoid, trapezoid, and capsular (of sternoclavicular and acromioclavicular articulations).

9. The arteries and veins of the rectum are the superior hemorrhoidal, middle hemorrhoidal, and inferior hemorrhoidal. See Cunningham's "Anatomy" (1910), pages 848, 851, 854, and 866; or Gray's "Anatomy" (1908), pages 680, 688, 691, and 760.

10. *Appendix vermiformis* usually under McBurney's point (on anterior abdominal wall, midway between umbilicus and anterior superior spine of ilium on right side), and pointing upwards and inwards. *Gall-bladder*, at under surface of liver and outer border of right rectus abdominis muscle. *Apex of heart*, at fifth left intercostal space, about 3½ inches from median line of body. *Apices of lungs*, in neck, above clavicle, behind the interval between the two heads of sterno-cleido mastoid muscle, generally extending for about one inch above the clavicle.

11. The *divisions of the alimentary canal* are: Mouth, pharynx, esophagus, stomach, small intestine (duodenum, jejunum, and ileum), and large intestine (cecum, colon, and rectum).

12. See Cunningham's "Anatomy" (1910), page 401; or Gray's "Anatomy" (1908), page 375.

HISTOLOGY.

1. "By the name of *'connective tissues'* we designate a variety of tissues which have in common with one another that they are developed from the same embryonic elements; that they all serve as supporting tissue or connecting substance for nervous, muscular, glandular, and vascular tissues; that they are capable of taking one another's place in the different classes of animals; that in the embryo and in the growing normal and morbid condition one may be changed into the other; that in the adult they gradually shade off one into the other; and that they yield allied chemical products."—(Klein's *Histology.*)

The three great groups are: (4) Fibrous connective tissue; (2) cartilage; and (3) bone (and dentine). They are all developed from the same embryonic elements, the mesoderm.

2. See Cunningham's "Anatomy" (1909), page 72; or Gray's "Anatomy" (1908), pages 35, 38, and 39.

3. See Cunningham's "Anatomy" (1909), pages 451, 461, and 465; or Gray's "Anatomy" (1908), pages 848 and 832.

4. "The motor endings of the voluntary muscles are chiefly from myelinated fibers. After piercing the epimysium the nerve follows the septa to the primary bundles and breaks up into fibers of which each muscle receives one; no doubt one nerve fiber supplies many muscle fibers. The neurilemma and myelin sheath of the nerve fibers upon passing through the sarcolemma blend with it and the axis cylinder breaks into fibrillæ, each of which forms a number of bulbous enlargements that pass to a sole-plate. This sole-plate consists of a mass of nucleated, granular protoplasm, and with the bulbous nerve masses constitutes the end-plate."—(Radasch's *Histology.*)

5. The average diameter of a capillary is about 1/3000 to 1/2000 of an inch. The *smallest* capillaries are found in the central nervous system; the *largest* in bone-marrow.

6. See Cunningham's "Anatomy" (1909), page 905; or Gray's "Anatomy" (1908), page 774.

7 and 9. See Cunningham's "Anatomy" (1909), page 773; or Gray's "Anatomy" (1908), page 1190.

8. Serous membrane consists of endothelium upon a layer of fibrous tissue. *Example:* Peritoneum. Endothelial cells line the surface of serous membranes.

Possibly the examiner is thinking of synovial membranes, found in joints and around tendons.

10. See Cunningham's "Anatomy" (1909), page 1008.

11. Pyloric and cardiac glands: they are lined with cubical and columnar epithelial cells.

12. See Cunningham's "Anatomy" (1909), page 1139; or Gray's "Anatomy" (1908), page 1426.

PHYSIOLOGY.

1. The active elements in the gastric secretion are pepsin and hydrochloric acid. These two together split up proteids into proteoses and peptones. The pepsin alone cannot do this; a small amount of hydrochloric must be present. There is also a milk-curdling ferment which can act without hydrochloric acid. The hydrochloric acid is also a powerful disinfectant and germicide, and kills many bacteria that are ingested with the food.

2. Constituents of the Blood. *Plasma:* Water and solids; the latter containing proteids, extractives, fats, and salts of sodium, potassium, and calcium. *Corpuscles:* Water and solids; the latter containing hemoglobin, globulin, lecithin, cholesterin, iron, and salts of sodium, potassium, magnesium, and calcium.

Functions of the blood: The *red blood cells* carry oxygen from the lungs to the tissues. The *white blood cells:* (1) Serve as a protection to the body from the incursions of pathogenic micro-organisms; (2) take some part in the process of the coagulation of the blood; (3) aid in the absorption of fats and peptones from the intestine, and (4) help to maintain the proper proteid content of the blood plasma. The function of the *platelets* is not determined; it is possible that they take some part in the coagulation of the blood. The *plasma* conveys nutriment to the tissues; it holds in solution the carbon dioxide and water which it receives from the tissues, and takes them to be eliminated by the lungs, kidneys, and skin; it also holds in solution urea and other nitrogenous substances that are taken to and excreted by the liver or kidneys.

3. The medulla oblongata is a column of nerve substance (both white and gray) forming the lowest part of the brain, and connecting below with the spinal cord. Its *functions* are: (1) To conduct nerve impulses or impressions from the spinal cord to the cerebrum, and from the brain to the spinal cord; (2) it also contains collections of gray matter which serve as special centers for the following functions or actions: Respiration, salivary secretion, mastication; sucking, deglutition, speech production, facial expression; also the cardiac and vasomotor centers.

4. See Cunningham's "Anatomy" (1909), page 703; or Gray's "Anatomy" (1908), page 1077.

Functions: "It may safely be said that the sympathetic system has, to a great extent, a controlling influence over the secretion of most of the glands, the lacrymal, the salivary, the sweat glands, the glands of the stomach and intestines, the liver, the kidney, etc.; that it presides over the circulation by regulating the caliber of the blood-vessels and the action of the heart; that it influences respiration; and, finally, that all involuntary muscles, those of the digestive apparatus, of the genitourinary system, of the hair follicles (pilomotor nerves), are under its control to such extent that, for instance, in certain mammalains the bladder still continues to fulfill its function for weeks after all the cerebrospinal motor nerves leading to it have been severed. In short, we find that all vegetative life of the organism is, to a greater or less extent, under the control of the sympathetic system. Therefore it may properly be called the vegetative nerve system *par excellence*."—(*Reference Handbook of the Medical Sciences.*)

5. "The waves of sound are gathered together by the pinna and external auditory meatus, and conveyed to the membrana tympani. This membrane, made tense or lax by the action of the tensor tympani and laxator tympani muscles, is enabled to receive sound waves of either high or low pitch. The vibrations are conducted across the middle ear by a chain of bones to the foramen ovale, and by the column of air of the tympanum to the foramen rotundum, which is closed by the second membrana tympani, the pressure of the air in the tympanum being regulated by the Eustachian tube. The internal ear finally receives the vibrations, which excite vibrations successively in the perilymph, the walls of the membranous labyrinth, the endolymph, and, lastly, the terminal filaments of the auditory nerve, by which they are conveyed to the brain."—(Brubaker's *Physiology.*)

6. The motor area in the brain is that portion of the cerebral cortex situated immediately in front of the fissure of Rolando. It is the part concerned with the functions of muscular movement. At the upper part of this area are the parts connected with the movement of the lower extremities; then from above downward are located the centers for the movements of the trunk, shoulders, arms, wrists, fingers, face, lips, tongue, larynx, and pharynx.

7. See Cunningham's "Anatomy" (1909), page 419; or Gray's "Anatomy" (1908), page 434.

8. The vasomotor system is that part of the sympathetic nervous system which is concerned with the regulation of the caliber of the blood-vessels. Its center is in the medulla. It consists of two sets of fibers, the one, *vasodilators*, increasing the caliber; the other, *vasoconstrictors* diminishing the caliber.

9. The *functions of the skin* are: Protection, excretion, secretion, regulation of the body temperature, absorption, sensation, special sense of touch, respiration.

10. The *functions of the liver* are: (1) The secretion of bile, (2) the formation of glycogen, (3) the formation of urea and uric acid, (4) the manufacture of heat, and (5) the conversion of poisonous and harmful into inert material.

11. The colon is that part of the large intestine which begins at the cecum and ends at the sigmoid flexure. No new digestive action takes place in the colon, but such digestion as has already commenced in the stomach and small intestine may be continued here; there is also some absorption here. The refuse is separated and prepared for expulsion.

12. Salivary (parotid, submaxillary, sublingual), gastric (peptic and pyloric), intestinal, liver, and pancreas.

CHEMISTRY.

1. An *atom* is the smallest part of an element which can enter or leave a chemical reaction. A *molecule* is the smallest part of a substance (element or compound) which can exist free. *Atomic weight* is the weight of an atom of an element as compared with the weight of an atom of hydrogen. *Equivalent weight* is the weight of an element capable of combining with a unit weight of hydrogen; it is the atomic weight of the element divided by its valence.

2. *An acid* is a compound of hydrogen with an electronegative element or radical, part or all of which hydrogen it can part with in exchange for an electro-positive element without the formation of a base. Hydrogen is the essential element in all acids.

3. *Qualitative analysis* is the determination of the nature of the elements which compose a substance. A *chemical reagent* is a substance used to produce a chemical reaction.

4. A *normal salt* is a salt formed by replacing all of the available hydrogen of the acid; as $K_2C_4H_4O_6$. An *acid salt* is one in which part only of the available hydrogen has been replaced, as $KHC_4H_4O_6$. A *double salt* is one that is formed by different elements or radicals replacing the available hydrogen of the acid, as $KNaC_4H_4O_6$.

5. Silver nitrate, $AgNO_3$.

6. *Calomel,* mercurous chloride, Hg_2Cl_2. *Corrosive sublimate,* mercuric chloride, $HgCl_2$. Calomel is insoluble in water; corrosive sublimate is soluble in water.

7. Albumin, blood, bile, glucose, pus, acetone.

8. *Two reliable tests for albumin in the urine:* "The urine must be perfectly clear. If not so, it is to be filtered, and if this does not render it transparent, it is to be treated with a few drops of magnesia mixture and again filtered."

I.—*The heat test:* "The reaction is first observed. If it be acid, the urine is simply heated to near the boiling point. If the urine be neutral or alkaline, it is rendered *faintly* acid by the addition of dilute acetic acid, and heated. If albumin be present, a coagulum is formed, varying in quantity from a faint cloudiness to entire solidification, according to the quantity of albumin present. The coagulum is not redissolved upon the addition of HNO_3."

II.—*Heller's modification of the nitric acid test:* "Place in a test-tube a layer of HNO_3 about 2 centim. in thickness; then, with a pipette, carefully float upon the surface of this a layer of the urine in such a manner that the liquids do not mix. If albumin be present, a cloudy ring appears *at* the point of juncture of the two layers, the borders of the cloud being sharply defined. A cloudy ring may be formed by the presence of an excess of urates, but in this case it is not *at,* but *above,* the point of junction of the layers, and its upper border is not sharply defined, but fades off gradually."—(Witthaus' *Essentials of Chemistry.*)

9. *Two reliable tests for sugar in the urine:* The urine should first be tested for albumin. If this be present, it should be removed by heating the urine to near the boiling point and filtering from the coagulum.

(1) *Fehling's test:* Place in a test-tube a few c.c. of the liquid prepared as stated below and boil; no reddish tinge should be observable, even after five minutes' repose. Add the liquid under examination gradually, and boil after each addition. In the presence of sugar a yellow or red precipitate is formed. In the presence of *traces* of glucose, only a small amount of precipitate is produced, which adheres to the glass, and is best seen when the blue liquid is poured out.

[The reagent must be kept in two solutions, which are to be mixed immediately before use. Solution I consists of 34.653 gms. of crystallized $CuSO_4$, dissolved in water to 500 c.c.; and Solution II of 130 gms. of Rochelle salt dissolved to 500 c.c. in NaHO solution of sp. gr. 1.12. When required for use equal volumes of the two solutions are mixed, and the mixture diluted with four volumes of water.]

(2) *Boettger's test:* Render the urine strongly alkaline by addition of Na_2CO_3. Divide about 6 c.c. of the alkaline liquid in two test-tubes. To one test-tube add a very minute quantity of powdered subnitrate of bismuth, to the other as much powdered litharge. Boil the contents of both tubes. The presence of glucose is indicated by a dark or black color of the bismuth powder, the litharge retaining its natural color.—(From Witthaus' *Essentials of Chemistry.*)

10. *Blood:* To the urine add a solution of potassium hydroxide to distinct alkaline reaction; heat nearly to boiling (do not boil). A red precipitate is produced.

11. Human milk contains less albumin and more sugar than cow's milk.

12. The ferric sulphate, magnesium oxide, and water make ferric hydroxide (which is the antidote for arsenic):

$$Fe_2(SO_4)_3 + 3MgO + 3H_2O = 3MgSO_4 + Fe_2(OH)_6$$

This latter (ferric hydroxide) acts as follows:

$$As_2O_3 + 2Fe_2(OH)_6 = Fe(OH)_2 + 5H_2O + Fe_3(AsO_4)_2$$

TOXICOLOGY.

1. Milk, magnesia, sodium carbonate, potash, ammonia, soda.

2. The *symptoms of strychnine poisoning* are as follows: "Strychnine produces a sense of suffocation, thirst, tetanic spasms, usually opisthotonos, sometimes emprosthotonos, occasionally vomiting, contraction of the pupils during the spasms, and death, either by asphyxia during a paroxysm, or by exhaustion during a remission. The symptoms appear in from a few minutes to an hour after taking the poison, usually in less than twenty minutes; and death in from five minutes to six hours, usually within two hours." (Witthaus' *Essentials of Chemistry.*)

In *tetanus,* the onset is gradual, is apt to begin with

trismus, swallowing is difficult or impossible, the condition is persistent, consciousness is dulled or lost, and there is history of a wound or injury. In *strychnine poisoning* the onset is more sudden, the muscles of the jaw and neck are generally the last to be affected, there are marked remissions with muscular relaxation, consciousness is retained, and there is no history of a wound or injury.

3. *Symptoms of aconite poisoning* usually manifest themselves within a few minutes; sometimes are delayed for an hour. There is numbness and tingling, first of the mouth and fauces, later becoming general. There is a sense of dryness and of constriction in the throat. Persistent vomiting usually occurs, but is absent in some cases. There is diminished sensibility, with numbness, great muscular feebleness, giddiness, loss of speech, irregularity and failure of the heart's action. Death may result from shock if a large does of the alkaloid be taken, but more usually it is by syncope.

4. The first thing to do is to remove as much as possible of the unabsorbed poison, give an emetic (apomorphin hydrochlorid), and also wash out the stomach except when a corrosive has been taken. White of egg and water may be given. Then combat symptoms as they arise, try to prevent shock; artificial respiration, warmth, stimulants, etc., may be indicated.

5. Prussic acid poisoning. *Symptoms:* "Its action is always rapid. Relatively small doses cause an immediate sense of constriction of the throat, followed in one or two minutes by sense of pressure in the head, vertigo, confusion of intellect, and loss of muscular power. The pulse is quick, the respiration slow and stertorous. Tetanic convulsions and involuntary discharges of urine and feces occur, followed by paralysis. Death follows, in from two hours to two days, from asphyxia. When large doses are taken no subjective symptoms are observed. The patient loses consciousness in less than one minute. There is a short convulsive seizure, usually accompanied by evacuations of feces, after which the patient lies perfectly still, with no sign of life, save an almost imperceptible pulse and infrequent spasmodic respiratory efforts, in which inspiration is short and expiration protracted. Death follows in from five to twenty minutes."

Rigor mortis sets in early, putrefaction is rapid, the veins are distended, the left ventricle is empty, the right ventricle is full of dark uncoagulated blood. There is an odor of bitter almonds or peach kernels.

6. Chronic lead poisoning. *Symptoms:* Anemia, emaciation, depression, pain round the umbilicus, hard and retracted abdomen, constipation or clay colored evacuations, diminished urine, fetid breath, blue line on gums, wristdrop, numbness of hand, paralysis, vertigo.

7. *Symptoms of carbolic acid poisoning:* Buccal mucous membrane is whitened and hardened; vomiting; burning pain in mouth, esophagus, and stomach; pulse and body temperature are lowered; the pupils are contracted; collapse, and finally death. The urine may become dark.

8. Disturbances of tissue metabolism.

9. The *symptoms of acute arsenical poisoning:* "In acute cases the symptoms usually begin in from twenty to forty-five minutes. Nausea and faintness. Violent, burning pain in the stomach, which becomes more and more intense, and increases on pressure. Persisting and distressing vomiting of matters, sometimes brown or gray, or streaked with blood, or green (Paris green). Purging. More or less severe cramps in the lower extremities." (Witthaus' *Essentials of Chemistry.*)

The stomach and intestines are inflamed, and the mucous membrane torn and detached; particles of the poison may be found adherent.

10. *Symptoms of chronic mercurial poisoning:* Salivation, anorexia, languor, swollen gums, scanty urine, tremors, fetid breath, loose teeth, ulcerated mouth, necrosis of jaw, insomnia.

11. Probably oxalic acid, taken in mistake for Epsom salt (magnesium sulphate).

12. *Symptoms in poisoning from fungi:* Sudden onset, great prostration, cold perspiration, headache, fever, rapid and feeble pulse, pain in abdomen, diarrhea, cyanosis, urine scanty or suppressed and albuminous or bloody; stupor and delirium.

Death generally occurs in from eighteen hours to three or four days.

PATHOLOGY.

1. *Inflammation* is the name given to the series of changes occurring in a part as the result of injury, provided that the injury is not sufficient to at once destroy its vitality. *Symptoms* are: Redness, swelling, pain, heat, and disordered function.

2. *Metaplasia* is the change of one tissue into another (of the same histological group), as the conversion of cartilage into bone. *Hyperplasia* is increase in the size of a tissue or organ owing to an increase in the number or size of its cells. *Hypertrophy* is an increase in the size or tissue of an organ, independent of the general growth of the body. *Sclerosis* is the hardening of a part due to overgrowth of fibrous tissue or deposit of salts.

3. See French's "Practice of Medicine" (1910), page 154; or Osler's "Practice of Medicine" (1909), page 170.

4. In *fatty degeneration* the cell protoplasm of the cells affected is changed to fat. In *fatty infiltration,* fat is brought by the blood and deposited in the substance of certain cells. *Fat-necrosis* is a form of necrosis to which fatty tissues are liable; it is supposed to be due to pancreatic disease.

5. *Gangrene* is death in mass of a portion of the living body large enough to be visible. *Ulceration* is molecular death of a portion of the living body. *Necrosis* is death in mass of bone, or of parts below the surface.

6. See French's "Practice of Medicine" (1910), page 70; or Osler's "Practice of Medicine" (1909), page 65.

7. *Resolution* is the return of a part to the normal after some pathological process. *Regeneration* is the formation of new cells or tissues to take the place of those which have been destroyed. In the former case the part was not destroyed. *Example: Resolution* in pneumonia; the lung was inflamed, but not destroyed; *regeneration* in fractured bone.

8. *Tumors are classified as follows:*

I. Those derived from mesoblast:
   (*a*) *Benign:* Lipoma, fibroma, chondroma, osteoma, myxoma, myoma, neuroma, glioma, angioma, lymphangioma.
   (*b*) *Malignant:* Sarcoma.
II. Those derived from epiblast or hypoblast:
   (*a*) *Benign:* Adenoma, papilloma.
III. Cystic tumors.
IV. Teratomata.

9. (*a*) A *tumor* is a pathological new growth which tends to persist independently of the tissues in which it is found, and which serves no physiological purpose.

(*b*) *Signs of a malignant tumor* are: There is no capsule to the tumor, and so it invades the surrounding tissues, it spreads to distant organs, it produces a cachexia, it tends to recur after removal, and leads to inevitable death.

(*c*) *Sarcoma* is composed of mesoblastic (connective tissue) cells.

(*d*) *Carcinoma* is composed of epiblastic and hypoblastic (epithelial) cells.

10. *Edema* is a condition in which the fluid in the tissues is increased in quantity. *Five diseases which are a localized edema.* Ascites, hydrothorax, hydropericardium, hydrocephalus, and hydrocele.

GENERAL DIAGNOSIS.

I.

EXANTHEM.	INCUBATION PERIOD.	ERUPTION PERIOD.
Cerebro spinal meningitis.	Unknown.	2nd to 4th day.
Erysipelas.	Few hours to 3 or 4 days.	First day.
Measles.	10 to 12 days.	Fourth day.
Rotheln.	7 to 17 days.	Second day.
Scarlet fever.	1 to 21 days.	1st or 2nd day.
Typhoid fever.	5 to 30 days.	7th to 10th day.
Typhus fever.	4 to 12 days.	3nd to 7th day.
Varicella.	4 to 14 days.	First day.
Variola.	8 to 14 days.	About fourth day.

2. See French's "Practice of Medicine" (1910), pages 600 and 603; or Osler's "Practice of Medicine" (1909), pages 800 and 803.

3. Casts in the urine: *Hyaline casts* occur in the urine in all forms of nephritis, in congestion of the kidneys, in jaundice, and even in health. They are frequently the only casts present in chronic interstitial nephritis. *Waxy casts* occur especially in chronic parenchymatous nephritis. *Epithelial casts* occur especially in acute parenchymatous nephritis. *Granular casts* are especially common in chronic nephritis, but may occur in acute nephritis. *Fatty casts* occur chiefly in chronic parenchymatous nephritis. *Blood casts* occur in acute and chronic hemorrhagic nephritis. *Pus and bacterial casts* are occasionally met with in suppurative nephritis. (From Stevens' "Practice.")

4. *Otitis media* (inflammation of the middle ear, tympanum, or drum cavity) is divided into 4 clinical forms, viz.: acute catarrhal, chronic catarrhal, acute purulent, and chronic purulent otitis media.

Acute catarrhal otitis media is frequently caused by acute coryza and the infectious fevers. There is a painless obstructed sensation in one or both ears, impairment of hearing, and tinnitus. The inflammation causes closure of the eustachian tube.

Acute purulent otitis media.—Acute catarrhal otitis media, instead of undergoing resolution, may pass into acute purulent otitis media (especially in exanthemas) from the passage of pathogenic germs from the nasopharynx into the middle ear. The pain will become more intense, the hearing dull, tinnitus will become louder and more distressing, and fever usually sets in.

Chronic purulent otitis media is due to the permanent lodgment of staphylococci in the acutely inflamed middle ear. This unfortunate result is usually brought about by improper—*i. e.*, excessive—treatment of acute otitis media, generally by the patient, but sometimes, regrettably, by the physician.

The symptoms are a more or less copious and offensive discharge from the ear and a perforated membrana tympani. The perforation varies in size, and the ossicles may be more or less necrosed. Impairment of hearing, tinnitus, vertigo, attacks of so-called "gatherings in the ear," and earache are present.

Chronic catarrhal otitis media results from acute catarrhal otitis media that has failed to undergo resolution. Nasopharyngeal catarrh is usually associated with this condition. The onset is gradual, and is characterized by repeated attacks of the acute form, each one increasing in severity. As the symptoms of tinnitus and deafness increase, there may be attacks of ear vertigo of tympanic origin. These may be mistaken for neurasthenia, epilepsy, apoplexy, etc. Early in the case there are contraction of the tensor tympani, retraction of the chain of auditory ossicles, and consequent impaction of the stapes in the oval window.

Complications of middle ear disease are inflammation of the mastoid cells, caries and necrosis, phlebitis, meningitis, and brain abscess. (From Gould and Pyle's *Cyclopedia of Medicine and Surgery.*)

5. See Rose and Carless' "Surgery" (1908), page 539; or Da Costa's "Surgery" (1908), pages 521 and 601.

6. Syphilis, chancroid, and gonorrhea. And see Rose and Carless' "Surgery" (1908), pages 142, 147, 149, and 134; or Da Costa's "Surgery" (1908), pages 276, 1170, and 1156.

7. See French's "Practice of Medicine" (1910), pages 388 and 369; or Osler's "Practice of Medicine" (1909), pages 321, 329, and 335.

8. See French's "Practice of Medicine" (1910), pages 577, 579, and 581; or Osler's "Practice of Medicine" (1909), pages 785, 791, and 777.

9. See French's "Practice of Medicine" (1910), pages 101, 65, and 67; or Osler's "Practice of Medicine" (1909), pages 93, 59, and 61.

10. See French's "Practice of Medicine" (1910), pages 713 and 714; or Osler's "Practice of Medicine" (1909), page 652.

11. (1) *Talipes varus*, in which the inner edge of the foot is drawn up, the anterior two-thirds is twisted inwards, and the outer edge rests on the ground.

(2) *Talipes valgus*, in which the outer edge of the foot is drawn upwards, and the inner side of the foot and ankle rest on the ground. This condition is the reverse of *talipes varus.*

(3) *Talipes equinus*, in which the heel is raised and cannot be brought to the ground, and the patient walks on the toes and on the distal ends of the metatarsal bones.

(4) *Talipes calcaneus*, in which the toes are raised and the heel depressed, so that the patient walks on the latter. This condition is the reverse of *talipes equinus.*

12. See French's "Practice of Medicine" (1910), page 1067; or Osler's "Practice of Medicine" (1909), page 915.

BACTERIOLOGY.

1. *Scope of bacteriology.* The relation of bacteria to disease; the effects produced upon the animal body by the presence of bacteria and their toxins; the distribution of bacteria within the body; the reactions evoked by bacterial invasion; the channels by which bacteria leave the body; the presence of bacteria in water, soil, and air; the avenues by which bacteria enter the body; the subject of immunity. These are the main problems of bacteriology, in so far as the physician is concerned. *Classification.* Bacteria are primarily classified as: (1) Cocci, (2) bacilli, and (3) spirilla. *Methods of study* include: Sterilization, preparation of cultures and culture media, dilution, separation of species, preparation of pure cultures, animal inoculation, and microscopic methods.

2. The *structure* of bacteria is not settled. There is an outer cell membrane, a central fluid, and some protoplasm which constitutes the body of the cell. This last may be homogeneous or slightly granular. Vacuoles may be present. In some instances a capsule surrounds the bacterium. Bacteria multiply by fission. A bacterium about to divide seems to be larger than normal, and if it is a coccus it becomes more ovoid; changes occur first in the nucleus, and the bacterium just falls in two. It has been calculated that a single bacterium could, by fission, produce two in one hour. Fortunately, they seldom obtain food enough to keep up this process for any length of time. *Conditions of growth:* Most bacteria require proper temperature, generally at or near that of the body; oxygen is generally needed, those that cannot live without it being called aërobic, and those that can grow without it, anaerobic; nutriment of a proper kind, containing both organic and inorganic material; a slight degree of moisture; a medium of slightly alkaline reaction; and rest. Individual bacteria may require modifications of the above essentials.

3. *Temperature:* There are certain limits within which bacteria live and thrive, the temperature at which they grow best being called optimum temperature. Different bacteria have different requirements. Most of the pathogenic bacteria have their optimum temperature near that of the body. Steam under pressure will kill all bacteria and spores; very low temperature suspends their activity but does not necessarily kill them. *Light:* Bacteria thrive best in a subdued light; direct sunlight kills most of them; diffuse daylight inhibits their growth; electric light is germicidal. *Moisture:* This is necessary. *Oxygen:* See QUESTION 2. *Food supply:* See QUESTION 2. *Disinfectants and antiseptics:* These kill or restrain the growth of bacteria; the best germicides are heat, sulphur, formaldehyde, mercuric chloride, copper sulphate, carbolic acid, calcium hydroxide.

4. *Routes of infection:* Intravenous injection, by the alimentary tract, by the respiratory tract; through the skin, tonsils, mucous membrane of genital tract, and through wounds.

In *bactercmia*, bacteria are in the blood. In *toxemia*, the toxins alone (and not the bacteria) are in the blood.

By *mixed infection* is meant the infection of a part by the entrance of more than one kind of pathogenic microorganism at the same time. By *secondary infections* is meant that a part which is already infected is invaded by another kind of pathogenic microorganism.

5. A *spore* is a body formed inside some bacteria, to prolong their existence. Spores are capable of resisting deleterious influences such as high temperature, dessication, lack of nutrition, for a much longer time and to a greater degree than the non-sporulating bacterium.

6. *Infection may be transmitted* by: Air, food, water, flies, mosquitoes, or other insects, fingers or other contact, breath, fomites, urine, feces, sputum, nasal or other discharges.

7. Skin, mucous membranes, acidity of gastric juice, alkalinity of blood, bile, and pancreatic secretion, phagocytosis; and see French's "Practice of Medicine" (1910), page 55.

8. *Anaerobes* are bacteria that do not need oxygen. There are two kinds: (1) *Obligatory anaerobes*, which can only grow in the complete absence of oxygen; (2) *Facultative anaerobes*, which can thrive either in the presence or absence of oxygen. *Examples:* Bacillus of tetanus, bacillus of edema, bacillus of Welch.

9. The *Staphylococcus pyogenes aureus* is a small round cell which appears in clusters like a bunch of grapes; its diameter is about 0.8 to 1.0 micron: it is facultative anaërobic, has no flagella, is not motile, it stains readily with the anilin dyes, and is not decolorized by Gram's method; it forms an orange pigment on gelatin, potatoes, and other media; it also liquefies gelatin.

Staphylococcus pyogenes albus is about the same as the *Staphylococcus pyogenes aureus*, except that it does not form a pigment, and its colonies are of a white color.

Staphylococcus pyogenes citreus is about the same as the *aureus* and *albus*, except that its growth is of a lemon yellow color.

Staphylococci may be found in: Carbuncles, boils, abscesses, septicemia, pyemia, suppurative processes, osteomyelitis.

The *Stretacoccus pyogenes* is a micrococcus, of spherical shape, and arranged in chains of about thirty or forty cocci (in liquid media), but the chains are much shorter in solid media. Each coccus is about one-half to two mikrons in diameter. It is not motile, does not form spores, does not liquefy gelatin, and stains readily with the ordinary anilin dyes and by Gram's method.

Streptococcus erysipelatis appears in chains of varying

lengths or in tangled masses, the presence or absence of oxygen does not seem to be of much importance, it grows at room temperature, and has the cultural characteristics of the *Streptococcus pyogenes.*

Streptococci are found in: Erysipelas, abscesses, mixed and secondary infections, suppurative conditions, puerperal infections, endocarditis, pneumonia, diphtheria, septicemia, pyemia.

The *Gonococcus* is a diplococcus with a special predilection for the mucous membrane of the urethra; it is sometimes found on the conjunctiva. The appearance is that of two coffee beans; the gonococcus is found in the pus cells, stains with ordinary anilin dyes, but not by Gram's method. It is aerobic, and can be cultivated on human blood serum; it will not grow on gelatin, agar, bouillon, or potato. It was discovered by Neisser.

Gonococcus is found in gonorrhea.

10. *The three subdivisions of the colon typhoid bacillus group* are thus given by Jordan:

(1) *Bacillus coli;* the capsulated bacteria.

(2) The *Bacillus enteritidis* group, including *B. choleræ suis, B. icteroides, B. psittacosis,* and various "paracolon" and "paratyphoid" bacilli.

(3) *Bacillus typhosus* and *B. dysenteriæ; B. fecalis alkaligenes.*

Some of the main points of difference between the several subdivisions are shown in the following comparison:

B. COLI.	B. ENTERITIDIS.	B. TYPHOSUS.
Motility is not pronounced in most cultures; often only a few individuals in the field show independent movement; few flagella. Dextrose and lactose are fermented with gas production, some varieties fermenting saccharose also. Milk is curdled, usually within forty-eight hours, at 37°, with abundant acid production. Luxuriant growth on potato, usually with a brown tinge. Indol is produced by most varieties in large amount. Under most conditions not pathogenic for man or the lower animals. When injected intraperitoneally into rabbits and guinea-pigs a fatal result usually ensues, but considerable variation in virulence is shown by different strains.	Actively motile; 10 to 14 flagella. Dextrose is fermented with gas production, but no gas or acid is formed from lactose. Milk is never curdled; on prolonged cultivation under aërobic conditions the milk acquires a slight primary acidity, then becomes strongly alkaline, and finally the casein is dissolved. Indol is produced not at all or very scantily. Distinctly pathogenic for many of the lower animals and for man.	The typhoid bacillus is actively motile and possesses 10 to 14 flagella. B. dysenteriæ, otherwise closely related, is slightly motile or devoid of motility, according to some observers. Dextrose is fermented with production of acid, but gas is never produced; no acid is produced from lactose. Milk is never curdled, although a slight initial acidity develops, followed by a return to the original reaction; an alkaline reaction is produced in milk by some strains, but not to such an extent as in the preceding group. No indol is formed under ordinary conditions of cultivation. Pathogenic for man, less so for the lower animals.

—(Jordan's *Bacteriology.*)

11. *Spirilla* are bacteria having a spiral form. Examples: Spirillum of Asiatic cholera, of relapsing fever, treponema pallidum (of syphilis). *Protoza* are the lowest forms of animal organisms, consisting of a single cell (or colony of cells). Examples: Trypanosoma, plasmodium malariæ, and piroplasma.

12. *Sources of bacteria in milk:* Udder of the cow, hands or clothes of the milker, vessels, water used to wash vessels or cow's udder or to adulterate the milk, the dust of the cowbarn, and from contamination during transit from the cow to the consumer. *Freshly drawn milk is not sterile.*

What is the largest number of bacteria permissible in milk offered for consumption cannot be ascertained. "The requirements of the New York Milk Commission specify that certified milk shall contain not more than 30,000 bacteria per cubic centimeter, and those of the Philadelphia Milk Commission that it shall not have more than 10,000. Boston puts the limit at 500,000, and Milwaukee at 250,000."—(Jordan.)

HYGIENE.

1. *Hygiene* is the science and art of the preservation and promotion of human health.

Contagion is the process by which a specific disease is communicated from one person to another.

Infection is a disease-producing agent, or a disease produced by a microorganism.

For *Epidemic, Sporadic, Endemic, Pandemic, Fomites, Mediate, Immediate,* see French's "Practice of Medicine" (1910), pages 5 and 6.

Atmospheric means pertaining to the atmosphere.

Telluric means derived from the earth.

2. See French's "Practice of Medicine" (1910), page 324; or Osler's "Practice of Medicine" (1909), page 138.

3. *Potable water* should be colorless, odorless, cool, limpid, soft; it should have an agreeable taste, neither salty nor sweet nor flat; it should dissolve soap readily without formation of a curdy precipitate; it should contain not more than about twenty-five to thirty grains of solids per gallon, and should not be polluted with sewage.

The sources and varieties of water have been classified thus:

Wholesome.	1. Spring water	very palatable.
	2. Deep-well water	moderately palatable.
	3. Upland surface water	moderately palatable.
Suspicious.	4. Stored rain water	moderately palatable.
	5. Surface water from cultivated land	palatable.
Dangerous.	6. River water, to which sewage gains access	palatable.
	7. Shallow-well water	palatable.

Polluted water may cause: Typhoid, cholera, dysentery. Water should be boiled and filtered (preferably by the Pasteur-Chamberland or some other porcelain filter).

4. The International Sanitary Convention of Paris, in 1903 issued the following provisions: "In the case of *plague, infected* ships shall undergo the following measures: (1) Medical inspection; (2) the sick shall immediately be disembarked and isolated; (3) the other persons must also be disembarked if possible, and either be kept under observation during a period which shall not exceed five days and which may or may not be followed by surveillance of not more than five days' duration, or merely be subjected to surveillance during a period which shall not exceed ten days. The period shall date from the arrival of the ship. It rests with the sanitary authority of the port, after taking into consideration the date of the last case, the condition of the ship, and the local possibilities, to take that one of these measures which seems to them preferable; (4) such soiled linen, wearing apparel, and articles belonging to the crew and passengers as are, in the opinion of the sanitary authority, infected shall be disinfected; (5) the parts of the ship that have been occupied by persons ill with plague, or that, in the opinion of the sanitary authority are infected, must be disinfected; (6) the rats on board must be destroyed, either before or after discharge of cargo, as quickly as possible and, in any case, within a maximum time of forty-eight hours, and so as to avoid damage to merchandise and to the ship's plating and engines. In the case of ships in ballast, this process must be carried out as soon as possible before taking cargo.

"In the case of *plague, suspected* ships shall undergo the measures specified in (1), (4), and (5) above. In addition, the crew and passengers may be subjected to surveillance, the duration of which, dating from the arrival of the ship, shall not exceed five days. The crew may, during the same period, be prevented from leaving the ship except on duty. Destruction of rats on board is recommended. This process shall be carried out, either before or after discharge of cargo, as quickly as possible and, in any case, within a maximum time of forty-eight hours, and so as to avoid damage to merchandise and to the ship's plating and engines. In the case of ships in ballast this process, if there be occasion for it, shall be carried out as soon as possible and, in any case, before taking cargo."—(Simpson's *Treatise on Plague.*)

In addition, see French's "Practice of Medicine" (1910), pages 287 and 295.

5. MILK. *Composition:* 87 per cent water and 13 per cent solids (proteids, fat, and sugar, each about 4 per cent, and mineral matter less than 1 per cent). *Source:* Ordinarily, the cow. *Preservation:* By low temperature, boiling, sterilization, Pasteurization.

Milk may be sophisticated or adulterated by: (1) Skimming; (2) the addition of water; (3) the addition of coloring matter, such as caramel, annatto, or methyl orange; (4) the addition of preservatives, as boric acid, formaldehyde, salicylic acid, or salicylates; (5) the addition of arrowroot, flower, sugar, glycerine, chalk, or sodium carbonate.

For antiscorbutic remedies for the bottle-fed baby, see French's "Practice of Medicine" (1910), page 547; or Osler's "Practice of Medicine" (1909), page 754.

6. "To trace an epidemic to its source is not so much a study for the doctor as for the statistician, the detective, the bacteriologist, the chemist, and the engineer." Find out who have the disease, where they live, and when and where they were taken sick; investigate the use and source of water, milk, and food among the sick. If food or milk can be traced to one dealer, or food to the same source, much is accomplished; inspection of farms and dairies may be necessary. Oysters and "carriers" must be remembered.—(From Whipple's *Typhoid Fever.*) And see French's "Practice of Medicine" (1910), page 107; or Osler's "Practice of Medicine" (1909), page 96.

7. The DETENTION PERIOD, after exposure to *smallpox*, is about 16 days; *scarlet fever*, about 10 days; *diphtheria*, about 12 days; *measles*, about 16 days; *cholera*, about 7 days; *bubonic plague*, about 8 days; *typhoid*, about 21 days; *yellow fever*, about 7 days.

9. See French's "Practice of Medicine" (1910), page 396; or Osler's "Practice of Medicine" (1909), page 351.

10. For *disinfection of rooms*, use formaldehyde gas; *clothing*, use solution of phenol (5 per cent.) for an hour, then boil for an hour; *person*, wash in soap and water, and then with cresol or carbolic acid solution; *bedding*, use steam or formalin; *excreta*, etc., should be passed into vessels containing dilute solution of formalin, of greater quantity than the expected excretion.

11. Malaria is *caused* by the plasmodium malariæ, but *carried* by the anopheles mosquito. The cause of yellow fever is not yet determined, but it is *carried* by the stegomyia mosquito.

Prophylaxis of malarial fever. Individuals should use mosquito netting round their beds and wire gauze in doors and windows so as to keep out the mosquitos as much as possible. During residence in malarial districts quinin should be taken every morning before breakfast. All pools, stagnant water, etc., where *anopheles* may breed, should be removed. All mosquitos, larvæ, etc., should be destroyed as far as possible. By staying indoors during dusk and darkness, opportunities for infection may be avoided. Occasional fumigation with formaldehyde or sulphur is also efficacious.

To prevent yellow fever in the tropics: All cases of the disease should be isolated; houses should be protected by mosquito netting; mosquitos should be killed; swamps should be drained.

12. *Drinking water* for a school should be the best obtainable; should be filtered through a properly adjusted and frequently cleaned filter, and individual cups should be supplied. *Heat* should be from a central plant; heated steam radiators or coils should be in a separate air chamber, whence the warmed air is forced by proper motors and fans into the ducts leading into every room where they end in inlets in appropriate locations. *Light:* "The window area of school houses should be not less than one-fourth of the floor space; the top of windows should not be more than six inches from the ceilings; the windows should be square on top and reach to about four feet from the floor; the piers between windows should be as narrow as possible and bevel-edged, the panes made in large dimensions without intervening bars. The window glass should be ribbed, or prism glass. School rooms should be lighted from above, wherever possible, and from the left on all floors where light cannot be gotten from above. For artificial illumination electric lights are the best." *Ventilation:* This should be mechanical, with a combined vacuum and plenum system, with the supply of air carefully regulated as to temperature, quantity, humidity and purity. *Sewerage:* "There should be ample provision for wash rooms, basins, shower baths, urinals, water closets, all situated conveniently in well lighted, heated and ventilated apartments; the fixtures made of enameled iron or porcelain, the floors, walls and ceilings of such apartments constructed of stone, tile or pressed glass. Water closets should be provided with automatic flush apparatus." (From Price's *Hygiene and Public*

OBSTETRICS.

1. *Bones:* Ilium, ischium, pubis, sacrum, and coccyx. *Diameters:*

	Antero-posterior.	Oblique.	Transverse.
Brim	4 inches	4½ inches	5 inches
Mid-plane	4½ "	4½ "	4½ "
Outlet	5 "	4½ "	4 "

2. DIAGNOSTIC SIGNS OF PREGNANCY: See Williams' "Obstetrics" (1909), page 180; or Hirst's "Obstetrics" (1909), page 191.

PUERPERAL ECLAMPSIA. *Etiology:* Uremia, albuminuria, imperfect elimination of carbon dioxide by the lungs, medicinal poisons, septic infection; predisposing causes are renal disease and imperfect elimination by the skin, bowels, and kidneys. *Symptoms:* Headache, nausea, and vomiting, epigastric pain, vertigo, ringing in the ears, ashes of light or darkness, double vision, blindness, deafness, mental disturbance, defective memory, somnolence; symptoms easily explained by the circulation of toxic blood through the nerve centers. These may be preceded by lassitude, and accompanied by constipation, or by diarrhea. Headache is perhaps the most significant and common warning symptom. In bad cases the urine is reduced in quantity (almost suppressed), very dark in color, its albumin greatly increased, so that it becomes solid on boiling. Next comes the final catastrophe of convulsions. The convulsive fit begins with twitching of the facial muscles, rolling and fixation of the eyeballs, puckering of the lips, fixation of the jaws, protrusion of the tongue, etc., soon followed by violent spasms of the muscles of the trunk and limbs, including those of respiration; hence lividity of the face and stertorous breathing, biting of the tongue, opisthotonus, etc. The fit lasts fifteen or twenty seconds, ending in partial or complete coma, possibly death; or consciousness may return, to be followed by other convulsions.—(King.)

PHLEGMASIA ALBA DOLENS is a form of manifestation of puerperal sepsis in which there is a thrombosis of the iliac or femoral vein. Sometimes it occurs after a uterine phlebitis, in which clots are carried from the uterine sinuses to the hypogastric veins, where they cause obstruction to the blood flow in the crural veins. The trouble may also begin as a crural phlebitis. It is thus due either to cellulitis or to thrombosis. It usually appears about the third or fourth week of the puerperium.

PRURITUS VULVÆ may be *caused by:* Parasites; diseases of the vulva, as inflammation, edema, vegetations, congestion, irritating discharges, lack of cleanliness, diabetic urine; it may also be of nervous origin, or idiopathic.

MORNING SICKNESS may be *caused by:* (1) Reflex disturbance, due to rapid growth and excessive distention of the uterus; (2) disease or displacement of uterus, tubes, and ovaries; (3) disease of pelvis or gastrointestinal tract; (4) excessive sexual intercourse; (5) renal disease or disturbance.

3. See Williams' "Obstetrics" (1909), pages 172 and 175; or Hirst's "Obstetrics" (1909), pages 185 and 186.

4. In *tubal pregnancy* there will be signs of early pregnancy, hypogastric or inguinal pains, probable history of a previous sterility, probable expulsion of decidual membrane or shreds, softening of the cervix, enlargement of the uterus, presence of a distended tube, contractions of the wall of the gestation sac; if rupture occurs, there will be sudden, excruciating pains over the lower abdomen and on the affected side, shock, collapse, and symptoms of internal hemorrhage. In *acute salpingitis* the tube is inflamed, there is generally either an inflamed uterus or infection (gonorrheal or puerperal), backache, pain in lower abdomen, history of menstrual inequality but no signs of early pregnancy, leucorrhea, tube is enlarged and tender.

For *placenta prævia* and *fibroid tumor* see Williams' "Obstetrics" (1909), page 814; or Hirst's "Obstetrics" (1909), page 577; also in *uterine fibroid:* Menstruation is irregular and sometimes very profuse; absence of the signs of pregnancy; the tumor is nodular, firm, irregular in outline, and while generally placed somewhat centrally is not in the median line, and is not symmetrical; the rate of growth is irregular, being, as a rule, slow, and sometimes extending over years.

5. See Williams' "Obstetrics" (1909), pages 617 and 373; or Hirst's "Obstetrics" (1909), pages 276 and 797.

6. See Williams' "Obstetrics" (1909), pages 225 to 230; or Hirst's "Obstetrics" (1909), pages 317 to 324.

7. See Williams' "Obstetrics" (1909), pages 397 and 400; or Hirst's "Obstetrics" (1909), pages 809 and 811.

8. See Williams' "Obstetrics" (1909), pages 285 and 422; or Hirst's "Obstetrics" (1909), pages 419, 425, and 824.

9. See Williams' "Obstetrics" (1909), page 846; or Hirst's "Obstetrics" (1909), page 939.

10. See Williams' "Obstetrics" (1909), page 875; or Hirst's "Obstetrics" (1909), page 728.

11. *Ophthalmia neonatorum* is an infectious, purulent inflammation of the conjunctiva in the new-born. It is due to the gonococcus or some other pyogenic germ; and is produced by contact of the eye with the vaginal secretion of the mother during labor, or infected fingers, or instruments, etc. For *symptoms* see Hirst's "Obstetrics" (1909), page 948; the *danger* is loss of sight.

12. See Williams' "Obstetrics" (1909), page 303, or Hirst's "Obstetrics" (1909), pages 326 and 374.

GYNECOLOGY.

1. See Williams' "Obstetrics" (1909), page 904, or Hirst's "Obstetrics" (1909), page 645.

2. Tears of the perineum destroy the integrity of the pelvic floor and result eventually in rectocele, cystocele, hemorrhage, and displacements of the pelvic organs. If the tear involves the sphincter ani, incontinence also results.

3.

PELVIC PERITONITIS.	PELVIC CELLULITIS.
Uterus usually surrounded and fixed by an infiltrate.	Tumor usually at side of uterus.
Blocking up of the vaginal fornix all around uterus.	Bulging of one or both lateral fornices, seldom surround uterus.
Mass rather high in pelvis.	Mass lower in pelvis and easily palpated.
Pain severe and paroxysmal in acute stage.	Pain less severe and more continuous.
Cervix usually fixed in median line with corpus in anteversion or anteflexion.	Uterus usually displaced laterally.
Frequently results in general peritonitis.	Not frequently so complicated.
Anxious facial expression.	Facial expression not characteristic.
Both legs flexed on abdomen.	One leg flexed, seldom both.
Nausea and vomiting frequent.	Less frequent.
Exudate may extend to upper zones of pelvis.	More generally confined to lower zones.
Pulse rapid and weak.	Not so rapid; not weak.
Tongue dry.	Tongue may be moist.

—(Dudley's *Gynecology.*)

4.

FIBROID TUMOR.	OVARIAN CYST.
Slow growth.	Usually more rapid growth.
Facial expression unchanged. Face may be full and flushed; later pale from hemorrhage.	Facies ovariana.
General health usually unimpaired except from loss of blood, if submucous or mural; may be painful.	General health early impaired from emaciation. Not painful.
Abdomen usually very asymmetrical from irregular shape of tumor.	Abdomen more symmetrical, especially when tumor is large.
Abdominal veins not usually enlarged.	Usually enlarged, especially in large polycysts.
Action of kidneys normal.	Kidneys less active.
Usual menorrhagia.	Menstruation unchanged or diminished.
Elasticity, not fluctuation. No percussion wave.	Fluctuation marked. Percussion wave marked.
Surface firm and usually lobulated.	Surface yielding; in monocysts, regular; in polycysts, irregular.
Vaginal touch and conjoined examination show tumor dense and firm, and, unless pedunculated, continuous with uterus. Uterus large and heavy.	Uterus normal, except displacement from pressure. Tumor compressible, fluctuating, detached from uterus.
Uterine cavity much elongated.	Not materially elongated. (This is a most important diagnostic point.)
Uterus moves with tumor.	Does not move with tumor.

—(Dudley's *Gynecology.*)

5. The normal position of the uterus is one of slight anteversion, with its long axis at right angles to the long axis of the vagina. Abnormal positions are: Retroversion, retroflexion, anteversion, anteflexion, lateral version, lateral flexion, descent or prolapse, ascent, and mallocation (to front, back, or one side).

6. See Williams' "Obstetrics" (1909), pages 639 and 647; or Hirst's "Obstetrics" (1909), pages 295 and 303.

7. *Leucorrhea* is a discharge (not bloody), generally whitish and mucopurulent, from the female genital tract. It is a symptom, and may be due to any morbid processes that lead to hypersecretion of the mucous glands, of vulva, vagina, cervix, uterus, or tubes. The glands of Bartholin may also be involved. The gonococcus *may* be present; the colon bacillus, streptococcus, staphylococci, and other organisms are also commonly present.

8. *Cancer of cervix:* Laceration and erosion are predisposing factors. It occurs most frequently between the ages of 35 and 50. The symptoms are hemorrhage, pain, and discharge. The diagnosis is made on the physical and microscopical examination. The cervix is hard and nodular, and the mucous membrane seems immovably fixed to the underlying tissue. These nodules break down, the entire cervix becomes ulcerated, or large cauliflower-like masses may fill the upper part of the vagina. The diseased tissue is friable and bleeds upon touch. The causes of death are exhaustion, sepsis, and hemorrhage.

9. *Urethral caruncle* is a small red fleshy growth generally situated on the posterior part of the meatus of the urethra. There are local pain and tenderness, which may be excessive; a burning sensation is experienced on urination; it may bleed.

10. *Bartholinitis* is inflammation of the glands of Bartholin; the *germ* is generally the gonococcus. *Symptoms:* A tumor with or without much inflammation over the site of the vulvo-vaginal gland; pain on walking. *Prognosis* is good.

11. In *appendicitis* the pain is of sudden onset and is localized in the right iliac fossa; there is abdominal rigidity, chiefly of the right rectus muscle, and tenderness at McBurney's point; there are usually fever, nausea, vomiting, and constipation.

In *inflammation of the right ovary* the pain is not localized, but may be bilateral, and spreads to the vagina and rectum; there is no tenderness at McBurney's point; it is usually worse just before the menstrual period, which sometimes affords relief; on vaginal examination the ovary is found to be tender.

12. *Climacterio* is the menopause, or period when menstruation ceases. "It is characterized by the following senile changes in all the reproductive organs: *Ovary:* Atrophy, induration, and shrinkage to rudimentary size; disappearance of Graafian follicles; cessation of function. *Fallopian tubes:* Shortening and narrowing, often complete obliteration of lumen; destruction of epithelial elements. *Uterus:* Atrophy of entire organ to rudimentary size, may be reduced to a hard wedge-shaped body one-fourth size of mature organ; muscular and glandular elements become rudimentary; canal may close at internal os or external os, or become obliterated throughout; secretions may be locked up by obliteration of the cervical canal, producing pyometra or hydrometra; vaginal portion may disappear, making the upper part of the vagina continuous with the uterine canal. *Vagina:* Shortening, narrowing, and loss of elasticity; loss of pavement epithelium, and substitution of a hard surface containing more or less cicatricial tissue; contraction of introitus vaginæ."—(Dudley's *Gynecology.*)

Bacteriological and Clinical Studies of Puerperal Infections.—G. L. Basso has made a study of the bacteriology of the lochia from vagina and uterus in 100 normal pregnant women at different months of pregnancy, of 150 normal puerperal women, and of 82 cases of puerperal infection of varying degrees. From his studies he gives the following conclusions: In 25 per cent. of healthy pregnant women we find streptococci present in the lochia; even the hemolytic form may be present in 4 per cent. without any harm occurring from their presence. In women in labor, even when febrile, the blood presents no germs. In normal puerperal women in the uterine lochia the streptococcus is present in 13 per cent.; in saprophytic conditions, in the vaginal lochia they are present in 38 per cent. In 64 per cent. of puerperal infections of varying degrees of severity streptococci were found in the lochia, and in 17 cases they were hemolytic. The presence of these germs is not an indication of virulence of the disease, nor a reason for giving a bad prognosis. Their presence is to be considered of serious import only when the clinical symptoms are at the same time severe and fever and pulse are unfavorable.—*Folia Gynæcologica.*

Books Received.

The MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading, but it must be with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

THE MEDICAL SIDE OF THE ARMY MANEUVERS IN TEXAS.

By N. S. JARVIS, M.D.,

NEW YORK.

MAJOR MEDICAL CORPS, N. G. N. Y., CAPT., U. S. ARMY (RETIRED).

SIXTY-FIVE years ago an American army mobilized at Corpus Christi, in Texas, three days' march from San Antonio, destined to add glory to our national history and increase our territory to a vast empire. Primitive, indeed, were the preparations of that period compared with modern conditions, conditions which, however, add to the perils which face the soldier of this period. Indeed, the lovers of international peace see in these new dangers the eventual solution of the problem they seek to solve. Nor can it be said that shot and shell are the worst elements of modern war; in a thickly settled country "the pestilence that walketh by night" is a foe not less to be dreaded than the weapon of the enemy. It seems needless again to emphasize the horrors of our camps in the late war with Spain—now a hackneyed story—but it may be merely added in passing that "it is an ill wind that blows no good;" and that brief disturbance, as we know, was productive of a development and knowledge of disease which might not have accrued in a century of peace. Our revolutionary conception of the spread of typhoid fever, yellow fever, and malarial infections have added vastly to the safety and happiness of the human race, and had the English accepted the findings of our own medical officers the story of typhoid fever in the South African campaign might have been an unprinted chapter.*

Believing that many may be interested to hear what is being done by the Army Medical Corps in Texas, the writer will briefly describe the preparations which that department of our army is making for a possible campaign. Every facility and courtesy have been extended by the alert and practical division surgeon, Colonel H. B. Birmingham, United States Army, and his efficient assistants. Every question has been patiently answered, and the utmost pains taken to make clear the methods adopted to avert disaster to the army from disease and to care for the wounded in campaign. Some adverse criticisms of this department have appeared in lay papers, based, as is usually the case, upon gross ignorance of the situation and a too great willingness to criticise without investigation. It is hoped, however, that the members of our profession, at least, will suspend judgment long enough to digest the facts that are here submitted.

Description of the Army.—Although the field army at San Antonio would have a tactical strength of approximately 19,000 men, on a war footing, the actual strength of the division at the present writing is about 12,000 men. This is due to the fact that all the units ordered to mobilize were on a peace footing, which is about 35 per cent. short of a war complement, and, in fact, most of these organizations were not up to the full strength of the peace footing. The division consists at present of a cavalry brigade of three regiments, an artillery brigade of three regiments of field artillery, three infantry brigades, two signal corps companies, and a batallion of engineers. Some slight changes have been made in these organizations for experimental purposes, but this would not interest your readers.

We now come to that feature of the army which most interests our profession, and I may add, in parenthesis, that this is the first time that a complete tactical sanitary organization has been brought together in accordance with the new field service regulations.

Four complete ambulance companies and four field hospitals make up the complement. The personnel of the hospital corps lacks 150 men, and the medical corps, which should aggregate 101 officers, now numbers 78, but the vacancies in men and officers are being rapidly filled. There is also a shortage of about 150 mules, to supply all the demands of the Medical Department in campaign, although the number on hand is quite sufficient for present conditions. Men and animals are being rapidly forwarded to make up deficiencies, so that in a few days there will be not even a theoretical defect in the tactical makeup.

Description of the Camp.—The division is mobilized on a vast plain to the north and east of Fort Sam Houston, partly within the limits of the fort, and partly on leased ground; the soil is a black loam containing a large percentage of lime, hard as flint when dry, and sticky and tarry when soaked with rain. A few feet from the surface one strikes an almost solid bed of limestone, so that the soil is not an ideal one from a sanitary standpoint. Owing to the flatness of the ground, drainage is difficult to maintain, and surface water must disappear by evaporation or be carried off by surface drains where the contour of the camp permits. Drinking water is abundant and palatable, containing, as does most of the water of this region, a considerable percentage of lime salts. This hardness in some excites slight enteric disturbance which, as a rule, quickly subsides. The water has been piped to the camp from the city supply, so that this important demand of a good camp is abundantly met.

Unfortunately, however, one serious danger faces this camp and should epidemic disease appear, its source will be self-evident. Adjoining the south

*See editorial in the *Army and Navy Journal*, April 22, 1911.

*These figures do not include the separate brigade of coast artillery at Galveston, which is not touched upon in this review.

end of the grounds is a collection of squalid frame structures, liquor saloons, and other places of evil nature, some quite recent in construction, but most of them the result of the abolition of the post canteen. These "hog ranches," so aptly termed by the soldier, would be a fitting abode for the animal whose name they bear, in search of congenial surroundings. Individually and in company with the division surgeon, the writer has inspected the vicinity and evidences of human pollution and other filth were quite sufficient to indicate danger. I am told a complaint has been filed with the city health authorities, but practically nothing has been done to remove the peril. A city without a public hospital can hardly be expected to provide for the isolation and prevention of epidemic diseases, and any community which will permit the condition which I have witnessed adjoining this camp, would hardly be considered a safe neighbor for a large force of military. It is needless to add that the usual venereal peril exists here as in all towns, but the percentage of infected is not larger than at the home stations; but it is quite large enough to keep up our unenviable record in this respect.

Sanitation of the Camp.—As this was supposed to be a temporary camp, the latrine privy system is in use, and up to the present date it has been in every way satisfactory. The writer has always contended that the incinerator, so much employed at some of the permanent camps, in addition to the original cost and expense of operation, has prompted an unreasonable fear of the latrine privy and neglect of its proper construction and care. There is no doubt, however, that the latrine, improperly dug and not scrupulously cared for, would greatly imperil a camp, but when rigidly sterilized it may be safely used, and moreover obviate the odor of the incinerator, which is another serious objection to that apparatus. It is true that the incinerator is claimed by its friends and makers to be a portable machine, but its weight is not inconsiderable, and if fuel is not available that must also be carried. In a camp supposed to be a temporary point of organization, the installation of these impedimenta would be absurd. The latrines at this camp conform to the regulation standard as to depth, length, and breadth, and when the contents approach within two feet of the surface the trench is thoroughly sterilized with lime, burned out with straw and petroleum, marked for identification, and a new ditch is dug in its neighborhood. Each pit is daily sterilized by burning with straw and petroleum and the structure, containing the seats, is inverted each day and its interior thoroughly washed with liquid chloride of lime; each seat is provided with covers so arranged as to close over the opening after use. At the angle of the box frame a urine trough is inserted, while at the end of each company street metal barrels are provided for use at night, evacuated, and thoroughly sterilized in the morning.

All solid and liquid refuse from the kitchens is burned at the kitchen crematory, which has proven so effective at Pine Plains and other camps. This is constructed by digging an oblong ditch lower at one end than at the other, and filling within two feet of the surface with broken stone. The heated stone, as the refuse comes in contact with it, is a means for constant sterilization of the liquid, and incineration of the solid refuse. Manure from the stables and picket lines is carried off to a distant dump and there burned under the supervision of sanitary officers.

An excellent procedure is here carried out to further obviate the fly nuisance, and consists in the frequent burning of the picket line with straw and petroleum; for this purpose crude petroleum is furnished to the extent of 20 gallons a day to each picket line. This procedure will kill the larvæ which might be deposited in the soil, and which, in spite of sweeping and raking, often complete the cycle of development.

The medical officer of each unit is held responsible for the proper scrutiny and supervision of his camp and is required to report at once to his immediate commander the existence of sanitary defects. The sanitary control of the entire camp is completely within the grasp of the medical officer and sanitary personnel, as is also all transportation and equipment which may be necessary for this purpose. The sanitation of a large camp, however, can be accomplished only with the consent and cooperation of the line officer, and there is every evidence that the medical corps at San Antonio is receiving every practical and moral aid from the commanding general to the junior subaltern.

Prophylaxis.—As soon as this army mobilized, the Secretary of War, upon the recommendation of the Surgeon General of the army, decided that antityphoid inoculation was a military necessity, and ordered its immediate adoption. From the commanding general down, every officer and man has been vaccinated, and as the recruits arrive they are also protected. In a few instances, where there is evidence that men are recent convalescents from typhoid, this measure is dispensed with upon the advice of the medical officer.

The usual precautions against variola are also rigidly followed, and where there is the least doubt of a man's immunity he is at once revaccinated. All recruits are quartered in barracks at the Fort and kept under the careful supervision of medical officers, for it is from this class that infection of a command usually has its origin. The presence of measles and mumps among the recruits has justified the precaution. Antityphoid inoculation, as here practice, consists in the injection of 0.5 c.c. of dead bacteria (500,000,000) at the insertion of the deltoid, to be followed, at the end of ten days, by a second injection. The skin is sterilized previous to injection by painting with tincture of iodine. No untoward results beyond some slight discomfort have followed this procedure.

The most important item to mention, however, in connection with this camp, and the precautions which have been so carefully maintained, is the fact that after one month no case of enteric fever has appeared. When the command arrived at San Antonio the usual fly screening at the kitchens was not constructed, but as there seems to be no immediate prospects of putting the army in motion, kitchens and storerooms are being guarded against this household pest. At the present writing, few flies are appearing in the camp, and, indeed, unless they come in swarms from the town itself, it is difficult to imagine how they can flourish on this ground. No cases of malarial infection have appeared, although each man is provided with mosquito netting should necessity demand protection.

Each regimental infirmary is provided with an abundant supply of the Slee package, which consists of a wooden cylinder with an ointment of calomel at one end and a solution of argyrol (20 per cent.) for injection at the other end. Any soldier who desires to receive the benefits of this means of

prevention may do so on application to the hospital sergeant in charge of the infirmary. These "lady pencils," as they are jocularly termed by the enlisted men, it is hoped will avert a considerable loss of time to the government, and suffering to the soldier from venereal infection.

The division has attached to it an expert bacteriologist, who examines the blood of any man who shows a rise in temperature lasting 48 hours. He is also supposed to be the official chemist for the division and is prepared to examine drinking water, or do any other chemical work which might be demanded. For practical purposes a complete chemical and bacteriological field set has been arranged by Major Russell, of the Medical Corps, and a folding Leitz microscope, in use in the German army, is a part of the equipment.

Care of the Sick.—Up to the present one field hospital has answered the requirements of the command, and a few serious cases, such as pneumonia, have been treated in the base hospital at Fort Sam Houston. But one death has occurred, the result of pneumonia complicating measles.

No case of alcholism has been placed on record, a remarkable showing for such a large body of young men with the temptations which surround them. This does not mean that there is not more or less drinking, but it does indicate that few have been disabled by intemperance.

Sanitary Instruction.—The division surgeon is provided with an executive officer, Major Elbert Persons, and a sanitary inspector, Major Paul Straub, of the general staff, both men of wide experience and sound judgment. Major Straub has instituted the instruction of medical officers in the solution of field problems, involving operations of the sanitary corps in battle—sanitary tactics—so called. This consists of the establishment of ambulance and dressing station, the location and demarkation of the line of evacuation, and the eventual disposal of the wounded into the field hospitals for their removal to the base hospital; these experiments also contemplate the addition of such material as may be needed in a lengthy campaign or the abandonment of superfluous impedimenta, also the careful scrutiny of transportation facilities and the personnel of the sanitary corps, with a view to their greatest efficiency in campaign. The great military reservation at Leon Springs is used as a maneuver field, and so far the units involved have been relays of infantry brigades. Sanitary problems have been instituted with troops in both defensive and offensive positions.

When a field problem is contemplated, medical officers of the organization are provided with maps of the field indicating the location of the field hospitals. Upon these maps they will indicate the location of the ambulance station and dressing stations adopted for the use of their command. These maps are placed in the hands of the chief surgeon in the field so that he is always in touch with the various stations provided for the care of the wounded. These problems will vary somewhat, depending upon whether the evacuation of the wounded be by rail, water, or wagon transportation. Before and after these maneuvers the tactical problems are discussed among the medical officers and due consideration must be given as to the possible character of the assistance to be given at each station, and the material which is at hand for the purpose. The discussion might also involve the anticipated percentage of wounded at each station, which might vary according to the strategic position.

In most of these problems a divisional casualty of 10 per cent. is assumed. This would mean that the entire division in battle would sustain a loss of 1,600 wounded and 400 killed. The problems further involve the preparation of records, the use of identification tags, etc.; the card system, which is in general use in the medical corps, begins on the battlefield, and the card prepared by the surgeon in charge of the field hospital is forwarded to the office of the surgeon general for filing. In the study of all these problems, medical officers assigned for instruction take an active part, and in my conversation with them they expressed much enthusiasm at the unique opportunity which is here offered for the study of field problems.

Camp sanitation has been so thoroughly drummed into the ears of the militia medical officer that he is well equipped in this respect, but in the study of field problems here referred to he has had few opportunities. Every facility has been extended to officers from the various States to see everything and derive every advantage which can be given them at this camp. The division surgeon has given particular instructions to his subordinates to show every courtesy to these officers, and he has emphasized the fact that after all, medical officers, whether of the army or the organized militia, are doctors and stand on the same professional platform. This constitutes a bond of union which does not exist among line officers from the States and those of the regular army, and there is no doubt but that in some instances the entente cordiale has not been so marked.

There are many things which might be further elucidated in connection with this mobilization, but sufficient has been said to show the revolutionary changes which have taken place in the medical department of the army, and that no pains or expense have been spared to protect the army from disease, or care for it in battle.

MANHATTAN CLUB.

DREAMS AND THEIR ANALYSIS IN REFERENCE TO PSYCHOTHERAPY.*

BY H. W. FRINK, M.D.,

NEW YORK,

ASSISTANT ATTENDING PHYSICIAN TO CORNELL DISPENSARY, DEPARTMENT OF NERVOUS DISEASES.

THE problem of the dream has been perhaps one of the most baffling with which psychologists have had to deal. Though considerable attention has been paid to it by scientific writers, little approach to a solution had ever been made, until Freud came forward with his epoch-making work, "Die Traumdeutung."[1] The studies of this observer have already practically revolutionized our ideas of psychoneuroses, but perhaps none of his labors is worthy of more admiration, or has contributed more to our knowledge of the mind, than his work on the psychology of dreams. In the light of his interpretation the dream is no longer a senseless phantasy, without meaning, reason, or value; but it appears as the product of quite logical mental action, an expression of the individual's inmost thoughts, and it forms a path by which one may enter and explore psychic regions heretofore almost inaccessible.

The day-dream or reverie, a creation with which we are all familiar, obviously plays a great part in

*Read in abstract before the Psychiatric Society of the Manhattan State Hospital, January 23, 1911.

the life of each one of us, and contributes largely to human happiness. The day dream and the night dream, though superficially very dissimilar, are nevertheless analogous. Both night dreams and day dreams may be said to correspond to the fulfilment of a wish. We desire or wish for something and in the dream we see our wishes realized; we, in fancy, possess the things we desire, and that for which we hope actually comes to pass. But in the night dream the wish or latent thought rarely appears clearly but is represented in some symbolic manner, and in a condensed or distorted form. The wishes that are fulfilled in day dreams generally relate to things we most desire and for which we are consciously striving, but night dreams deal with wishes and cravings which are outside the full light of our consciousness and of which we are more or less unaware. They are often wishes which are incompatible with the dreamer's idea of his own personality; they are wishes which he will not admit even to himself. Such wishes were conscious at some time but because they were undesirable, for moral reasons, etc., have been put out of mind and forgotten. But though they are out of mind they are by no means inert; they continue to seek fulfillment and, while the individual is asleep, they find it.

This exclusion from consciousness,* this putting out of mind of the undesirable, is accomplished by a psychic mechanism which Freud calls "repression." In the young infant "there is absolutely no such brain power existant as mental inhibition; no desire or tendency is stopped by a mental act," but "at a year old the rudiments of the great faculty of self-control are clearly apparent in most children. They will resist the desire to seize the gas flame, they will not upset the milk jug, they will obey orders to sit still when they want to run about."[2] At this age, however, impulses are resisted only because of the dread of immediate and painful consequences, and not on account of any moral scruples. It is only when the child reaches the age of five to eight or so that ethical or esthetic considerations have sufficient weight to deter him from gratifying any desire he may happen to have. At this age he has begun to possess definite ideas of his own character, he is conscious of himself as a personality, and he is anxious to respect himself. He learns that the gratification of some impulses he may possess would be wrong, shameful, or disgusting; and as he does not wish to look upon himself as an individual possessed of wrong, shameful, or disgusting desires he not only resists the impulse to gratify them, but he endeavors to suppress such desires, to put them out of mind, and to forget them. In the vast majority of instances such efforts are successful. The undesirable tendency is pushed into the unconscious, and the individual forgets that he ever had it. It is this controlling, suppressing, and forgetting that constitute Freud's "repression."[3]

Repression may act not only upon wishes and desires but also upon any unpleasant idea or disagreeable memory, and particularly upon those ideas that contain for the individual an element of reproach. Normal people do not lack self-respect, for, thanks to repression, they are serenely oblivious to most of their transgressions. In the lives of even the very best of us there has been such a multitude of unworthy acts, base desires, and regrettable incidents of which we seldom think, that if we should suddenly become conscious of them all we would feel ourselves, literally, "too mean to live." Repression defends us against such reflections, enables us to ignore unpleasant facts about ourselves and to preserve our self-esteem. As has been indicated, young children do not repress, but all adults do, and a great part of the forgetting of both normal and neurotic individuals is due to this mechanism. In normal individuals ideas once repressed manifest themselves in consciousness only rarely, as in dreams or symbolic acts, but under certain circumstances in predisposed individuals a failure of repression may occur, and the repressed desires may become active as symptoms in hysteria or obsessions. The wishes that obtain imaginary fulfillment in night dreams are *repressed* wishes nearly always. Freud is of the opinion that no unrepressed wish can produce a dream unless it gains associative connection with, and awakens to activity some repressed infantile idea. He admits that frequently such connection cannot be demonstrated and that this can by no means be absolutely proved. Somatic conditions probably do not cause dreams but only contribute dream material. The inciter of a dream is always a wish.

Wishes that may become dream sources may be divided as follows: (1) Wishes that originate during the day and remain unfulfilled by accident, either because they are crowded out of mind by other things which absorb the attention or because they are incapable of gratification on account of their nature. Little annoying problems of everyday life, and all sorts of unpleasant situations, are taken up in dreams and so worked out that the dreamer is relieved of any unpleasant emotion he may have had. Things unattainable during real life may thus be possessed during sleep and the dreamer escapes the annoyance of an unsatisfied desire and his sleep remains practically undisturbed. (2) Wishes that occur during the day and are rejected (repressed) for moral or similar reasons. These are wishes that are incompatible with the dreamer's ideas of his own personality, and which he refuses to entertain in order to preserve his self-respect. As may be expected, therefore, a great many of them are sexual. (3) Wishes that were conscious in infancy and early childhood and later repressed. These are brought into dream-forming activity by some occurrence during the day. These repressed infantile wishes are extremely important from a medical standpoint, but the subject is too extensive to be discussed here. It will be sufficient to say that in infancy there are sources of satisfaction which in later life are given up or become blended into the sex impulse. For instance, the infant derives great satisfaction from being naked. In normal adults the desire for nudity does not manifest itself in waking consciousness as a separate entity, though it is more or less connected with sexual desire, but it does appear in the perversion known as exhibitionism, and it gives rise to the dream of appearing among strangers scantily clothed. This dream is a very common one and nearly all people have it at one time or another. This same infantile desire may also find gratification as a symptom in the psychoneuroses though in an indirect manner. For further discussion of this subject see the works of Freud and especially his "Three Contributions to the Sex-

*Freud uses the term "conscious" to indicate all the mental processes of which we are aware at any given moment. "Fore-conscious" (Vorbewusste) denotes mental processes of which we can voluntarily and spontaneously become conscious, and "unconscious" mental processes which the subject cannot spontaneously recall to consciousness, but which can be reproduced by special devices. (Compare Jones' "Freud's Theory of Dreams.")

ual Theory."[4] I simply wish to point out that there is an important relation between dreams and the psychoneuroses, for they may both have the same origin, namely, the repressed wishes of infantile life, and thus the analysis of such dreams forms a prominent part of the psychoanalytical treatment of these disorders. A fourth class of unconscious wishes might be made of those desires that arise during sleep, such as thirst and the desire for micturition. These are the so-called "convenience dreams" and belong with the somatic dreams which will be mentioned later.

Now, as has been said, night dreams are the imaginary fulfillment of wishes that are excluded from consciousness. This exclusion is accomplished by a certain force, that of repression, and the wishes can enter consciousness and find imaginary fulfillment only when the repression fails or is relaxed. During the waking hours repression is strong and the exclusion is generally perfect, but in sleep it relaxes and allows the repressed thoughts to enter consciousness and manifest themselves as dreams. The vigilance of this guard is merely diminished, however, and it permits the excluded thoughts to pass only when they are so disguised and distorted as to appear unobjectionable. What Freud calls the "latent content" of the dream, that is, its true meaning, can only be obtained through psychoanalysis. It remains unconscious and that incomprehensible phantasy which we remember on awaking, the dream story or "manifest content," is an indirect, condensed, eugraphic expression of it. Repression acts as a censor and the latent thoughts of the dream are permitted to express themselves only by suggestion, implication, symbolism, or innuendo. The dream then represents a compromise between two opposing psychic forces—the repressing force which seeks to repudiate the wish and the repressed stream which seeks wish-fulfillment. In the dream both are satisfied in a measure. The repressing stream can tolerate the repressed ideas because they are so veiled that their true meaning is unrecognized and it can still deny their existence. The wish in the repressed stream reaches consciousness and finds fulfillment but is forced to assume a modified form. Further conflict is thus avoided and the dreamer continues to sleep.

The amount of distortion and censoring which the latent dream-content is made to undergo varies directly with the amount of repression. In young children there is little or no repression, and so there is little difference between the manifest and latent content of their dreams. The dream of a child can be recognized, often without analysis, as a direct fulfillment of an unfulfilled wish of the preceding day. In some dreams of adults that result from desires arising during sleep, such as the desire for micturition, there is little or no repression and hence little or no distortion. Whatever repression becomes attached to such wishes is thought to be derived from some associated repressed infantile idea.

The conversion of the latent into the manifest content in dreams is accomplished by the "dream work" (*Traumarbeit*) through four different mechanisms,[5] the first of which is *condensation*. This is brought about by fusion of memory pictures of different scenes, persons, or objects into single pictures. Fragments of different scenes may be united by a sort of mosaic formation into a single scene, or two scenes in a dream may be superimposed, as when two pictures are taken on the same photographic plate. The apparent absurdity of these pictures disappears when their origin is discovered. Symbolism is a favorite method of condensation. The second mechanism is *displacement*, that is, elements which are of minor importance in the latent content appear prominent in the manifest and *vice versa*. Displacement of the affect may also occur so that in the dream a certain emotion appears to be caused by one object when in reality it originates from another. There is never any actual distortion of the affect however. It may be displaced or diminished in intensity but it is always in perfect keeping with the latent thought, no matter how absurd it may appear in the dream itself. The third mechanism is called *dramatization* and deals with the method of representing the latent thoughts in the dream. In what we ordinarily call the dream, the manifest content, there is no intellectual activity, it is merely a collection of sensory pictures which are selected from the latent content by the action of the censor. The censor may be compared to a sieve in which the complete story in latent content is placed. Certain elements are allowed to pass through this sieve and these form the manifest content of the dream. In other words, all the thinking has been done before the sifting process, and any products of logical intellectual activity that may appear in the manifest dream were formed in the latent content and sifted through. These sifted sensory pictures are rendered objective and are comprehended by the mind as something witnessed, just as an actual event of waking life. The story in the latent content is therefore represented in the dream in the same manner that a story is expressed in pantomime or by a vitascope, it cannot be told, it must be *pictured*. Though spoken sentences or phrases often appear in dreams, as a rule they must be regarded as auditory pictures of something the dreamer has actually heard, and which have sifted through the censor. Freud compares them to the old cartoons in which the artist indicates the thoughts or words of any character by printing them in the picture with a line drawn around them connecting with the person's mouth.

Inasmuch as the latent thoughts are restricted to this one method of expressing themselves and the story can only be indicated by depicting it as something that is occurring; the past, the future, the present, and the subjunctive are all represented the same—in the present. As in a play, the representation of events which may have spread over months or years consumes only a few moments. This method of representation also imposes certain limitations upon the ideas that can be represented. Such meanings as "because," "when," "like," etc., are difficult to represent in a picture, and can only be expressed in a roundabout manner. In the dream, therefore, temporal or causal relation is shown by picturing the subordinate clause as an introductory dream and the principal clause as the main dream, or by allowing a scene representing the one to change into a scene representing the other, etc. The thought that "X" is like "Y" may be expressed by depicting "X" as "Y." The fourth mechanism is that of *secondary elaboration*. It includes those additions, modifications, and omissions that are produced after the dreamer awakes. The waking mind has a tendency to change the dream into a more complete and orderly story with a certain amount of logical sequence. Furthermore, those parts of the dream where the disguise is weakest are subjected to further distortion and these parts also are the ones that are first forgotten. It will be seen that the action of all four of the dream-mechanisms assists

the censor in the work of disguising the latent content of the dream.

The material of which the manifest content of dreams is formed is taken from the thoughts that occupied the mind of the dreamer during the preceding day. Prince[6] believes that the dream material is, for the most part, selected from those thoughts that drift through the individual's mind in that hazy state that immediately precedes sleep. Considerable of the dream material is made up of ideas, occurring during the day, which occupied the person's attention only for a moment, or which formed in the "penumbra of consciousness," so to speak, and were forgotten immediately. Pictures of more or less remote events appear in dreams, but as a rule it can be found that some time in the preceding day they passed through the dreamer's mind. Somatic stimuli such as noises, pain, etc., may contribute material which is used in the dream formation in the same way as psychic material.

The source of the latent content, as has been indicated, is quite different. The dream inciter is always a repressed wish. According to Freud, no unrepressed wish can become somnifacient unless it becomes connected with some infantile repressed idea. It therefore follows that the dream may mean the fulfillment of two wishes, an infantile and an adult one, and may become, as Freud expresses it, "overdetermined." Practically every element in the manifest content is also "determined" by several elements in the latent content, so that in analyzing the manifest element one finds that quite a number of different ideas contribute toward its formation. It is commonly supposed that various bodily conditions and physical stimuli are frequent dream sources, but Freud finds that such is not the case. The traditional Welsh rarebit has been unduly maligned. Somatic stimuli may furnish material which is fitted into the dream in the same manner as psychic dream material, but such stimuli alone cannot become dream inciters. The source of a dream is always a wish.

The function of the dream is the conservation of sleep. It completes various unfinished psychic operations of the day, that if left incomplete would be sufficiently disturbing to keep the individual from sleeping. It stills and satisfies repressed desires without allowing them to annoy the sleeper to any great extent and without permitting him to become conscious of them. In the so-called "fear dream" it fails in its duty, to a certain extent, for such dreams occur when the vigilance of the censor is so relaxed that there is imminent danger of the latent thought reaching consciousness with insufficient disguise. The effect of fear, however, takes the place of the censorship and awakens the sleeper just in time to prevent him from becoming conscious of the repressed idea. Analysis of such dreams indicates that they are always of sexual origin and the affect was once a sexual one but has been so modified as to manifest itself as anxiety. These dreams are, of course, incomplete.

The analysis of a dream seeks to retrace the lines of association from the different parts of manifest content back to the various thoughts from which they are derived. As has been said, each element in the dream is determined by several in the latent content, so in conducting an analysis one first divides the dream into its several elements and then asks the dreamer to tell whatever occurs to him about each single element in turn. In this way one awakens the associations from which the different dream pictures are derived and, when the origin of each of the separate elements is brought forth, it is a simple matter to piece together the scraps of information thus obtained and to discover the true meaning of the dream. In collecting these associations it is usually necessary for the subject to assume a state of abstraction, as by this means repression is to some extent relaxed. He is directed to fix his attention on one of the dream elements and then let his mind wander from it at will. He must wholly abandon any tendency to direct or criticize his thoughts and must relate everything that occurs to him. Nothing must be kept back no matter how unimportant or how unpleasant it may seem. "It is an error to believe that the activity of association, when left free, is devoid of any regulation by law. As soon as, during the analysis, we disregard the conscious terminal idea of our thinking the directive forces of the unconscious psychic activities prevail in the choice of associations, that is to say, the same mental forces which functioned in the creation of the dream"[7] become operative, and we are led back along the same paths through which the manifest thoughts emerged. The information thus obtained is never trivial. It deals with the person's inmost secrets, and reveals to a surprising extent the influence of the sexual and of the infantile on adult life. The latent content is always logically formed and perfectly coherent. In analyzing one's own dreams it is best to write down the associations that are awakened by the separate elements, as by so doing, it becomes easier to disregard the dream as a whole and to limit one's attention to a single element at a time.

The analysis of the following dream illustrates many of the points upon which we have touched. It shows the fulfillment of a wish and also several of the methods by which the latent thought expresses itself. Indirect suggestion, symbolism, substitution, condensation by fusion of scenes and of words, and displacement appear. The special devices of the third mechanism are illustrated, time relation is shown by having the subordinate part of the dream precede the main dream and similarity is expressed by identification. The influence of the infantile wish could not be demonstrated. The report of such an analysis is somewhat misleading for it would require too much space to record verbatim the mass of intermediate and more or less irrelevant associations that were brought forth. Only material closely related to the dream theme is given here. It required about four hours to make this analysis, though the report of it can be made in a few minutes. The dreamer is a normal young man about twenty-eight years of age. He related the dream as follows:

"I seemed to be dressed in a frock coat and was going to X-ville with Miss Blank. We stood outside a house and upon looking in through an open door I saw my brother standing beside a table on which was a pan of popcorn. I went in and shook hands with him and he said, 'have some,' and then 'there isn't any,' and when I looked in the pan I saw that it was empty. Then he said, 'Is Moestein going with you?' I think he meant Miss Blank and referred to my going to X-ville."

Analysis: Miss Blank, the dreamer stated, was the young lady to whom he had recently become engaged. Asked about X-ville, he said: "I've never been in X-ville with my fiancée, but I used to go there often to visit a friend of mine named Will Blank. I know several people there named Blank,

but they are not related to my fiancée, though the name is the same. She comes from Dashtown and most of her people live there. I expect we'll go to Dashtown to be married." "Going to X-ville with Miss Blank" may be interpreted as follows: X-ville and Dashtown are both places where the dreamer has acquaintances named Blank. In dreams there appears to be a failure of discrimination between ideas possessing similarity,[6] and so X-ville may really represent Dashtown, simply because the two places have similar associations in the dreamer's mind. Such substitutions are extremely common in dreams. The dreamer expects to go to Dashtown to be married. If one now substitutes Dashtown for X-ville, "Going to X-ville with Miss Blank" may be taken to mean "I am about to be married" or something similar, and this phrase seems to be some sort of a subordinate clause introducing the main part of the dream. The frock coat bears out this conclusion, for, when asked what it suggested to him, the dreamer said: "I don't like to wear a frock coat and Miss Blank knows this, but a short time ago she said: 'Well, you'll have to wear one at our wedding, won't you?' and I promised that I would." The frock coat is therefore a symbol of his approaching marriage. The house he saw in the dream he recognized as the one where he had spent Christmas with his brother, and he recalled that he had seen popcorn in a pan on that occasion. He also said: "I had an awfuly pleasant time there, I had a long talk with my brother and he spoke very nicely of Miss Blank and this pleased me immensely. He has always liked her." Of his brother he said: "In the dream he didn't look quite natural, his face was rather red and he stood up unusually straight. This, and the way he shook hands with me, seems to remind me of someone else, but who it is I can't recall." I took this to be an important part of the dream and urged the dreamer to try to recollect who it was that his brother's appearance suggested to him, but his efforts were unsuccessful until later. The disappearance of the popcorn and his brother's phrases, "Have some" and "There isn't any," also failed for some time to bring forth anything of interest. Freud says that when anything is spoken in a dream it usually means that the dreamer has actually heard the same or similar words spoken when awake. It was after I had told him this that he recalled the following episode: "I went to see my friend A. last week; there was a box of candy on the table and as I entered the room A., pointing to it, said: 'Have some.' Then he opened the box and, to his surprise finding it empty, exclaimed: 'Oh, there isn't any!' A. has a red face and is very straight. He shakes hands as my brother did in the dream and it is he of whom I was reminded. It's queer that I didn't think of him before."

The "brother" in the dream appears to be a composite picture of the dreamer's brother and his friend. Upon my asking for more information about A., the dreamer replied: "He is my best friend and I think a great deal of him. At one time we were almost inseparable and of late a little feeling has arisen between us and I don't see as much of him as I used to." When urged to give a reason for this change he showed considerable hesitation but finally explained as follows: "As I said, I have only recently become engaged to Miss Blank, but I've been fond of her a long time. I used to talk to A. about her a great deal and he always appeared interested and sympathetic, but it so happened that he never met her until three months ago. I had been very anxious that he should know her and like her, as of course I expected he would, but when they did at last meet I was greatly hurt and disappointed to observe that he did not like her at all. Since then he has hardly spoken of her, though, as I said, before this we used to talk of her often. He has never inquired how my affair with her was getting on and, though he knows that I go to see her often and must suspect that we are engaged, he has never asked if we were to be married and I have never told him. I would have enjoyed it very much if he and Miss Blank could have liked each other and been friends. Of course, it's nobody's fault that they can't, but I think that A. might at least have shown interest enough to ask if we were to be married. All this, of course, is what caused the trouble between us."

The meaning of the popcorn scene now begins to appear. It is a combination of two scenes and two persons. The scene in which the dreamer spent Christmas with his brother is combined with the scene of the candy episode with his friend. The Christmas scene, in which Miss Blank is spoken of with affection and esteem, is in direct contrast with the other, where all mention of her is avoided. The first scene forms the antidote, so to speak, for the second. In the dream A., who does not like Miss Blank, takes the form of the brother who does. Identification is the usual method of expressing similarity in dreams. The meaning of this part of the dream is, assuredly, "A is now like my brother," *i.e.* he likes Miss Blank. The phrase, "Is Moestein going with you?" recalled nothing to the dreamer. He was certain that he had never hear it or anything similar before, and we finally concluded that it must have some other origin. When asked if the word "Moestein" suggested anything to him, he replied: "No, except that it seems to be a Jewish name." Later he recalled that on the evening that he had had the dream he read in a newspaper that Moe Levy & Co. were about to dissolve partnership. The same evening he had also read in the *Saturday Evening Post* a story in which one of the characters was named "Beekstein." "Moestein" is a synthesis of "Moe Levy" and "Beekstein," and apparently is some sort of a Jewish type name. Neologisms formed in the same way are familiar in dementia precox. When asked if any Jewish name had a significance for him, he immediately recalled that one of his friends had a small sister who was called "Maruschka" as a pet name, and he had always supposed the word to be Jewish. The connection is evident. Jewish names and pet names are associated in the dreamer's mind; in a way they are lumped together in one class. The dreamer imagines that his friend speaks of Miss Blank by a name that belongs to this Jewish-pet-name class; in other words, he refers to her by a term denoting brotherly affection. "Is Moestein going with you?" (to X-ville) means, of course, "Are you going to be married?" The dreamer has desired that A show more interest and ask this question, and in the dream his wish is fulfilled. The first part of the dream can be taken as a subordinate clause introduced by "when," as this is the usual method of representing time relation, and the meaning of the whole dream is something like this: "When I am about to be married my friend likes (or will like) Miss Blank as my brother does. He shows his interest by asking if we are to be married, and indicates his feeling toward her by speaking of her by a term of brotherly affection."

The next dream shows the value of dream analy-

sis as a therapeutic aid. The case was more of an anxiety neurosis than an hysteria. It does not show the influence of the infantile traumata, etc. Perhaps the information I obtained in this way could have been brought out, in time, by other means, but hardly with such ease and promptitude.

The patient, Mrs. D., aged 26, born in the United States, came to me last February with the following history: Her family and previous history presented little of interest. She was married at 18 and had three children, the last one a little over two years before. Up to the birth of her last child she had always been well, but it was soon after this that her present illness began. She then noticed that she was gradually becoming "nervous"; she suffered from insomnia, hyperacusis, attacks of vertigo and of palpitation, and a condition of general irritability. She had also lost some weight. Her most prominent and distressing symptom was that of anxiety. Though she had a tendency toward anxious expectation of all sorts of unpleasant things, her anxiety was chiefly directed to the welfare of her children. She could not bear to have them out of her sight for fear something would happen to them; the least cough or sneeze from one of them brought to her mind pictures of impending and fatal pneumonia, etc. These symptoms were evidently those of the anxiety neurosis as described by Freud. He says: "The anxiety neurosis is produced by all moments that impede the psychic elaboration of the somatic sexual excitement,"[9] such as coitus interruptus, voluntary abstinence, ejaculatio precox in the husband producing failure of orgasm in the wife, etc. I therefore ventured to inquire into her sexual life, in the hope of finding some such etiological factor. She stated that she and her husband had never practised coitus interruptus, nor had they employed any other means of preventing conception. She admitted that the marriage relations, since the birth of her last child, had been practised less frequently than formerly, but said, in explanation of this, that as she became nervous she found her sexual desire diminishing, and even to some extent lost her affection for her husband, so that the sexual act had become repellant to her. She finally confessed that she had been pregnant and had induced an abortion about eighteen months before. She had felt worse after that and at times thought that it had something to do with her illness. This loss of sexual desire is frequent in anxiety neurosis, and hence her statement did not shake my opinion that we were dealing with that disorder and that her symptoms were due to an accumulation of sexual excitement escaping as anxiety. Though I insisted that there must be something that caused insufficient gratification before she lost her desire, she could give no explanation and appeared to think my ideas were ridiculous, so I was forced to conclude that by direct questioning I could make no further progress. I then asked her about her dreams, with the idea that they might afford the desired information. She said that though she had dreams very frequently she seldom remembered them. She finally recalled one that had stuck in her mind because it seemed so strange to her. This was her dream: "I saw my father and my mother and several other people whom I knew to be my relatives. I had some sort of a club with a flat end, and with it I killed them all." The thing that seemed so peculiar to her about this dream was that she felt no particular emotion in it. She was very fond of her parents and on the best of terms with all of her relatives, and could not understand how, even in a dream, she could do such a deed and view such a scene without feeling horror and disgust. As Freud has shown, such emotional incongruity is only apparent; the emotion (affect) in a dream belongs to the latent content and is in perfect harmony with it. "The affect is always right."[10] So it was in this dream. Upon asking the patient to tell what her "club" suggested to her, she said: "It was red. It looked like red rubber. It was shaped something like a mushroom, but I've never seen anything exactly like it." A moment later she said: "I just thought of something, and though it isn't important, I may as well tell it, for you seem to want to know everything. I bought a red rubber catheter when I brought on my miscarriage. I have it still and saw it in a drawer recently." A little later she showed evidence of having thought of something that produced a certain emotional disturbance, and, after considerable urging, she related the following: "I just thought of a conversation that I had with my cousin about two years ago. She had been married about as long as I, but she had only one child. We were talking about that, and she said she used something she called a 'womb veil' to keep from having children. She said it was shaped like a mushroom. Perhaps that is what I saw in the dream." The thought of killing her relatives brought forth nothing of interest for some time. She stated that in the dream her father and mother were quite distinct, but the other people were not, though she knew them to be her relatives. At last she recalled this incident: "About two years ago I belonged to a Bible class that was taught by a doctor. He gave some 'talks to young wives,' which I attended. He said it was wrong to do anything to keep from having children, and that a woman who did such things or brought on a miscarriage was really a murderess, and just as bad as one who killed her relatives. I never knew much about such things, but somehow I didn't agree with him."

The meaning of the dream had by this time become clear to me. I told her what I thought about it; her resistance was broken, and I got the whole story. Her husband was very fond of her in his own way and, on the whole, her married life was quite happy. He was, however, a big, careless sort of man and had been pretty inconsiderate in many ways. He was especially unsympathetic when her children were born, and had seemed impatient with her and totally lacking in appreciation or understanding of the pain she had to endure. His attitude at such times had hurt her greatly, and, as she was inclined to brood over it, she developed a dread of becoming pregnant. She also felt that three children were certainly enough; for, as she expressed it, she did not want to become an old woman before her time; so, after her last child was born, she tried to induce her husband to take some precautions so that she might not become pregnant again. He would not listen to her request and acted in such an unreasonable and inconsiderate way that she never mentioned the subject to him again. Her cousin had mentioned a "womb veil" to her and she often wished she had one, but did not know how to go about getting it, and there was no one of whom she was willing to ask advice. Practically all she knew about sexual matters she had picked up from chance conversations, as she did not like to ask questions about such things. Up to her third pregnancy she had been quite passionate, and intercourse had been satisfactory in every way; but after that, on ac-

count of her dread of pregnancy, she avoided intercourse whenever she could. In addition, she had heard that orgasm was necessary for impregnation, so she endeavored to suppress her libido, and finally succeeded in doing so, and her desire almost disappeared. This, then, was the etiology of the neurosis. Voluntary repression had interfered with the psychic elaboration of somatic excitement and caused an accumulation which began to manifest itself subcortically as anxiety. When the somatic excitement had once begun to escape by this route there was continually less tendency for it to become transformed into psychic sexual excitement, and the libido appeared correspondingly diminished. The meaning of the patient's dream is evident. The killing of her relatives stands for the prevention of conception, and the "club" is a combination of catheter and pessary, and so an instrument of prevention. She dreams that she prevents conception, hence her libido need no longer be suppressed and her erotic wishes may be fulfilled. Her anxiety had been chiefly concerned with the welfare of her children. As Brill remarks, "To those acquainted with the language of hysteria such things frequently mean the opposite."[11] Such was the case here. Her anxiety about her children was a compensation for her wish to have no more children, or that she had none. Her abortion became a source of worry and self-reproach, and contributed to her nervousness and depression. The treatment of this case consisted in explaining to her the origin of her symptoms and giving her a little advice. I saw her again within a week and she stated that she felt considerably better, that her mind was relieved, and that she thought she was going to get well. She was directed to return in a few days, but she failed to do so, and I did not see her until nearly three months later. She then reported that after the analysis her symptoms began to disappear, and in less than a month she felt perfectly well. Her normal sexual feelings and her affection for her husband returned and she gained six or seven pounds in weight. She has remained well ever since.

Theoretically, the value of dream analysis as a psychotherapeutic aid is enormous. The psychoneuroses, hysteria and the obsessions, according to Freud, are produced by the activity of repressed infantile desires. The symptoms are a result of a partial failure of repression, which permits the repressed desires to return to consciousness and obtain symbolic gratification. The origin of these desires has been discussed; they are the wishes of the third class that enter into dream formation. The failure of repression is generally brought about by some later psychic trauma. Freud's therapy consists in making the patient conscious of all the events, desires, etc., that led to the development of his neurosis. When this is done, and a discharge for the pent-up emotivity is afforded in speech, the symptoms disappear. The patient may learn some disagreeable facts about himself in the meantime, and may become sensible of some rather unflattering desires; but as these desires are now conscious they can be influenced and controlled, while before they were out of reach and, in a way, influenced and controlled him. Now these same wishes and cravings that cause the neurosis also become dream sources, and by analysing such dreams one arrives at the repressed ideas that cause the neurotic symptoms, and the analytical cure is greatly facilitated.

Opinions as to the practical value of dream analysis vary greatly. Freud, Jones,[12] Brill,[13] and Scripture[14] consider it the most valuable psychoanalytical procedure, "the *via regia* to the understanding of the unconscious." Jung,[15] Ferenczi,[16] and Putnam[17] all speak of it in the highest terms. Prince[18] disagrees with Freud in some particulars, but considers dreams well worthy of study. Meyer says:[19] "There is no doubt that dreams express much more directly and uncritically the trend and bend of our imagination than anything we expose in our more circumspect waking thought." Others condemn Freud and all his works without reservation and consider dream analysis "not only baffling and valueless," but "positively harmful."[20] They not only reject dream analysis, but psychoanalysis as a whole. "Older methods are more satisfactory and more decent."[21] My own experience convinces me that psychoanalysis justifies itself, and that if one conscientiously practises it for a reasonable length of time he cannot fail to be convinced that it is of the utmost value as a therapeutic agent. As far as I am aware, those who accept Freud's psychoanalysis accept dream analysis also, and regard the analysis of dreams as an important part of psychoanalysis in general, and as something inseparable from it. A criticism of one is, in general, a criticism of both. The technique of dream analysis is the same as that of analyzing symptoms, and I doubt if one can analyze the neurotic symptoms without having mastered dream analysis also. Freud says: "If I were asked how one could become a psychoanalyst, I should answer, through the study of his own dreams."[22] And it is my experience also that nothing else gives such good practice for psychoanalysis. Familiarity with the "typical dreams," those that mean the same in all people, is valuable even outside of psychotherapy. Many cases can be completely analyzed without recourse to the patient's dreams, but in some difficult cases dream analysis affords the only efficient means of penetrating into the unconscious mind and bringing the pathogenic complexes to light. The technique of analysis of dreams is not easy, and it is a procedure that requires a good deal of time, but my experience is that it fully repays the time and trouble spent on it.

I cannot help feeling that a great deal of the criticism that has been made against psychoanalysis is very superficial, and that much of it has been made by men who have had absolutely no practical experience with the method they criticise. I am inclined to suspect that a great number of those who condemn Freud either do not read him carefully, or, having read, feel "disinclined to follow a leader who ascribes a sexual symbolism to such innocent objects as blossoms and branches of trees,"[20] and therefore do not put his teachings to any practical test. The prominence of the sexual in Freud's works does not appeal to the esthetic mind, but it is rather unfair to the sick to refuse to investigate a method of therapy for that reason. Were we to restrict ourselves to methods of practice that presented a purely esthetic appeal, obstetrics, for instance, would receive a hard blow. If one attempts to practise psychoanalysis he will soon be convinced that it is the patients rather than Freud who are responsible for the emphasis that is laid upon the sexual. The psychology of the sexual forms the theme of nearly every novel, poem, and drama, and it is singular that one should be startled and shocked by the idea of including such a topic in medical literature. That delicacy which overlooks the strongest impulse in nature and exalts

such factors as eyestrain, adenoids, and dietetic errors to extreme etiological importance in psychic disorders, is, no doubt, well meaning, but extremely shortsighted. Freud's method is an attempt to treat abnormal psychology by psychological means, and this ought to recommend it to the unprejudiced, for it is certainly more logical, though perhaps less agreeable, than prescribing a course of tonics and baths.

It is true that Freud and his followers have made errors, and it is certain that the last word on psychoanalysis has not yet been said, but it is equally true that they have presented us with a method of treatment that promises much, that appears to have cured many, and that deserves investigation. There are few who doubt that psychoanalysis cures some cases, for we have testimony to that effect from men whose veracity and soundness of judgment are unquestioned; it remains to be seen in what percentage of cases it is successful, and how this percentage compares with older methods of treatment. This can be established only by statistical reports from a large number of unprejudiced observers who follow out the technique carefully and consistently, and who record both failures and successes. If this is done, I think it will be shown that the importance of the sexual has not been overestimated and that the method of psychoanalysis is a most valuable addition to our therapeutic armamentarium.

FUNCTIONAL SEXUAL DISORDERS PROCEEDING FROM THE GENITO-URINARY TRACT.*

BY TERRY M. TOWNSEND, M.D.,

AND

JULIUS J. VALENTINE, M.D.,

NEW YORK.

A COMPLETE understanding of the problems involved in aberrations and disturbances of the genesic function in the male requires intimate knowledge of psychology, psychopathology, and familiarity with the physiology and pathology of the genito-urinary system. Such vast knowledge has been denied the authors, and in presenting this subject indulgence is craved. Within small compass, the essential points will be reviewed, to which will be added some personal observations and deductions. Therefore, in attempting to cover, in a few moments, a field which merits years of study, let judgment rest upon the sins of commission and not of omission.

It is admitted that self-preservation is the most powerful natural instinct, self-propagation, through sexual intercourse, the second, and love of offspring, the third. The first and last may exercise their influence at times, but sexuality is constant. It is upon this instinct that almost all ethical and individual qualifications are founded. Even that most sacred safeguard of the marital tie, the Roman Catholic Church, permits the declaration of nullity of marriage, if it can be proven that (1) impotency existed prior to marriage and (2) that it is incurable.

It is easily conceivable how a disturbance of the delicate adjustment of this powerful primal force means more to a man than a long series of disorders in other regions and why its restoration to functional ability is of great moment to the sufferer. Perversions of the function are not rare, yet these obliquities no more signify the disappearance of the instinct than a river outside its usual channel means the drying up of the river.

The period of male copulative power is usually between the eighteenth and sixtieth year, this being relative rather than absolute. The frequency of the act is so dependent upon the personal equation that no formula has ever been expressed. Neither has there been satisfactory proof presented that ill effects follow reasonable frequency or total abstinence. We have observed one individual infected with chronic gonorrhea who claimed to have copulated each night for twelve years except in those periods when his wife was menstruating.

Nocturnal seminal emissions occur in celibate men at varying intervals. Rothschild[1] prudently mentions eight, ten, or thirty days as the usual interval. These are physiological, except when the intervals are unusually short or when undue lassitude or mental excitation follows.

If an individual possesses normal penis, testicles, prostate glands, vesicles, and vasa deferentia, he must also possess the libido sexualis for the performance of the sexual act. The nerve centers of this part of the system are located in the cerebral cortex; those of erection and ejaculation in the cord. For perfection of the function, they must all respond to stimulation harmoniously. However, they may functionate independently, thus, a nocturnal

*Presented before the Genito-Urinary Section of the N. Y. Academy of Medicine, December 21, 1910.

pollution without an erotic dream signifies the sole action of the centers of erection and ejaculation, whilst intense excitement without erection or ejaculation indicates cerebral action without sufficient irritation of the centers in the cord to produce ejaculation. Likewise, they may suffer independent pathological changes.

Finger[2] classifies types of impotence into (1) those which have cause in palpable and demonstrable pathological tissue changes and (2) those in which no anatomical or pathological changes are known.

Among the causes of impotency of the first type are (*a*) Mechanical obstacles such as very large hydrocele, large tumors of the testes, injury or loss of the penis or testicles, shot wounds, ulcerative destructions, and new growths of the penis, such as cancer, venereal warts, and elephantiasis of the genitals. Varicocele, chronic epididymitis, and atrophy of the testicles diminish or dissipate sexual desire and ability, probably due to lack of nutrition in the organs together with trophic nerve changes. The loss of the testicles undoubtedly causes impotence, but not as rapidly as supposed, as proven by Sturgis,[3] who quotes one observation where the patient was virile for at least two years following ablation of these organs.

Copulation may be impossible because of interference with the mechanical factors concerned in erection. Deep traumatisms of the corpora cavernosa from urethrotomy, fracture of the organ, or the formation of fibrous or so-called calcareous plaques may cause obliteration of the venous sinuses, which, if sufficiently extensive, prevent erection of the distal portion of the organ. Lydston[4] believes arteriosclerosis with its preceding history of dietetic and alcoholic excesses to be a factor in circulatory changes in the vessels of the penis. He relates a case of a man of sixty years with no venereal history, but pronounced arteriosclerosis. Examination showed marked sclerosis of the corpora cavernosa and the formation of a fibrous cord in the corpora. Sexual powers gradually diminished and disappeared.

(*b*) Faulty or absence of erections through disease of the centers of erection or the nerves conducting thereto. Disease of the peripheral nerves is the most common factor in this etiological class. Any injury or disease of the nerves leading to the erection center may disturb the sexual balance. Schulz's case, quoted by Finger, is a striking example of this fact. Dorsal incision of a phimosed prepuce was performed on a young man. Shortly thereafter the patient found himself impotent. Examination showed anesthesia to electric stimulation over the major portion of the dorsum of the penis and flaps of the prepuce. Cure was attained through galvanization of the anesthetic area.

More frequently the disturbance of the afferent nerves has its origin in the posterior urethra and the colliculus seminalis. That the colliculus plays an important rôle in the sexual act is beyond doubt, even though its exact physiology is not understood at the present time. This is proven by the frequent erections during acute posterior urethritis, the full or partial erection subsequent to instillations of silver nitrate into the posterior urethra, the tendency to erection or emission following instrumental ingression into that region, and the morning erection when a full bladder is distending the posterior urethra. It is also a clinical fact that the majority of cases of sexual disturbance show pathological changes in the colliculus or its adjacent mucosa.

The causes of colliculitis are masturbation, sexual excesses, habitual coitus condomnatus, coitus reservatus, coitus interruptus, and chronic posterior urethritis. These irregularities exercise their dire influence on the sexual organism by causing highly increased sensibility of the posterior urethra, passive congestion of the colliculus, and ultimately an inflammatory infiltration enclosing the terminal nerve endings. Thus, through continuous irritation of the erection center they bring about a state of anesthesia or exhaustion. Posterior urethroscopy in these individuals discloses, in practically every instance, hyperesthesia, sodden mucosa, maceration of the tissues, enlargement of the colliculus, and not rarely papillary irregularities.

These papillary irregularities, as well as regularly formed new growths in the deep urethra, may give origin to sufficient irritation to cause frequent and prolonged erections. These erections are painless and unassociated with sexual desire. In fact, sexual intercourse and seminal emissions do not influence their course in any manner.

Masturbation is a less important factor in sexual disorders than is generally credited. Young men who masturbate usually cease the habit when they learn of its moral degradation or when they arrive at discretionary years. Those who continue the habit as adults are sufferers from psychic paresthesia, which is beyond the bounds of this paper. The "mental masturbation" of Curschman unquestionably causes hyperemia of the genital centers. The predisposing causes of this condition may be reflex, from such peripheral excitants as phimosis, calculi in the lower tract, etc., or the subject may possess through heredity a mentality so degenerate that only the physical and not the esthetic pleasures appeal.

Coitus interruptus or reservatus and protracted coitus are prolific causes of peripheral irritation. These first two irregularities are practised by men to avoid impregnating their sexual partners; protracted coitus to intensify or allow repetition of the female orgasm. These men know not that they are guilty of sexual misdemeanors and only receive enlightenment when sexual decline sends them to a physician.

The damage arising through these practices may be explained by the fact that prolonged turgescence of the penis together with the wilful delay of that normal nerve explosion coincident with ejaculation leaves the posterior urethra and prostate in a state of venous stasis. Many times repeated, this stasis is followed by a plastic exudation into the submucous fibrous tissue, which in turn becomes a fibrous infiltration.

Coitus condomnatus is less frequent etiologically, though by no means negligible. Theoretically, by lengthening the act it becomes a modified coitus reservatus.

The most common cause of posterior urethritis and colliculitis is chronic gonorrheal urethritis. This is because of the frequency and obstinacy of the infection and its insidious and treacherous character after invasion of the adnexa. Fuller[5] pointed out in his studies on seminal vesiculitis the prevalence of impotency or impairment of sexual vigor in sufferers from spermatocystitis. The verity of his deductions has been amply proven in succeeding years Fortunately, the seminal vesicles are infected in the minority of chronic gonorrheas.[6] This is not true of the prostate, since it is the rare exception that it escapes damage. This "sexual heart . . . has

nothing to do with urination . . . but toward the sexual function it acts as a muscle, a sensory organ, and a gland." (Keyes.[7])

Manifestly, any disturbance with its functions through plastic exudations or fibrous tissue proliferation will be reflected in the sexual act. It seems to play a greater part in irritable weakness than in complete impotency, since it has been often observed that the most troublesome gland may cause less sexual deficiency than a slightly involved colliculus.

The symptomatology is so full and varied that the barest synopsis can be presented. It is necessary to study the patient's character, habits, modes of life and thought, as well as the character changes wrought by his sexual illness, to determine in what degree the complaints are due to physical changes and which are psychic.

Posterior urethritis with involvement of the colliculus is accompanied by a train of subjective symptoms which have been grouped by less astute observers under the ubiquitous term of neurasthenia. These symptoms are headache, backache, discomfort in the perineum, pelvis, and thighs, lumbago, anorexia, lack of energy, mental lapses, and loss of ability for mental concentration or effort.

This symptom complex is explained by Finger[2] by the fact that the sympathetic hypogastric plexus is in intimate association with pudendal and sacral plexuses and therefore the lumbar nerves, and being strengthened by fibers of the sacral and pudendal plexus, innervates through the vesical plexus, the bladder, seminal vesicles and prostate. In this manner it happens that when the terminal nerves of the prostatic urethra are kept in a state of continuous irritation by chronic inflammatory changes, this irritation may affect other nerves joining with the above-mentioned plexuses. Neuroses of different kinds may thus arise in the whole genitourinary system, first localizing as sexual neurasthenia and from there gradually spreading and extending to spinal or even cerebral neurasthenia.

Prostatorrhea and spermatorrhea are occasional symptoms and are accorded much more importance by the patient than they deserve. Ejaculatio præcox is an early symptom and varies in severity from ejaculation after the first few intromissions to ejaculatio ante portas. Hemospermia, usually accompanied by cutting or burning pain at the acme of the act, is a familiar symptom when both prostate and vesicles are involved. The pain or discomfort during ejaculation, when not directly due to acute inflammation, is caused by infiltration or stricture of the distal portion of the ejaculatory duct.

The establishment of the urinary stream is retarded and the coup de piston is weak. Patients complain of this lack of expulsive power because of the annoying urinary after-dribbling. When the stream is interrupted, as in the sectional beaker test, pain and even mild bleeding have been observed. In cases of irritable weakness, the genitalia are hyperesthetic, while in those of absolute impotence the opposite is true. Urethral hyperesthesia, with marked intolerance to instrumental examination and a tendency to bleed at the slightest contact of the tube, is such a common symptom that when observed on the examination table it prompted questioning concerning the patient's sexual habits with special reference to coitus interruptus and condomnatus.

Through the urethroscopic tube the posterior urethra presents a striking picture. The mucosa is swollen, macerated, shining and congested. The slightest movement of the tube provokes oozing, the walls may be slightly irregular and the openings of the ejaculatory ducts, if visible, appear swollen and pouting. Examination is so painful that it must be hastened.

The diagnosis of sexual debilities and disturbances must rest almost wholly on the anamnesis, the facility or difficulty depending to a great degree on the personality of the patient. Frequently they resent too close or prolonged questioning regarding their sexual life, and as a rule decline to relate full histories in the presence of a third party, even an assistant or their attending physician. The classification of the case in accordance with its etiology is more difficult and many times requires study and observation of the patient.

As a basis for the statistical study of the subject, the records of 1,690 private patients presenting with genitourinary diseases were examined. One hundred and eleven were found to suffer from disturbances of the sexual function. The youngest was 18, the oldest 58, the average age being 35 + ; 68 were single, 43 married; 54 presented for consultation and examination and subsequent reports of their condition could not be obtained; 21 were cured in the course of treatment, 14 improved and 22 were unimproved after one month or more of treatment. In some cases the failure was distinctly due to disobedience of instructions with regard to drink and coitus. The length of time required for improvement or cure varied from three treatments to five years.

Number of patients giving history of gonorrhea, 52; number of patients giving history of masturbation, 24; number of patients giving history of coitus interruptus, 9; number of patients giving history of coitus condomnatus, 2; number of patients giving history of sexual perversions or peculiarities, 15.

Clinical and microscopical examination showed the number of patients showing pathological processes in the prostate by palpation, 86; in the seminal vesicles by palpation, 45; in the colliculus, 11; suffering from lithemia, 15; diabetes, 3; intestinal autointoxication, 4; showing irritation of the kidney, its pelvis, or catarrhal pyelonephritis, 27.

Microscopical examination of the urine sediments showed the presence of:

Urethritis in	19 cases
Prostatitis in	68 "
Spermatocystitis in	19 "
Pyelonephritis in	2 "
Chronic catarrhal nephritis in	1 case
Pyelitis in	1 "
Catarrhal cystitis in	8 cases
Lithemia in	15 "
Irritation of the kidney and its pelvis in	8 "
Oxaluria in	7 "
Phosphaturia in	6 "
Normal urine in	35 "
No urinalysis made in	3 "

This tabulation merits discussion before passing to the next point. It is remarkable to observe the large number of cases showing prostatitis by urine examination, which in conjunction with the physical findings by rectal palpation denote that prostatitis is a constant concomitant of sexual disturbance, it having been observed in the purely psychic cases where no infection had occurred.

Urethritis and seminal vesiculitis are but slightly more numerical than lithemia. The number of lithemia, oxaluria and phosphaturia cases is 28, which

points to a rather large number of instances of faulty metabolism in men actively engaged in work.

It is quite as difficult to classify sexual disturbances in a pigeon-hole method as it is to sharply define and differentiate other physical ailments. The following table, as indicated by Finger, is used and all possible care taken to avoid error:

Cases due to peripheral nerve irritation, 71. These were subdivided according to their concrete causes into: Chronic gonorrheal posterior urethritis, 20; chronic non-specific posterior urethritis, 16; masturbation, 19; coitus interruptus, 9; sexual excesses, 3; coitus per os, 3; coitus condomnatus, 1.

Irritable weakness	24
Epilepsy	1
Mechanical impotence (penile incurvation)	2
Diabetic impotence	3
Anesthesia of the erection and ejaculation centers	4
Hyperesthesia of the erection and ejaculation centers	4
Psychic anesthesia	10
Psychic parasthesia	4
Fear of failure	9
Anesthesia of the brain and cord centers	3
Relative psychical impotence	3
Sexual neurasthenia due to temporary paralysis of the cord centers from peripheral irritations	1
Senile prostatic hypertrophy	3
Malignant prostatic growths	1
Intestinal autointoxications	2
Psychic restraining center stronger than the exciting center	1

Contrary to the common acceptance that the Hebrew is more susceptible to neurotic disturbances, only 32 of the above cases were observed in Hebrews as against 79 in Gentiles. With regard to occupations,* clerks, merchants, tailors and commercial travelers are numerically greater.

When the sexual imperfection is secondary to mechanical impedimenta, treatment is necessarily surgical. A very large hernia, hydrocele, or new growth in a testicle may prevent coitus, but in no manner affect desire or potency. Curvatures of the penis may prevent coitus if sufficiently pronounced, but in this regard much can be accomplished by posturing. Partial erections of the proximal and flaccidity of the distal portion are extremely difficult or impossible to relieve. These cases have been subjected to dilatations over long periods without result. New growths of the glans and anterior

third of the organ may be removed and occasionally the sexual function may be preserved. Acton, quoted by Sturgis[3], relates a case history where loss of the glans by amputation caused no difference in the sensation accompanying the act.

Congenital or acquired malformations, such as epispadias, hypospadias, attachment of the penis to the scrotum, phymosis, and atresia of the meatus are amenable to surgical relief.

In the treatment of these diseases, abstinence is a *sine qua non*. When the psychic element predominates, failure accentuates the depression and more firmly fixes the idea of incompetence. Where the cause is peripheral nerve irritation, attempts at coitus or even sexual excitement aggravate the previous pathological conditions.

General tonics have long and justifiably held an important place in the estimation of our medical forefathers in the treatment. Many of these patients are physically below par and need systemic medication. Those who have no crying need for tonics are improved by their placebo effect and feel that every effort is being made for their relief. Ligation of the dorsal vein, mechanical apparatus, like the penis expander, and various prosthetic appliances, such as splints, and the much vaunted aphrodisiacs, lie at rest in obscurity for the reason that they were empiric, their *raison d'être* being based on false theories.

Physical exercise and hydrotherapy are worthy adjuvants to our local treatments, especially where the occupation does not oblige open air or a moderate amount of activity.

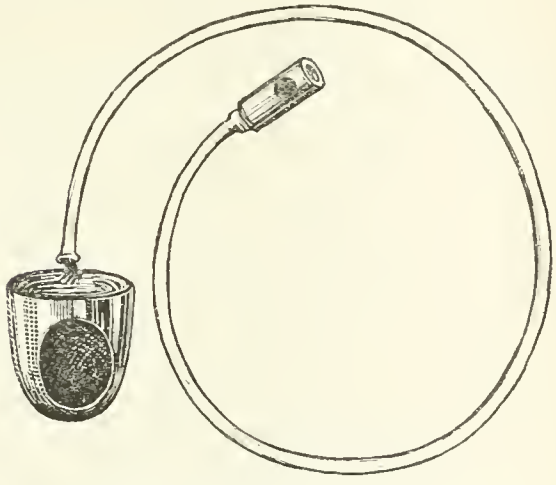
Removal of the cause, when the condition is not advanced and before extensive organic changes have taken place, will in numerous cases have curative action.

Impotence due to peripheral nerve irritations from the deep urethra, in which the prostate is invariably involved, are most amenable to treatment. Even though the palpating finger may not discover a prostatitis, the urine sediment will contain sufficient elements to deduce a mild inflammation. Upon these findings, massage of the gland is strongly indicated and is one of the most effective methods of treatment at our disposal. The treatment can be tolerated every fourth or fifth day. Improvement may be accelerated in some patients if an intravesical irrigation of an antiseptic solution is administered after the massage.

The application of faradism to the prostate and spinal centers has considerable value. Its beneficial effects are more apparent in atonic cases where defecation and urination prostatorrhea are symptoms. A practical method of applying the current is by the Dommer urethral and prostatic electrodes, one pole being attached to each instrument, or by using either instrument singly, applying the other pole over the spinal centers. The rectal electrode is concave with the metallic side upmost to send the current toward the prostate and seminal vesicles. The urethral electrode is the usual hard rubber sound with exposed metal at the posterior urethral curve.

The desire to combine prostatic massage with the electric current led Hogge,[8] and later Courtade, to devise electro-masseurs. Their instruments consist of a finger cot containing a metallic plate and a connecting wire. The objections to these instruments are their bulkiness and difficulty of sterilization. Hogge reported 96 cases cured or improved by this treatment. A simpler device was perfected

five years ago and ever since has given complete satisfaction. It consists of a metallic fenestrated thimble, with a cable and binding post.



Electromasseur, three-quarters actual size.

The prostatic psychrophore is an old and useful method of treatment. There are several models of the instrument, the most useful of which is one made of a large tube bent at right angles with out-flow and in-flow attachments and slightly broadened near the tip where it comes in contact with the prostate. The other models (Arzberger, Winternitz, etc.) are too short and small. Cold is usually employed, although good results are obtainable from alternation of heat and cold. For this method a special instrument is necessary. That of Shoenfeld is the best. The technique of its use is simple. The patient lies in a recumbent posture: the instrument, having been previously prepared by attaching the in- and out-flow rubber tubes, is inserted into the rectum and the siphonage established. Four quarts of water at the usual hydrant temperature are sufficient for the first seance. The length of the treatment may be increased by one quart at each visit. Beyond ten quarts there is no practical advantage.

Winternitz[9] describes the modus operandi of his instrument as follows: "Amongst the patients suffering from pollutions, spermatorrhea, many forms of impotence, precipitate ejaculations, incontinence of urine, chronic gonorrhea, and allied conditions, there is a great number in whom a relaxation of the tissues and muscles predominate. A relaxed scrotum, softened testicles, a shriveled penis, general laxity of the muscular formations, weakness and insufficient contraction, particularly of those muscles which govern ejaculation, incomplete erections, discharge of semen on moderate exercise of the abdominal muscles, or of the bladder in urination, delay in the voidance of the urine, and dribbling thereafter are the symptoms of the more pronounced forms of these descriptions.

"The anatomical substratum for such affections is a lowering of the tension of all muscles coming into play in these cases. The small sphincter muscles placed around the openings of the ejaculatory ducts in the urethra, the muscles governing the act of ejaculation, bulbo- and ischio-cavernosus, the fibres extending from the base of the bladder over the seminal vesicles, the sphincter vesicæ, and the numerous contractile fibers embedded in and around the mucous membrane are those in question. The principle for the modus operandi of the psychrophore is based upon the fact that cold stimulation powerfully elevates the tension of the smooth and striated muscles which are directly encountered by it. The thermal gymnastics of certain muscles elevates in a manner similar to mechanical gymnastics the nutrition and capabilities of the muscle."

The temperature should be from 12° C. to 14° C. (53° F. to 57° F.), but never below 10° C. (50° F.). The length of the seance should be about eight to twelve minutes. When the psychophore is used in the urethra, a grasping of the instrument by the compressor is evidence that there is satisfactory reaction. However empirical this theory may be, it has practical benefits and is worthy of use.

Long before our present understanding of the pathology of posterior urethritis and colliculitis, sounds, instillations, portecaustiques, ointment plungers, etc., were used in the treatment of the "sexual cripple" (Sturgis). Benefit was unwittingly obtained by hastening resorption of the plastic infiltrate and fibrous formation in and around the structures in the deep urethra. Modern urethroscopy and improved technique permit more exact diagnoses, accurate localization of lesions and more satisfactory treatment.

The water dilating urethroscope is necessary for diagnosis, since slight irregularities and small papillary growths on the mucosa lie flat and invisible when opened to the air. Unfortunately, only an approximate idea of the capillary engorgement can be formed because of the liquid and the lenses. Both the Goldschmidt and Buerger instruments have their advantageous fields and both are desirable for minute inspection of the region.

For topical application, the Wossidlo tube must be used. If the operator works carefully and gently there is no objection to preliminary examination with a water-dilating instrument and immediately following with a treatment through the Wossidlo tube.

Selection of the medicament for local application depends upon individual preference. Silver nitrate in solutions of 5 per cent. to 25 per cent. is most popular, yet excellent results are obtainable with saturated solutions of picric acid or varying strengths of chromic acid. Galvanocautery or actual free-hand cautery is rarely necessary.

The field must be free from moisture and free oozing, if present, controlled by swabbing with adrenalin.

Routine cauterization of all diseased posterior urethral is fallacious. Those showing a flat, sclerosed, whitish colliculus with pale mucosa and shallow sulci laterali are harmed by superficial irritations. Their salvation rests upon the possibility of retrograde metamorphosis of the fibrous tissue through the hyperemia subsequent to dilatations. The contrary picture, of a macerated and sodden mucosa with a towering colliculis and almost bullous appearance of the ridges beside the sulci laterali will respond gratefully to these cauterizations.

Cathelin[10] has reported five cases of impotence, one of six years' duration, and seven cases of persistent and frequent nocturnal pollutions cured or relieved by epidural injections. Our results with them have been less happy, but not entirely discouraging.

In addition to all of these corporeal attentions, mental relaxation and diversion are necessary to divert the patient's natural tendency to brood over his imperfection. If hope remains for the sufferer, it is

better to select some trivial abnormality, such as a nodule in the seminal vesicle or prostate, and permit him to think that it is the *fons et origo* of his trouble, and as it improves, so will his sexual debility. The physician should always convey the impression of optimism and ever keep in mind that he is dealing with a natural instinct of tremendous power and importance. In this relation, perhaps more than any other between physician and patient, does the element of personality enter. There is no other ailment in which the perseverance and patience of the physician is more severely taxed than in sexual disorders, nor is there another class of patients more profoundly grateful for their recovery.

Conclusions.—Impotency or sexual disorders are present in 6.5 per cent. of all genitourinary cases.

Sixty-four per cent. of sexual disorders are due to or originate in peripheral nerve irritation emanating from the prostatic urethra or the colliculis seminalis.

Lithemia, oxaluria, and phosphaturia are present in 20 per cent. of these patients and their relief should not be overlooked.

The train of symptoms usually attributed to neurasthenia is real, having a definite cause and requiring definite measures for relief.

The treatment is in great part that of chronic gonorrheal urethritis in which optimism should predominate.

A FEW REMARKS ON THE VALUE OF DOING NOTHING.

By RICHARD P. FRANCIS, M.D.,

MONTCLAIR, N. J.

Why should one want to do nothing? Or, to express it differently, why should it be valuable for anyone to do nothing? Isn't it better that all of us should so something rather than that some of us, be it only a few, should do nothing? If a person does nothing, what right has he to live? Can he justly demand from others the necessaries of life (not to mention the luxuries) as just compensation for his exertions in doing nothing? Ordinarily, it is only work that is paid for—either in money or in some commodity that is considered an equivalent for energy expended. Where, then, is the justice in the demands of the man who does nothing for compensation? Can doing nothing be worth something?

Ah, yes, too often is doing nothing the hardest kind of hard work—for one who has not learned how to do it. When the busy man of affairs, who all his life has enjoyed rugged health and has never given a thought to his hygiene, is obliged, from sickness, advancing years, accident, or other cause, to give due or overdue consideration to all his actions—when he is continually told to "go slow," to "draw in his activities," "not to have so many irons in the fire"—he is at first dazed, then indignant, then despondent, then willing to cooperate. Then, perhaps, after the attempt is once made, he may gradually learn the "gentle art of doing nothing," and pass many years of happy inactivity. But too often the beginnings of learning have been too long delayed, and the old dog cannot learn this new trick any easier or more quickly than any other.

Alas, that he did not start right. That the real value of the "all work and no play" adage was not more often remembered and applied by those who need it most. We too frequently hear of the middle-aged man who, when urged or compelled to change the routine of his business life so that exhausted nature may have a chance to recuperate, says, "But what can I do if I do not work? I don't know anything else to do. I've never learned to play games, I don't like reading, you tell me I must not take violent exercise, and to sit down and do nothing would drive me crazy." His activities have been confined to such a narrow circle all his life that he is unable to adjust himself to new surroundings.

Obviously, the remedy for such a condition, should have been begun long before the condition occurred. In other words, prevention rather than cure is as applicable to the proper care of advancing years, or of broken down health, as it is to any other of the multitudinous maladies that beset mankind. If it could be remembered that the problem "how to grow old gracefully" is one that necessarily comes to all who live the allotted span of life, and if, in preparation for this condition, a broad physical and mental development were insisted on for the youth of the nation, grumblings at the frailties of advancing years would be less frequent, or might disappear. For not only would the bodily energies last much longer, but, what is of equal or even more importance, the ability for finding enjoyment in life with even much restricted capacities would fill with peace and satisfaction the quiet years that follow years of tireless activity.

One important reason why men (and women) are unwilling to withdraw from their occupations, either gradually or suddenly, is the feeling that without their guidance the particular business or pursuit in question will be utterly demoralized, and soon go to rack and ruin. This feeling is, in many cases, more or less unconscious and is not realized until the question is asked, "Why don't you go away or take a vacation?" In nine cases out of ten the answer is that, while the individual may be willing and anxious to go, outside considerations prevent. The man of business cannot trust his affairs to any one else, the professional man feels that no one can adequately represent him in his absence. And the woman in the home! How often has she longed to get away from the routine and the drudgery of housekeeping, even though she feels that no one can manage everything just as she would like it? "Of course I don't mean to say that my ways could

not be improved on. Not at all! But who is there to take my place if I go away?" These people, one and all, have bound themselves with bonds firmer than brass. They have made the mistake of assuming responsibility for everything and not asking nor allowing anyone to share it. They do not know how to let anyone else do their work, nor have they given anyone an opportunity to learn.

In nearly all properly regulated schools the time of the pupils is systematically divided into working time and rest or recreation time. In many households there is the same arrangement for the daily life of the child, but in few households is the time for the older inmates properly apportioned. That a "woman's work is never done" is a well-known fact. That it has always been so has been considered one of the necessary consequences of the curse that fell on Eve. But that it should always continue need not of necessity be taken for granted. New ideas, new theories of the proper way of living, more complete realization of how best to utilize the few years that are allowed us on this earth are gradually teaching every one that, no matter what may be the duties or occupations, a certain amount of rest or diversion is useful; nay, absolutely necessary. That this need for rest has been always one of man's greatest wants does not make a sermon on the subject any the less needed. To give advice is easy—to follow it is often more difficult. Incidentally, that is one reason why physicians are so willing to give counsel to their patients how to live. For few of them follow their own precepts. Not only in matters relating to the use and abuse of alcohol, tobacco, and other drugs are they derelict, but they are markedly careless in taking such care of their health, in living hygienic, though it may be hard-working, lives, that they can suggest to their patients that a good example of right living is demonstrated in the life of the adviser. There is probably no profession or occupation whose disciples work harder, who have more cares and responsibilities than practitioners of medicine. And in probably no profession are the laws of health more grossly violated. This is all the more noticeable because medical men ought, from the very nature of their calling, to be more able than other people to take care that their health is not impaired by indiscretion of living. Medical men are notoriously bad financiers. They are easily led to many injudicious investments, and do not acquire the habit of accumulating a reserve fund. Of their animal strength they are just as prodigal. The proper care of their own lives is as much a mystery to them as the proper care of their income.

Some years ago an "Experience Meeting" was held by a medical society—members volunteered to tell of mistakes, or some of them, they had made during their professional career. Some of the accounts were entertaining, some humorous, all were more or less instructive. Some men told of mistakes in diagnosis, others of mistakes in treatment; some told of mistakes made by eminent consultants that redounded to the credit of the narrator; some of mistakes due to youth and inexperience, others of mistakes due to carelessness or weariness. But the greatest mistake of all, the one with the most far-reaching consequences, the one that more than any other should have appealed to all the men present, was the mistake made by every one of not caring enough for his own health, of sacrificing his own future while trying to make others assured of theirs.

While preaching to patients the need of careful living, of conserving the natural energies, of not becoming victims to the nerve-racking, tissue-wasting habits of to-day—while giving this most excellent counsel—the medical adviser is often obliged, for the sake of the almighty dollar, to do extra work. The young physician forgets that he is as human and vulnerable as are other people, and, before he realizes it, has formed the habit of not caring for himself at all, while he is unremitting in his care of others. And very soon this habit, like all other habits, good or bad, has become so fixed that it seems an impossibility for the tired, overworked doctor to get away from his cares, vexations, and worries for ever so short a time. It is so easy to postpone the day of vacation, so easy to keep on in the same old rut, the eternal round of daily and often nightly duties, that constantly wear away the vitality and rejuvenating powers until the man is old before his time.

This habit continues even through the time when the first successes have been won, when the doctor rides on the wave of popularity (the wave being typified by the high-powered automobile), when the office is thronged with patients, and, it may be, an assistant and an office nurse are needed. Even then the habits of constant work are not broken. If it was impossible to get away in the early days, when the foundation of a flourishing practice was being laid, how much more impossible is it to go when the opportunities for work are so incessant, when there is such a chance for making assured and proper provision for the future. To be sure, there are some signs that cannot be ignored. Signs that the long strain is beginning to tell even on this man's iron frame. It may be there is some shortness of breath, or there are many wakeful nights, or more care is taken to eat simple food, to cut down the smoking and the other carnal pleasures of life. The keen sight is not what it used to be, there are occasional pains and twinges in the joints and muscles. But pshaw! The work can be done, it is done, and in a few years more, just a year or two—oh, well, say in six months—the vacation will be taken. A good, long one, too! And anyhow, there are a few important vital matters that simply can't be left unsettled—a vacation taken before this was done would be worse than useless—there would be no rest. And so the specious pleading goes on again, and another postponement is announced and the treadmill grind is continued until suddenly—some day, comes the crash! Nature, exhausted with the steady strain, finally gives way, and all work—and recreation, too—is temporarily stopped and the extent of the damage calculated.

Poor unfortunate, stricken man! Victim of his own misguided zeal and indiscretion! No doubt he many times has thought, "Well, at any rate, it's better to wear out than rust out," as if he could decide which future was in store for him, could so regulate nature's laws that he'll "die in the harness," have that sudden, satisfactory ending to his life's work that all of us, probably, secretly wish for, rather than the lingering, torturing, "rusting out"—a plague to himself and a trouble and anxiety to others. But our desires do not regulate our destiny. We must accept, with the best grace we can, whatever fate comes to us. And we can no more foretell when or how our lives will end than we can regulate the rain or sunshine.

How foolish it is, then, for a man to think that for him some special fate is in store, a fate which he chooses as most agreeable to himself. If we

poor mortals were only a little less human, if we were not so engrossed in our own desires and ambitions, we might possibly give more heed to our immediate needs, and, while taking care of ourselves, yet not be selfish. But it is, of course, too much to expect that man will cease to abuse or misuse the gifts or talents that have been given him. And probably the last accomplishment to be attained will be the realization that temperance in all things should be observed. "Do all things in moderation" is an old and valued adage. We may practise it in many things, in our eating, drinking, and like bodily pleasures. But how few can realize that, for themselves as for other people, moderation in work is just as essential! How few will take the pains to save their strength, renew the vital forces exhausted by brain work and the expenditure of nerves or physical exertion. There are many men who scarcely know what a holiday is. And there are others who, while taking a so-called holiday, will simply transfer their energy and restlessness to some other field. Instead of working at home, they work in some seashore or mountain resort, and think that by simply having change of air and scene they are resting. They deceive themselves in pretending that they have the substance when they have only the shadow.

It is a noteworthy and surprising fact that, while there is no subject whose importance is more generally recognized than that of the habit of rest, the actual practice of this habit is inversely proportional to the amount of its need. Like most other habits which are encouraged for the purpose of taking care of or improving the health, the people who habitually take the proper amount of rest and relaxation are those whose health is in fairly good condition, while the tired, nervous, overworked class cannot find time or inclination for "stopping." Call the attention of these people to the fact that they are laying up for themselves a period of nervous breakdown, and their answers show that either they think themselves superior to such an outcome, or declare that immediate reformation is impossible, though promises of amendment in the immediate future are freely given.

That the recognition of the need of "letting up" on the overstrained conditions of modern life is very general is amply proved by the immense amount that has been written on this subject. In the medical journals, in the monthly and weekly periodicals, in the daily press, one can find articles dealing with this topic from every standpoint. The skilled neurologist, the learned editor, the earnest clergyman, the zealous exponent of the latest mental or moral "cure," the short story writer, and, finally, the omniscient reporter, all have much to say on the matter, much of which is valuable and some of which is futile. But discussion of the strenuous life and its attendant evils is not confined to those who write. It is scarcely possible to attend an assemblage of people, no matter for what purpose they may be brought together, without hearing some reference made to the all-absorbing question: How Mrs. A. has been sent to a sanatorium on account of a nervous breakdown, or how Mr. B., the well-known stock broker, has had to give up business for a time, or how Dr. C. has been obliged to go to Europe for six months. It is not necessary to cite further illustrations. Every one knows that this "great American disease" (as it is incorrectly called), this continual rushing and striving that is subjecting all sorts and conditions of men to unnecessary strain, is almost as great a threat to the welfare of the nation as the great white plague—or that other scourge of civilization, the social evil.

Scientific investigation has found specific germs that are the cause of many diseases and has also discovered remedies that, by destroying these germs or counteracting their effects, cure the patient of the disease. It is doubtful though if skill will ever discover the identity of the "*diabolus inquietatis*," the demon of unrest, by which so large a proportion of mankind is so grievously infected. No microscope will be powerful enough to see him, no chemical agents will be capable of resolving him into his primitive elements, no staining fluids can be used to isolate him and his attendant satellites, the germs of discontent, of envy, of malice, and all of their kind, in fact a regular Pandora's box ful of miseries that may precede or follow but are always in company with the most abundant germ of all. Not only the most abundant, but the most deadly—for, none of the many ills that flesh is heir to can be successfully combated unless this "diabolus" is put to rout. There is no remedy that is more universally employed than rest; it is the only known panacea, the remedy that will help all diseases, be they medical or surgical, be they diseases of body or of mind, be they of long or short duration, of great or little intensity, they all need, they are all helped by the judicious, liberal use of rest. "A good dose of bed" is a favorite prescription with a successful practitioner, and if to this are added a liberal supply of water, both inside and out, and plenty of fresh air, the essentials for the patient's recovery from any disease under the sun have been secured.

It is the eternal desire to be doing something all the time that is the bane of modern life. People are not contented with what they have accomplished but are discontented because they do not accomplish more. The woman in the home laments because, work as hard as she can, there are some details of housekeeping that must be omitted; the man in the store or office is not satisfied because, though he may be doing a good business, his interests are not extending rapidly enough; even the children are infected with the poisonous microbe of restlessness and overtax themselves in school and at their play as eagerly as do their elders. Vacation and change of scene bring no change to these unfortunates, old or young. The sojourn at the seashore or mountains brings no rest, but furnishes another opportunity for expending more of an already overtaxed energy. The trip to Europe, which might give rest and recreation, becomes an exhausting round of sightseeing, that finally leaves the traveler in worse physical condition than when he started, brain and body alike worn out—but with the satisfaction of having seen a few more cathedrals and picture galleries than his neighbor who "did the tour" last year.

One reason for this discontented restlessness is that many people have not the gift of optimism—or, rather, do not cultivate this gift, which, to a greater or less degree, is surely common to all. If only they would try to make the best, instead of the worst, of everything, to see the good that they have accomplished, and not think so much of their failures, it would be a comparatively easy matter for them to be more satisfied with their daily life. And if they were satisfied with what had been done, the inclination for rest and recreation would be felt, and opportunity would soon be found for accomplishing that which had seemed impossible.

This, then, would seem to be the natural sequence of events: First, the power to do our best, *and to feel sure that we are doing it,* to know what are our limitations and to be content to work up to, but not beyond, them. After this to know that one of the best rewards for honest work is rest—a reward that is as much deserved and as useful as the most eagerly sought for wealth or fame. With these two ideas fixed in his mind the tired worker will surely find plenty of opportunity for "doing nothing"—for forgetting the cares and worries of living and, for a longer or shorter time, giving himself up to the happy existence of being an onlooker at the game of life.

16 Plymouth Street.

HERPES ZOSTER, ACUTE POLIOMYELITIS AND ZINC PHOSPHIDE.

By WILLIAM FRANCIS WAUGH, A.M., M.D.,

CHICAGO, ILL.

PROFESSOR OF THERAPEUTICS, BENNETT MEDICAL COLLEGE, MEDICAL DEPARTMENT, LOYOLA UNIVERSITY.

In 1883 Landouzy suggested that zoster should be ranked with the eruptive fevers and made of it a specific and infectious malady denominated zoster fever. At certain periods many cases of zoster appear, as if epidemic, and some cases seem possibly transmitted by contagion. Trousseau, Kalmann, and Besnier reported cases, and more recently Thibierge, Sicard, Widal, and Jean Minet have added to their number. These have tended to establish relations of undeniable contagion between zoster with eruption and the malady without eruption. In a recent number of *Paris Médical* Cruchet develops this further. Within a month his clinic at the Bordeaux Hôpital des Enfants saw five cases of zoster in patients whose ages varied between 18 months and 12 years. The quick succession of these cases of a malady that is rare in childhood favored the idea of its epidemic character. In the case of the baby a real contagion seemed to have been established. This child was brought to the hospital for an attack of slight bronchitis and occupied the bed next to a girl of four years who had intercostal zoster. Three days later the disease appeared in the younger child. The only treatment mentioned by Cruchet was the application of a powder of talc and bismuth.

Osler described zoster as an acute specific disease of the nervous system with a localization in the ganglia of the posterior roots. Strümpell says: "It is not impossible that many of the apparently 'idiopathic' neuralgias are to be referred to infectious causes, for instance, in intercostal neuralgias associated with an eruption of zoster." Again; "The attacks of zoster often exhibit a certain epidemic and sometimes even an endemic disturbance, so as to suggest an infectious agency. The almost constant swelling of the neighboring lymph glands also favors the theory of the existence of a true inflammatory neuritis." The textbooks are not remarkable for the copiousness or the clearness of the data they afford on the treatment of this painful malady; yet it is one for which we possess a remedy whose efficacy is so certain and uniform that we may make it the starting point for further reasoning. I refer to the phosphide of zinc. In 1890 I had a typical case of zoster in the person of a Jewish youth at Bedford Springs. The family were quartered in an old building whose walls constantly dripped water even in the warmest weather. The hotel lay in a valley, too, much shaded and with too little circulation of air for health. Any infectious germ once present had abundant opportunity to develop and multiply there. The treatment was ineffective until he was given zinc phosphide, in doses of a centigram an hour before each meal. Within two days the attack was under control and recovery was speedy and uninterrupted.

At that time we looked on zoster as the peripheral manifestation of disease affecting the corresponding spinal roots, without a thought of its possible infectious nature. Acting on that theory I sought to extend the use of zinc phosphide to other cutaneous expressions of central nervous disease processes, and with considerable success. Some curious instances of the applicability of this therapeutic doctrine occurred. I looked on the remedy as a possible inciter of nerve activity by the use of which the reparative processes were set in active operation and perhaps a requisite food element supplied. But if zoster is an infection the applications of zinc phosphide must be explained otherwise, and the field of its possible utilization is immensely widened. We begin to recollect that phosphorus has been lauded as a remedy in certain phases of pneumonia, and possibly there is something worth developing in its therapeutics. For instance, zoster is a malady affecting the posterior spinal roots. Is it possible that any remedy can be so narrowly differentiated that it cures an infectious malady affecting especially the posterior spinal roots, and does not similarly act upon another infectious malady mainly affecting the anterior spinal roots? It seems legitimate to give this remedy a trial in acute anterior poliomyelitis.

It is my firm belief that many infections occur through the alimentary canal, more than have been as yet suspected. Apart from this fecal toxemia contributes one element to every febrile malady, which is deleterious to the patient and renders his suffering greater, besides lessening his chances of recovery. For in every fever there is a diminution of digestive secretion, usually constipation, and an enormously increased radiation of water from the body; the absorption of fluids from the bowels is increased during a time when by reason of greater heat and lessened disinfection the bacterial operations are stimulated, and toxins are produced in larger quantity and probably of greater virulence. From these considerations the rule is deduced that in every febrile attack the bowels must be completely emptied and rendered as nearly aseptic as may be possible. This having been done, the affected nervous tissues, abnormally sensitive from the effect of the increased temperature, are not further depressed by being fed with a blood contaminated by fecal matter. The observation of very many cases of various febrile diseases has confirmed me in this belief, and I have been led to compute the part of the attack subtracted by the elimination of this one element as about one-third, or 33 per cent., of the entire symptom-complex. If such an attack is thus deprived of one-third of its gravity, the difference in prognosis is far more than 33 per cent.

This having been done in a case of poliomyelitis, the way seems open for a trial of zinc phosphide as above suggested. The great difficulty is that it is purely experimental. We do not know exactly what the remedy does, or may do, here or even in health. As usual in investigating drugs we come up against the blank wall of our actual ignorance of their exact nature and the influence they exert over the bod-

ily functions. When we ask why any cure is effected we come to the point where experiments should be made and have not been; and the want of data that could be supplied in this way prevents us from comprehending drug action and extending the use of remedies found valuable in one case to others that may present similar features.

Has drug investigation been completed? It has scarcely begun. There is something in the binary elemental combinations not to be found in the unions of salts and oxides. Calcium sulphide is not identical therapeutically with calcium sulphate. The phosphide is not equaled by the phosphate, or the nitrite by the nitrate. We standardize our nuclein by its content of phosphorus; we judge of neurolecithin as a phosphorus pabulum; we have had the hypophosphites urged as remedies for tuberculosis, the glycerophosphates as general vitalizing tonics, the phosphide of copper as an antituberculous agent, and many other therapeutic suggestions based on the presence of phosphorus in the preparation; and all this on the assumption that phosphorus in some form performs valuable feats in the body. But just what does it do and how? Beyond the rather apocryphal repute of phosphorus in impotence, this element is scarcely established in any malady except rickets and osteomalacia, where its power of increasing the deposit of lime salts in the bones is utilized. While it has been recommended in neuralgias and many diseases of the central nervous system, Cushny questions whether it is of any real benefit in these maladies. Wood found phosphorus "apparently act favorably" in the acute nervous exhaustion of typhoid pneumonia. He pronounces it a nutrient tonic to the nervous system and as such applicable in chronic nervous exhaustion, threatening cerebral exhaustion, or myelitic paraplegia from excessive venery, but while mentioning other applications he does not give them his personal endorsement.

Like arsenic, we find plenty of testimony as to the toxic powers of phosphorus. It increases the autolytic activity of the liver, occasions the transfer of fat from the periphery to the internal organs where it is not wanted, and induces jaundice, necrosis, and connective-tissue hyperplasia. Phosphorus itself is not germicidal, since large colonies of microbes flourish on sticks of solid phosphorus; but neither is pure sulphuric acid caustic, and the phosphides may be more active in this direction. The control exerted over herpes zoster by zinc phosphide finds no explanation in any data furnished by the textbooks on therapeutics. That this control is nevertheless real may be proved by any who will put it to the test of actual clinical application. That alone can determine whether this power extends to the disease known as acute anterior poliomyelitis. The experiment is legitimate.

Zinc phosphide should be administered in doses not exceeding a centigram, for an adult and one hour before meals so as to keep it away from the influence of the gastric juice. As a sedative in this group of affections gelseminine far exceeds morphine, especially in that the former tends to favor elimination instead of locking toxins up in the body.

Osteomyelitis in the Course of Measles.—P. Teissier, V. Veau and C. Richet fils describe a case of staphylococcus osteomyelitis of the tibia, complicating measles. Although the bone adjacent to the upper epiphysis was involved, recovery took place with but slight disturbance of the function of the knee-joint.—*Bulletin et Mémoires de la Société des Hôpitaux de Paris.*

TREATMENT OF NEURASTHENIA.*

By F. H. BARNES, M.D.,

STAMFORD, CONN.

MEDICAL SUPERINTENDENT, DR. BARNES' SANITARIUM.

Practising physicians of this day and generation probably come in contact more frequently with this affection than with any other form of nervous disease. Their brains are often taxed to the limit to supply the treatment best adapted to neurasthenic patients. As a class neurasthenics are very amenable to suggestion and are always looking for some one to comfort them in their affliction. Naturally, they turn to all manner of creeds and cults, which makes it doubly hard for the physician, as he not only has to contend with the general phases of the disease but has the added work of getting the patient to forget the advice of all these so-called mind healers, faith-curists, etc. Suggestion has a strong place as a therapeutic measure when controlled by a conservative medical man, and with this class of patients it can be used to advantage. Gain their confidence by listening carefully and willingly to a recitation of the history and cause of the disease from their standpoint. Make a careful physical examination, examine the heart, lungs, liver; ask them if they are constipated or have diarrhea, if they sleep well and eat well; ask them if they have bad dreams; if they have morbid fears and anxiety; go into their family history and find all of the data possible. These patients want plenty of attention and expect it from their medical adviser. Never laugh at them, as they are apt to think that they are a subject of ridicule and imagine you are making fun of them. Remember that they are sick and need your best advice and sympathy, and after you get their confidence you will find that it is much easier to get results in treatment. Many of these patients change physicians because busy practitioners refuse to listen to a detailed account of their symptoms, telling them that they are well and only imagine they are ill; to get busy with their work and they will be all right. Nothing hurts a neurasthenic more than to be told that he is not ill, as he wants sympathy and will get it some way, even if he has to go from doctor to doctor to do so. I emphasize this point, as it is the testimony of many of these patients that they have tried numerous physicians to get a sympathetic hearing, but have failed to do so. Ofttimes serious organic disease exists under the mask of neurasthenia, and can only be differentiated by your diagnosis. Many men under high pressure of the present-day business methods develop this disease but are unable to leave their work long enough to change their environment or go to any of the various sanatoria. Such cases must be treated at home, and if their family physicians make light of their trouble they will soon seek treatment elsewhere. It is far better that these patients should stop work. Most of them need rest in some form or other, because their condition is the result of worry and overwork, and they should have every chance within reason to recover their normal physical condition. This can best be done by a reasonable amount of rest. Neuromuscular fatigue and general irritability interferes with the daily work; sleep is not restful; headache, backache, constipation, and gastrointestinal disorders accompany this disease and have their influence in making the patient depressed and irritable. They require the stimulation of a personality strong-

*Read before the Williamsburg (N. Y.) Hospital Staff Association February 6, 1911.

er than their own to brace them up and help throw off morbidity. Listen to their troubles; instruct them that they are not going to be insane, that their disease never ends in a psychosis; that their periods of depression and excitement will not lead to any serious result; also inform them that their trouble is not organic, but functional, and that they are not going to die of heart trouble or any intercurrent disease. Tell them that you have had many such cases, and that they all recovered after proper treatment. Suggest that they will soon have good sleep; that their digestion will improve; that they must not worry, and if possible persuade them to take a short vacation, accompanied by a cheerful companion or in pleasant and healthful surroundings. This alone in mild cases will be almost curative. Have patients take a short rest of an hour once or twice a day; the rest cure in a modified form can be used; keeping the patient in bed one-half the day, the other half up and out of doors, works nicely in some cases. Many will not remain in bed, and grow worse under such treatment, especially the depressed cases. Long railroad and steamship journeys as a rule are to be condemned; the excitement of such travel does not benefit the patient, and they return ofttimes in worse condition than before they started. Most neurasthenics are troubled with constipation, some having bowel movement two or three days apart. Prescribe the necessary cathartics, such as cascara, occasional doses of calomel, and the daily use of sodium salts. If the patient is anemic and has lost weight rapidly, iron and arsenic, together with some of the tissue builders, are indicated. Persons who are well nourished with plethora, inclined to obesity, should not have stimulating tonics. Strychnine, phosphorus, and arsenic are not indicated in the majority of cases of this disease. The bromides are far better for routine treatment; of these strontium bromide acts best, as it is not so irritating to the stomach. Digestive ferments can be used to good advantage, as they often help to relieve the toxic condition which invariably accompanies neurasthenia. A prescription often used in the neurological clinic of the New York Post Graduate Hospital is sodium bromide, 1 ounce; charcoal, 2 drams; dilute hydrochloric acid, 4 drams; fluid extract of cascara, 2 drams; compound elixir of pepsin, sufficient to make 4 ounces. Of this mixture the patient is given one teaspoonful three times a day, after meals.

Hydrotherapy is a very useful measure, and can be administered in the form of hot baths before retiring to relieve insomnia. Some of these patients do not like cold baths, but most all of them will tolerate a cold douche to the spine after the hot bath, which douche has a stimulating effect. Personally I find good results follow a warm shower, gradually cooling the water to a point of toleration by the patient, followed by a thorough rubbing with a rough towel. Pressure treatments from the hose, which can be had only in some of the bath establishments or cures, are very effective, and induce quick reaction. Salt rubs given by trained attendants are very grateful to the patient, and aid materially in diverting the attention during the treatment. All measures which cause the patient to forget his worry help. During the heated term sea bathing not only supplies a therapeutic adjunct, but is also helpful in giving the patient proper exercise. Stimulants of all kinds should be forbidden; if permitted, they must be taken in moderation. I have never found small amounts of coffee or tea injurious to these patients. Smoking is not harmful unless indulged in to excess, but morphine or opium in any form should not be given, as these patients easily form the drug habit. Milk is one of the best foods, especially in bed cases who are taking the rest cure. A combination of milk and eggs is generally well tolerated, as is a light nourishing diet leaving out those food substances which contain an excess of the starches and sugars; no food which causes the formation of toxins should be permitted; especially beware of overfeeding. Have the patient drink plenty of good spring water, four to six glasses each day. Massage is very beneficial to most cases, but should not be given forcefully in the anemic type. Static electricity before the patient retires will cause him to sleep better and should be given simply as a breeze current from the head spray. Where the patient complains of severe bodily pain a high-frequency current applied to the affected part causes temporary relief. (This may be entirely mental.) In extreme insomnia veronal and trional can be used in 5 to 10 grain doses. The bromides in small doses are often sufficient.

Hammond recommends proper exercise. He does not believe in the rest cure for most of these cases, stating that they improve more rapidly in the open air, taking a certain amount of exercise. This is a factor we must consider, as it not only gives the patient added muscular strength but helps to make the plan of something to do during the working hours much simpler. Any of the ordinary forms of exercise can be used, but it is not wise to be too strenuous. The neuromuscular fatigue is a natural check on the patient, and it is better to graduate the exercise to the ability of the individual rather than to treat all alike. Walking in the open air, in my estimation, is fine exercise, and one of the best for neurasthenics. Have patients walk one mile the first day, and if they cannot walk that distance let them walk half a mile; increase from day to day, and in a surprisingly short time they will be able to walk from ten to twelve miles in twenty-four hours with very little fatigue. Another method is to have the patient walk five minutes one way and return, and increase five minutes every day; above all insist that they walk with head and shoulders erect, and at a good, rapid gait, as they are apt to slouch along in a bent-over manner unless told to do otherwise. Bicycling, tennis, golf, swimming, and the lighter gymnastics all have their place when properly employed. Much has been said of occupation during the course of this disease. Personally I find it very difficult to get the neurasthenic to consent to do work of any kind, as they are so self-centered that it is difficult to get them interested in anything which calls for thought or energy on their part.

Sanatoria are very helpful in the treatment of neurasthenia, as the patient is under constant medical supervision and in care of nurses or attendants trained to carry out a regulated daily life best adapted to the individual. Patients who have morbid fears feel that they are protected from harm; others feel that they have moral support in combating their worries and some one to whom they can reveal their thoughts, so that sympathy will be given them in their affliction. In a short time they have confidence in those who care for them, which aids materially in persuading them to do what is necessary on their part to carry out the plan of treatment mapped out for their daily routine.

Dercum in the treatment of neurasthenia empha-

sizes the following: "Another element in the treatment is, as Mitchell and Playfair have both pointed out, the isolation of the patient. Not only is the patient the victim of a neurasthenia, but in very many instances also of hysteria. Neurasthenia and hysteria are, as we have seen, often inextricably intertwined. Under these circumstances isolation, the withdrawal of the patient from the influence of relatives and friends, is of the utmost importance. How deleterious home surroundings are under these circumstances need not be dwelt upon. In cases of nervous prostration which are sufficiently pronounced to require rest in bed isolation is imperative, and it should be absolute. No exceptions should be made in favor of any relative, nor should any communication ever reach the sick room, except through the mouth of the doctor, and then even should be most guarded and most general in character."

The writer's experience accords with that of Drs. Mitchell and Playfair that even slight infringements upon this rule are sometimes followed by the most unfavorable results. We find, then, that our resources for combating profound neurasthenia comprise artificial exercise, namely, massage and electricity; a special diet, and isolation.

PNEUMONIA.

By C. S. WEBB, Ph.B., M.D.,

BOWLING GREEN, VIRGINIA,

FORMERLY PROFESSOR OF THE PRACTICE OF MEDICINE IN THE SOUTHERN MEDICAL COLLEGE; MEMBER OF THE VIRGINIA MEDICAL SOCIETY, TRI-STATE MEDICAL ASSOCIATION, ETC.

I HAVE recently had three cases of pneumonia which seem worthy of notice, with the thoughts that have come to me during the treatment. The first case, a young man about twenty years old, was taken with slight cough, a temperature of 104°, which fell to 103° and 102°, and gradually down to normal, when the upper lobe of the right lung was hepatized. Respirations were now about 30 and the pulse was about 110. About the time this case was beginning to sit up and ready to be dismissed from treatment, about two weeks from the start, his roommate, who had also been his nurse, was taken with cough, a temperature not above 102½°, and no other symptoms except headache. Four days later his temperature went up to 103° and his respirations to 50. His pulse, however, was only 90, but full and strong. Almost all of his right lung was hepatized, and a portion of the left. This was Monday night, and he had been taken ill the preceding Thursday. The next day his pulse was 120 and continued so, with respirations 50 to 55, until Friday night—that is, 72 hours from the onset of his rapid breathing. During all this time his cough was persistent and expectoration copious, greenish yellow, and bloody. He is now about well (the nineteenth day).

The third case was a youth of seventeen years, whose temperature never went above 102.5°, who had no cough, and whose respiration was not over 40, and then only for a few hours; the upper lobe of the left lung was hepatized, pulse satisfactory, and the whole case from the beginning to dismissal from treatment took just one week.

With these cases before us, I desire to note a few facts about pneumonia. What becomes of the statement in our textbooks that the temperature is always high? Even the best of our profession have been in the habit of making the temperature a diagnostic point, and if it is not high they decide at once that the case is not pneumonia. I once had a case in which the diagnosis was doubtful, but the patient was desperately sick, and when a professional brother, from the city, was called in, he at once decided that "pneumonia would have shot his temperature away up yonder." I am speaking now of the first stage, when the auscultation signs are often obscure and reveal nothing definite. The presence or absence of cough, too, is often embarrassing in making up a diagnois. In the above three cases one notes in the first, slight cough; in the second, very troublesome cough, with copious bloody expectoration, and in the third, no cough at all. It must be noted, also, that the breathing, its difficulty or frequency, is not always in keeping with the extent of lung involved, but is often entirely out of proportion. This is due to the oppression of the poison on the nerve centers and especially on the heart. Hence, the heart is weaker and at the same time has more work to do, the right side of the heart being especially oppressed from the extra influx of venous blood.

It has often been said, and I have said it, too, that we do not know any more about the treatment of pneumonia now than we did twenty years ago. We say this sometimes in an offhand way, when we get discouraged at the slowness of our progress in mastering this dreadful disease, but the statement is not exactly true. We know now, for instance, that it is altogether wrong to attempt to bring down the temperature with anything that might in the slightest degree weaken the patient's reserve force. It is a thousand times better to let the temperature alone than to do any such thing. In the cases cited above I gave four grains of cinchonidine sulphate every four hours until the first stage was over. This is a fairly good antipyretic, and is a tonic to the system. I also gave creosote carbonate, twelve drops every two hours, as recommended by Charles F. Stokes, U. S. N., some ten or twelve years ago, and used by me in these cases ever since. We know now, also, that we must look out for the heart, for reasons already stated above. Here is where the chief danger lies. Strychnia and alcohol are both useful. I heard a physician from South Carolina say, in speaking on this point before our Tri-State Convention, that his chief reliance was sparteine. I have been greatly disappointed by it, and do not use it now. In the cases cited above I used only strychnine nitrate in the first and third, but in the second, when the respirations were 50 per minute, the countenance anxious, the feet cold, the pulse 120, and inclined to be flabby, I used adrenalin chloride, 20 minims every 4 hours, and strychnia, 1/30 grain, every 4 hours; these drugs were given alternately, day and night. I do not hesitate to say that adrenalin chloride is the best of all remedies known to me for supporting a weak heart and tiding over a crisis. I have seen it act almost like magic in cases where cyanosis had already set in. We know now, also, the value of fresh air in pneumonia. In the case just cited I had the door opened and the window at the head of the bed wide open, all the time, day and night, so that the fresh air from outside came right on to his face when the thermometer was 32°. He was, of course, well covered, just comfortably so, no, or very little, fire in his room. I believe I am justified in saying that we do know more about the treatment of pneumonia, and that the mortality under the treatment briefly outlined above would be

smaller. I am now thinking of at least two fatal cases that might have been saved if they could have been treated on this plan. Of course, the importance of nutrition must not be overlooked, but nutrition, stimulation, and fresh air, must be the watchwords.

The practitioner must not lose sight of the fact that no two cases can be treated exactly alike. The general principles of treatment may be the same, but the modifications call for good judgment and sound commonsense. The main object is to keep the patient alive. Pneumonia is a self-limited disease with three stages, and if we can keep the patient alive long enough he will get well. It is a battle between the disease and the patient's strength, for a limited time, so that while we, as professional men, are fighting the disease, let us hold on to the patient.

A CASE OF TRANSPOSITION OF THE HEART.

By NATHANIEL P. BROOKS, M.D.,
CONQUISTA, COAH., MEXICO.

The following is a report of a case that seems to be one of a well-defined transposition of the heart.

My attention was called to the abnormal location of the heart while I was making an examination for suspected tuberculosis. The patient was a young girl. Although I was firmly convinced that the heart lay to the right, nevertheless, since the señorita's mother was not present the examination was not very satisfactory. The present findings are the result of a more thorough examination. It was only after I had hinted at a complaint to the judge and a fine that I obtained permission to examine the girl. This shows how difficult it is to get the people here to conform to our ways even when we are working for their good.

The family history is not very complete. The mother does not know her exact age, but places this in the neighborhood of 40. The father is 37. Both are in good health and give no signs or symptoms of a luetic or tuberculous taint. Both are natives of the State of Nuevo Leon, coming from Villa de Garza. The parents with their family moved to the coalfields several years ago, having lived in several of the mining camps. Personal history: Señorita Amelia Garza, now in her thirteenth year, complains of no symptoms at present. There is a history of several illnesses, but the nature of them is mere conjecture and do not in any way have a bearing on the present findings. Menstruation has not as yet been established; this is the only thing that the mother thought out of the ordinary, as in this climate menstruation begins, as a rule, on or before the twelfth year in girls belonging to the same class as the patient.

Physical examination: Girl of good development, 5 feet in height, about 40 kilograms in weight; color good, hair rather scant and short; mucous membranes show a slight anemia. The chest is of good shape, well developed, expansion good; a slight lateral curvature of the spine is not noticeable with the clothing on. The apex beat is visible in the fifth interspace, 2.5 inches to the right of the midsternal line, 5 inches below the ensiform cartilage in the mammary line, which in this case is identical with the midclavicular. There is an epigastric pulsation visible but not abnormal. The apex beat is easily palpable. I first discovered it palpating through the clothing. Palpation locates the beat as given above. There are no other pulsations or tumors discovered on palpation. Percussion outlines an area of dullness and flatness on the right side corresponding closely to the findings on the left in the ordinary person, while the ordinary area of cardiac dullness on the left gives a pure lung resonance which extends well down toward the free margin of the ribs. Otherwise the percussion of the chest is as in the ordinary individual, which leads me to believe that the liver and other organs are not transposed. Auscultation confirms the findings of inspection, palpation, and percussion. The first sound is heard with maximum intensity in the fifth interspace 2.5 inches to the right of the midsternal line on the mammary line; this is of good quality and normal in all respects. The second sound is clear-cut and well-marked, apparently the more pronounced in the third interspace at the right border of the sternum. It can likewise be heard very distinctly in the second interspace. The difference in intensity is very slight. There is also a distinct second sound heard in the second interspace at the left border of the sternum; there is very little difference in the intensity of the sounds at the three points mentioned. In the back the first sounds are plainly heard on the right side, but I could not detect any heart sounds on the left. The gurgle after a swallow of water seems to be heard best to the left of the twelfth dorsal vertebra. The only other physician to see the girl was Dr. Thrasher of the Palau mines, who confirmed my observations.

Presence of Gonococci in the Blood in Gonorrhea.—Filipo Lofaro shows that researches have been made to prove that gonorrheal arthritis is directly caused by the presence of the gonococcus in the joints. It also has been proven that the usual complications of gonorrhea are but new localizations of the germs. The author made a study of the presence of the germs in the circulating blood in 67 cases of acute and chronic urethritis. He demonstrated the presence of the germs in the blood in 58 per cent. of these cases. They were not present in the acute cases, but in the chronic cases, in which there was greater virulence of the germs or deeper lesions, the gonococcus was present. The author does not know how these germs penetrate from the urethra into the blood, but supposes that in more severe cases they crowd the lymphatics, and in this way get into the blood.—*Il Policlinico.*

Pelvic Metastases from Cancers of the Upper Abdominal Organs.—Ch. Lenormant says that in many cases of cancer of the organs of the upper abdomen, such as stomach and pancreas, after the removal of the cancer, and after the good condition of the patient has existed for some months or years, we find appearing bilateral ovarian cancers, growing rapidly and very malignant in type. These annexial tumors may exist alone or be accompanied by an extended generalization of the primary cancer. The point of interest is the mode of invasion of the ovary, whether the infection is by way of the blood or the lymphatics, or by a direct ovarian graft from cells that have fallen into the peritoneal cavity at the time of the operation. The hypothesis of an affection by the blood would hardly explain the localization which selects the ovary for its attack. The lymphatic theory is defended by Schmorl, Glockner, and Pfannenstiel. The most probable supposition is that of a direct grafting by cells that fall into the peritoneal cavity. Kraus and Polano have shown experimentally that solid particles, such as India ink, injected into the peritoneal cavity, penetrate the ovary through the intact epithelial covering. The primary tumor may be entirely latent in some cases, only the ovarian growth being in evidence. In still other cases of gastric cancer, ovaries that appear perfectly normal may be already involved in the cancerous growth. It is found that cancers of the posterior cul-de-sac are even more frequent than those of the ovaries. The rectum is frequently involved in this way. From these facts one may make the practical deduction that in cases of cancer, vaginal and rectal examinations, and examination of the stomach or pancreas should be made before operation is decided upon. In every operation on the adnexa for cancer we must also examine the organs of the upper abdomen.—*La Presse Médicale.*

MEDICAL RECORD.

A Weekly Journal of Medicine and Surgery.

THOMAS L. STEDMAN, A.M., M.D., EDITOR.

New York, May 27, 1911.

THE NEXT PRESIDENT OF THE AMERICAN MEDICAL ASSOCIATION.

DURING the past fifteen years ten surgeons, not counting General Sternberg and Colonel Gorgas of the Army, have been honored by election to the presidency of the American Medical Association, while only two practising physicians, not counting Dr. Welsh, a pathologist, have enjoyed this distinction. The physicians may therefore justly claim the right to be recognized by the elevation of one of their number to that honor at the forthcoming meeting in Los Angeles. The nomination and election to this high office are, it is true, in the hands of the Delegates, the general body having no deciding voice in the matter, yet the members have the privilege of indicating their preference and suggesting the names of those whom they would wish to see thus honored by the Association.

Exercising this right of proposal, the MEDICAL RECORD would suggest a physician of New York, one who has ever by his teaching and his conspicuous example reflected credit upon the profession of medicine in this country and in the world, one who has occupied the highest positions of honor and trust in the bestowal of his colleagues in this State and city, who has several times been called upon to represent his adopted country in the International Medical Congresses, and who is esteemed by the laity also as one of the most illustrious of American physicians. We need hardly add that the name of this physician is Abraham Jacobi.

DISEASES AND WEEDS.

MEDICINE is a subdivision of biology. Only by a realization of this fact can one rationally interpret the broad and fundamental problems of disease. The Indiana Academy of Science, in the organization of a committee on weeds and diseases, shows a correct appreciation of the importance of attacking disease from the vantage ground of universal laws applicable to both plants and animals. As chairman of this committee, Robert Hessler contributes to the *Survey*, April 1, 1911, a paper in which this subject is presented in a manner interesting to both medical and lay readers.

It is pointed out that at one time all the common weeds, pests, parasites, and infectious diseases were restricted to certain localities, whence they have spread until they have become cosmopolitan. Most of the worst weeds are foreigners that have come from all parts of the world, especially from Europe, where all weeds have been fought from time immemorial and where certain ones have acquired extraordinary powers of resistance. The introduction of influenza into this country is analogous to that of any of the multitude of weeds that have gained a foothold in the virgin soil of this continent. The problem of eradicating disease is therefore one of human gardening. But, like all other analogies, this one, if carried too far, leads to absurd conclusions. Hessler speaks of human weeds in the same sense as he refers to parasitic plants. He asks: "Why is it that such an undue amount of attention is given to 'human weeds'? Asylums are erected for them where they have the best of attention, where they live on to old age. Why must a man wait until he becomes insane, or a pauper, or a criminal, before being housed under sanitary surroundings?" These questions cannot be answered merely because they betray a woeful ambiguity of terms. The insane, the paupers, and the criminals are all put in the same category and are regarded as human weeds. The reasoning is superficial which cannot discriminate between the insane who are the victims of an adverse environment, the human derelicts in the relentless storms of modern civilization, and those whose minds are shattered by a life of indulgence and perversity. Is the pauper to be regarded as a social parasite if perchance he is the unfortunate victim of an accident through no fault of his own? The criminal classes may with greater propriety be regarded as the parasites of society; nevertheless, modern science regards some criminals at least in the same light as the insane. The author falls into the greater error of characterizing the individual who is infected with some microbic disease as a "human weed," apparently by some mental prestidigitation transferring this conception from the infecting germ to the infected person in whom the former finds a soil suitable for its growth and multiplication.

In spite of this confusion of terms, however, the horticultural analogy is a suggestive one, for it emphasizes the importance of attention to soil and surroundings, of constant care in the rearing of human plants, and the control of abnormal tendencies. This attitude is particularly important in teaching the young that in proportion as attention is given to plants and to their protection from noxious influences they are enabled to thrive.

There is one other line of thought in which the temptation to delineate glittering contrasts leads the author into the mists of speculation. Hessler notes that although specific epidemic diseases are decreasing common ill health is increasing. It is impossible to agree with this statement. The general average of health is better to-day than it has ever been, as attested by actuarial estimates as to the increased expectation of life. Neither can one subscribe to the statement that the number and size of a city's hospitals are an index of the amount of

sickness, particularly of a preventable kind. The increase in the number, size, and equipment of hospitals is to be regarded rather as an indication that the conscience of humanity is growing more keenly alive to the suffering of the unfortunate; and that the development of modern scientific medicine compels an increase in the facilities for caring for the sick. Hessler treads on firmer ground when he states that the plant breeder is constantly seeking to eliminate the unfit, but that man cannot proceed on the same plan regarding his own kind.

ALCOHOL AND INSANITY.

There has been recently in Great Britain a discussion, not devoid of acrimony, between the hard and fast upholders of rigid temperance and those who go so far as to say that the evil effects of alcohol may have been in some instances exaggerated. The debate, which chiefly took the form of correspondence in the *British Medical Journal*, was initiated by some statistics gathered by Karl Pearson and Miss Elderton regarding the effects of alcohol in parents upon their progeny. Pearson stated that the investigation undertaken by him and his coadjutor seemed to show that parents who drank had children as healthy mentally and physically as parents who abstained from alcohol altogether. This pronouncement raised a storm and the total abstinence followers, headed by Sir Victor Horsley, disputed the figures brought forward by Pearson. In the course of the discussion F. W. Mott, an alienist of repute in Great Britain, advanced the statement that there was generally definite evidence of prolonged abuse of alcohol in the notes of the hospital cases of cirrhosis; but in reference to asylum cases, there was found the most meager information regarding relatively few cases.

In the *Medical Press and Circular*, April 19, this author published an address on alcohol and insanity in which he says his recent inquiry into the matter supports his former contention that heredity is the predominant factor in all cases of admission to asylums that are not due to organic disease. He, however, freely admits that the abuse of alcohol aggravates the effects of syphilitic infection, the most potent cause of general paralysis of the insane, and is an important coefficient in accelerating and even determining the onset of all organic nervous diseases, just as it does functional neuroses and phychoses in individuals of a neurotic or insane temperament. In short, cause and effect are often confounded in these cases, and, it is as often that a person drinks for the reason that he is not normal as that the drink itself causes insanity. Of course, drink will aggravate either organic or functional nervous diseases, but it is doubted by many if indulgence in alcoholic beverages *per se* will cause insanity. Mott thinks, with regard to the effects of alcoholism upon the offspring in relation to insanity, that cause and effect are here also not infrequently confounded.

From his asylum experience he has learned that in a study of the pedigree of the insane there is frequently a back history of mental aberration sometimes in weak ancestors and sometimes in more remote forebears. Therefore he has come to the conclusion that many of the statements and statistics made in respect of alcohol being the direct cause of insanity appearing in a stock must be accepted with reservation until more precise data have been obtained.

Finally, Mott does not believe that a desire for alcohol is transmitted from parent to offspring in the form of like begetting like, but a tendency to like; that is to say, that an inherited weak willpower and lack of moral sense may be transmitted, whereby the individual is more susceptible to temptation and imitation, and in this way environment plays an all-important part.

SOME OF THE CONSEQUENCES OF OVEREATING.

In the *Southern California Practitioner*, April, 1911, is an instructive and valuable article on overeating and its consequences, translated by Dr. Boardman Reed from a paper by M. Marcel Labbé. Labbé is of the opinion that there is a very large number of persons who suffer from eating to excess. He points out that a great many people hold the view that so long as the diet is nourishing and digestible they may, with impunity, eat very large quantities of such food. There are, however, dyspepsias caused simply by superabundance of nourishment. Therefore, Labbé thinks that in the prescription of a diet the physician should not be content with indicating the quality but should also prescribe the quantity of food permitted.

He further draws attention to the fact, which should be especially taken to heart by the urban inhabitants of the country, that the digestive disorders so frequent in people living in restaurants and hotels are indeed due more to the excessive quantity than to the bad quality of the food. "Nothing," he says, "is more dangerous than the table d'hôte with a multitude of viands." The writer then gives in detail the various injurious results to health brought about by overeating and Reed adds to the long list of complaints a very serious one which the French professor does not mention, namely, arteriosclerosis, which most recent writers attribute to a great extent to overindulgence in the pleasures of the table. Labbé recommends the usual methods for diagnosing the dyspepsias of superalimentation, namely, an analysis of the urine properly interpreted, and Reed suggests that when the patient is over weight that alone is proof that a surplus of food has long been habitually taken. In the case of any person who is not over weight the doubt can be settled by reducing gradually the amount of nourishment consumed and noting meanwhile the effect on the body weight. If with less food the weight remains the same, or even increases, as it often does through an improvement in the digestion, the amount eaten before was excessive and symptoms would certainly have developed later.

There is little doubt that overindulgence in eating is very frequent in this country and especially

in the cities. There is probably no country of the world in which so large a number of different foods are placed on the table. Furthermore, this is essentially a country in which people eat in restaurants and hotels, where there is a very wide choice of viands. Especially are the breakfasts consumed by the average American often immense in quantity and not always of the most digestible ingredients. In short, it is obvious that many are digging their graves with their teeth and it would be well for them if they paid heed to the advice of Labbé and Reed. Moderation in eating is almost as important to health as moderation in drinking alcoholic and other stimulating beverages.

The Diminishing Birth Rate Versus Overpopulation.

There are two sides to every question. Consequently the diminishing birth rate, or what Colonel Roosevelt so glibly termed race suicide, may have arguments in its favor. In fact, that it has features which must not be altogether condemned is evident. In the *Popular Science Monthly* Scott Nearing, instructor in economics in the University of Pennsylvania, briefly states the case for the limitation of families. At the beginning of the article he freely allows that there is "a conscious restriction of the birth-rate on the part of the vast majority of American families," but he contends that those who use methods to restrict the number of children should not only not be subjected to severe criticism and ridicule, but should be regarded as race saviors. The main argument adduced by Nearing in support of these opinions is that a continuance of the rate of increase which prevailed in the early nineteenth century would have resulted in the western world in an overpopulation with which it would have been difficult to cope. Further than this, he points out that the death rate has been so greatly reduced that unless measures had been taken to limit the output of children the civilized world would be filled to overflowing with members of the human race. Of course, Nearing argues as an economist. Owing to the high cost of living and the desire to live well and to keep up appearances, the well-to-do parents of all classes, to a great extent have taken steps to have few children, and thus the population has been kept within reasonable bounds. There is one feature of the situation, however, which Nearing has neglected to notice, and that is that the increase of population continues without slackening among the least desirable portion of the community, and the result may be that the respectable, intelligent, and law-abiding section will be swamped by the idle, ignorant, and lawless. In Europe, and especially in Great Britain, this aspect of the question is exciting much alarm. In America, and in this country in particular, the uneducated and in some respects undesirable foreigner generally has a large family and may in the course of time, by sheer force of numbers, gain control and oust the comparatively few of native stock. Although quality counts, so also does quantity, and the families possessing quality should at least be kept to such a numerical point that there should be no fear of the more ignorant portion of the population occupying the seats of power. Nearing says that the family of eight among the desirable inhabitants has by artificial means been reduced to two, and is inclined to regard it is a matter of congratulation. The question appears to be whether a family of this size is large enough to preserve the necessary equilibrium.

Huntington's Chorea.

One of the few eponymic diseases described by an American, which is known by its discoverer's name throughout the world, is Huntington's chorea. There is something remarkable about this fact. Dr. Huntington was a rural practitioner and had no affiliation with colleges. Furthermore it would have been very easy for foreign writers to style the disease hereditary, or family, or chronic chorea. But by a condescension of fate Huntington received his full dues in the matter. He took advantage of an opportunity, which others evidently failed to do; but many who have likewise improved such opportunities failed to obtain recognition even from their native contemporaries. At a recent meeting of the Breslau Psychiatric-Neurological Society, reported in the *Berliner klinische Wochenschrift* for April 17, Freund read a paper on this subject which was well discussed. A case was reported in which two brothers suffered. Heredity could be shown in three generations, both as chorea and as insanity. A number of individuals making up the generations were normal. One brother was first attacked at 6 years, the other at 12. At present their ages are 44 and 50 respectively. The disease began insidiously and developed very slowly. There was no history of common chorea in childhood, nor of alcoholic abuse, nor of any other possible contributory factor. The younger brother stuttered as a child. Strange to relate the older brother was naturally very apt in muscular movements and had been noted for his skill in dancing. Despite the march of the disease he had been able to dance well until a few years before consultation. Nothing could better indicate the crushing impact of a late inherited taint. Both brothers had been skilled mechanics. Neither had been bright in school work. The younger brother suffered from psychic depression with a tendency to apathy. The older was troubled with insomnia and was very excitable. The choreic and associated movements were those described in systematic writings.

Cerebrospinal Meningitis Among Immigrants.

The latest accounts indicate that the danger of an epidemic of cerebrospinal meningitis in this country, while not very great, still remains practically the same as it has for several months past. The disease is still prevalent in Greece and continues epidemic in the consular district of Patras, which is the principal port of departure for ships carrying Greek immigrants to the United States. During the two weeks ended April 22, there were 21 deaths reported from Athens and Piræus as due to this cause. In this connection it is worthy of note that the work of the Health Officer of the port of New York is materially aided by the fact that after a vessel has been passed at quarantine its steerage passengers have still to undergo detention and a second examination by the immigration physicians at Ellis Island. That the delay thus caused in the final landing of the passenger often affords time for the development of other cases of quarantinable disease is shown by the fact that twenty-eight cases of cerebrospinal meningitis have been received in the Ellis Island hospital since October 28, 1910.

Osteopsathyrosis.

This peculiar bone affection, which has been found to be in association with defect of the thyroid, may appear as a familial affection, as shown by a case reported by Hartmann before the Leipzig Medical Society on February 21 last (*Berliner klinische Wochenschrift*, April 10). A brother and sister, children of healthy parents and seen at the ages of 18 and 20 respectively, gave a history of having suffered from this affection since infancy. The general contour of the skeleton, and the excess of fatty tissue, were not wholly unlike those of the cretin, but in these patients the intelligence was normal and there were no anomalies other than the defect of the thyroid. Fractures of the bones of the lower extremities had occurred over and over, with cumulation at puberty. The *x*-rays showed a high degree of deformity and atrophy of the bones. The management is chiefly surgical, although phosphorus and thyroid extract are often exhibited.

News of the Week.

Registration of Births and Deaths.—In an opinion rendered to State Commissioner of Health Porter, Attorney-General Carmody of New York defines the powers and duties of local boards of health and of the State Department of Health in enforcing the laws requiring prompt and complete reports of all births to be filed with the department each month. The law requires that physicians report births within thirty-six hours, and deaths within twenty-four hours after they occur, to the local board of health on a prescribed form, and gives the State Commissioner of Health authority to take charge of the local registration in any municipality where defects are known to exist in such registration, until satisfied that the local board of health will make the record and registry complete according to law. After commenting on the importance of complete vital statistics in any community, the Attorney-General concludes that where a local board of health neglects or refuses to make and enforce the ordinances as provided by the public health law the State Department may mandamus such board, or after due notice may take control of the registration in any municipality, "and also that persons violating lawful health ordinances may be prosecuted under section 1740 of the Penal Code, and where a physician is found guilty of violating the public health law, or section 1740 of the Penal Code, he may be proceeded against under the provisions contained in section 170 of the public health law for the annulment of his registration and the revocation of his licence to practise medicine in New York State."

City Death Rate.—For the week ending May 13, 1911, there were in New York City 1,588 deaths as compared with 1,468 deaths for the corresponding week last year, the death rate being increased from 16.14 to 16.62 per thousand. Among children under five years of age there were 475 deaths, an increase over last year of 38. Two hundred and twelve deaths were due to pneumonia, and 210 to pulmonary tuberculosis. For the first three months of the year the death rate was below that for 1910, and considerably below the average for the last three years, being 17 per thousand, as against 17.45 for the same period in 1910, and 18.33 average for the first three months of the previous five years. The decrease was particularly noticeable in the infant mortality, and in the deaths from tuberculosis, pneumonia, and Bright's disease. There was increase in deaths among old people and in deaths from heart disease.

New Hospital.—Through a gift of $100,000 from Mrs. Peter F. Collier, in memory of her husband, Red Bank, N. J., will shortly have a new, non-sectarian hospital. Work on the building has been begun and it is expected that it will be ready for occupancy in about six months. Dr. Peter P. Rafferty of Red Bank has been appointed chief of staff of the hospital.

The Brooklyn Hospital.—Plans are being prepared for the entire rebuilding of the Brooklyn Hospital on DeKalb avenue and Raymond street, Brooklyn, N. Y., at a cost of about $1,000,000. Twelve new buildings will be erected as funds become available. The hospital has already received a gift of $100,000 for the construction of a dispensary as a memorial to the late Mrs. William H. Harriman.

Yellow Fever in Colombia.—An epidemic of yellow fever is reported from Bucaramanga, capital of the Department of Santander, Colombia, which has a population of 15,000, sixty cases having developed within a week.

Report on Matteawan.—The report of the commissioners designated some time ago by Governor Dix to investigate the management of State prisons and reformatories with special reference to affairs at Matteawan was made public on May 14. Because of the numerous allegations that sane persons are confined at Matteawan, the investigators engaged the services of several experts to inquire into the character and discipline of the hospital and into the mental condition of the inmates. As a result of their findings, the commissioners report that no sane persons are being detained there and that the charges of cruel treatment of the inmates are absolutely without foundation. Recommendation is made, however, that the prison characteristics of the institution be changed and Matteawan be placed on a more distinctly hospital basis, that its more capable patients be regularly employed, and that the State Lunacy Commission have complete control over it.

Department of Physiology of Columbia University.—Plans for the extension of the work of the department of physiology of Columbia University are being carried out. Three additions to the staff have been made: Frank H. Pike of Chicago University to be Assistant Professor, Horatio B. Williams of Cornell to be an associate, and Donald Gordon to be an instructor. Dr. Williams is spending the summer in Europe visiting several laboratories and arranging for the purchase of apparatus for electrocardiographic and other work. Professor Burton-Opitz will have charge of the instruction of the medical students, and Professor Pike of much of the work in general physiology. A course in clinical physiology, dealing with the application of physiological methods to problems of clinical medicine has been established. Changes in the laboratories will be made during the present summer. The income of the George G. Wheelock Fund is to be devoted to the extension of the library. The chief professorship of physiology, held by Frederic S. Lee, has been entitled the Dalton Professorship, in memory of John C. Dalton, who was in point of time the first experimental physiologist of America

and gave distinguished services to the College of Physicians and Surgeons for thirty-five years.

Noisy Motor Boats.—Added to its other activities, the New York Health Department has undertaken the suppression of noisy motor boats. A section of the sanitary code provides that all such boats on the waters of New York City shall be equipped with a muffler or other device to do away with the noise of the exhaust. Complaints in regard to the noise made by these boats have been entered by both the Children's Hospital and the State Hospital for the Insane on the Harlem River, and the first arrest, made recently, resulted in a fine of five dollars for the offender.

Civil Service Examination.—On June 17, 1911, the New York State Civil Service Commission will hold an examination for the purpose of filling a vacancy in the position of superintendent or assistant superintendent in the State Hospital Training School for Nurses at a salary of $1,200 a year and maintenance. The position is open to women only.

Water Tanks and Mosquitos.—The Board of Health of New York recently adopted an additional section of the Sanitary Code, reading as follows: "Every tank for holding water, located on the roof or external part of a building, shall be kept covered with a tight-fitting cover, or with an extra fine mesh screen to prevent the access of mosquitos to the water therein; and every such tank shall be ventilated. Every tank from which water is furnished for general use shall be emptied and the inside thoroughly cleaned at least twice a year, and at such other times as may be directed by the Sanitary Superintendent or an Assistant Sanitary Superintendent of the Department of Health."

Watch on Cattle.—The State of New Jersey has recently appointed a new State Commission on Tuberculosis in Animals, which has organized and has divided the State into districts in order to facilitate the work of cattle inspection. Four inspectors will shortly be appointed and the work will be actively prosecuted.

Dr. Wendell Reber, professor of ophthalmology in the Department of Medicine of Temple University, and in the Philadelphia Polyclinic and College for Graduates in Medicine, has been appointed ophthalmologist to the Philadelphia General Hospital in succession to the late Dr. Charles A. Oliver.

Dr. Alfred Wiener has been appointed Consulting Ophthalmologist to the Gouverneur Hospital.

New York State Board of Medical Examiners.—A meeting of the State Board of Medical Examiners, rendered necessary for organization purposes by reason of the death of both Drs. Potter and Ely, respectively President and Vice-President of the Board, was held May 19, 1911, at Albany, N. Y. Dr. Glentworth Reeve Butler of Brooklyn was elected President and Dr. Henry B. Minton of Brooklyn, Vice-President. The Question Committee was reorganized as follows: Dr. Lee H. Smith, Chairman, Buffalo; Dr. Ralph H. Williams, Rochester; Dr. A. W. Booth, Elmira; Dr. Henry B. Minton, Brooklyn. In keeping with the action of the Board at its last annual meeting, it was resolved that on and after January 1, 1912, examination groups in each topic shall consist of 12 questions (instead of 15 as heretofore), the first six of which must be answered by the candidate, and from the remaining six the candidate is to answer four questions of his own choosing.

Essentials in Street Cleaning.—Prevented from being present to deliver his address on "Clean Streets" before the New England Conference on Street Cleaning in Springfield, Mass., on May 17, Dr. George A. Soper, president of the Metropolitan Sewerage Commission, New York, telegraphed an epitome of what he had to say, as follows: "Experience teaches for clean streets. We must organize, systematize, deputize, energize, supervise, economize, and philosophize."

A Plague Hero.—The Carnegie Fund Committee of France recently awarded the Foundation gold medal to the widow of the French doctor, G. E. Mesny, who died while engaged in treating plague victims at Harbin, China. Dr. Mesny was one of the foreign physicians who volunteered their services during the plague in the Far East. He died on January 12, 1911, after having contracted the disease.

Gifts to Charities.—By the will of the late Walter E. Duryea of Montclair, New Jersey, the Roosevelt Hospital, New York, receives a bequest of $15,000 for the endowment of three free beds, one in the men's surgical ward in memory of the testator's father, Edgar E. Duryea, one in the women's surgical ward in memory of his mother, Julia A. Duryea, and one in the children's surgical ward. The Nassau Hospital at Mineola, N. Y., also receives a bequest of $25,000 to be employed for the maintenance of crippled children, and an additional $75,000 contingent upon the death of a third person.

Through the gifts of her former pupils, a bed in memory of the late Miss Mary F. McAleer of New York has recently been endowed in the children's ward of the Beth Israel Hospital, New York.

The Stamford Hospital, of Stamford, Conn., receives $20,000 by the will of the late Miss Elizabeth J. Mead of that city.

By the will of the late Francis Magee of Philadelphia the sum of $5,000 is bequeathed to the Methodist Hospital of that city.

The Presbyterian Hospital of Philadelphia receives a bequest of $5,000 by the will of the late Mary A. Hunter, to be used for the endowment of the William J. McAllister Free Bed.

The New Jersey State Pediatric Society.—A general meeting under the auspices of the New Jersey State Pediatric Society was held in the Lecture Room of the Newark Free Public Library, Friday evening, May 12, 1911. The meeting was called to order by the president, Dr. Henry L. Coit, at 8:45 o'clock. The subject was "A Symposium on the Hygiene of Childhood," and the general subjects covered by the speakers were: (1) The Hygiene of Development, (2) the Hygiene of Environment, (3) Prophylactic Hygiene, (4) the Hygiene of School Life. The speakers were: Dr. Henry Dwight Chapin, Dr. Charles Gilmore Kerley, and Dr. Rowland Godfrey Freeman of New York City. Dr. William Perry Northrup, who had been announced as the first speaker, was absent, owing to illness, and his paper was read by Dr. B. Van D. Hedges. Mr. Henry E. Jenkins also made an address, speaking principally on school hygiene. About one hundred and eighty physicians were present in the audience.

Eastern Medical Society.—At a regular meeting of this society held in New York on May 12 the program consisted of a symposium on the heart. Dr. Bernard Sutro Oppenheimer read a

paper entitled "Factors in the Production of Auricular Fibrillation (Nodal Rhythm)." A paper which dealt with some of the newer methods of investigation in the study of the heart was read by Dr. T. Stuart Hart. The work of the heart in valvular disease was the subject of an address by Dr. W. G. MacCallum. Among those taking part in the discussion were Drs. A. Jacobi, Walter B. James, Morris Manges, Francis P. Kinnicutt, Frank S. Meara, and Louis Peiser.

American Medical Editors' Association.—The forty-second annual meeting of this Association will be held at the Alexandria Hotel, Los Angeles, on June 26 and 27, under the Presidency of Dr. J. MacDonald, Jr., of New York. The Annual Banquet will take place on the evening of Monday, June 26. The following papers will be read: "Relation of the Medical Press to the Public Health and Marine Hospital Service," by Surgeon General Walter Wyman; "The Advisability of Newspapers and Magazines Having Medical Editors on their Staff," by Edgar A. Vander Veer; "Some Things I have Learned as a Western Medical Editor," by Edward C. Hill; "Some Elements of Success in Medical Journalism," by J. M. French; "The Medical Reporter from his Own Standpoint," by E. Franklin Smith; "Physical Therapeutics in the Medical Press," by Arnold Snow; "What Shall We Publish?" by J. R. Phelan; "The Extension of Advertising in Medical Journals," by S. DeWitt Clough; "Medical Expert Testimony," by R. B. H. Gradwohl; "The Hospital Bulletin as a Factor in Medical Journalism," by George W. Kosmac; "The Literary Side of Medical Journalism," by T. D. Crothers; "Privately Owned Medical Journals," by Henry W. Coe; "The Influence of Medical Journalism for Medical Progress," by W. Benham Snow; "Editorial Independence," by T. G. Atkinson. Also papers, subjects to be announced, by C. H. Hughes and William Porter.

Post-Graduate Medical Education.—The delegates of the United States to the International Committee for Post-Graduate Medical Education will maintain a Bureau of Information on Medical Education, particularly post-graduate, at 303 East Twentieth street, New York. All available information on the subject will be kept on file for the benefit of those who inquire personally or by mail about the educational facilities in the different medical centers of the world. All communications should be addressed to "Medical Information Bureau, 303 East Twentieth street, New York, N. Y.," and those requiring an answer should be accompanied by a stamped envelope.

Anesthesia Society.—The next meeting of the Anesthesia Society, New York, will be held at the Hahnemann Hospital, Park avenue and Sixty-seventh street, on Wednesday, May 31, at 8:30 P. M. The program includes the presentation of apparatus, a review of current literature both English and German, and papers by Dr. T. D. Buchanan on "The Clinical Features of Anesthetic Nausea," and by Dr. G. F. Sammis on "Nitrous Oxide Oxygen Anesthesia."

Barber County (Kansas) Medical Society.—At the regular meeting of the society held on May 3, at Kiowa, the following officers were elected for the ensuing year: *President*, Dr W. L. Welsh of Hazleton; *Vice-President*, Dr. W. H. Harris of Kiowa; *Secretary-Treasurer*, Dr. G. R. Waite of Kiowa.

American Society of Tropical Medicine.—The eighth annual meeting of this society was announced to be held in New Orleans on May 18 and 19, 1911, when Dr. C. W. Duval was to demonstrate cultures of *Bacillus lepræ* and other pathological features of leprosy in his laboratory, and a symposium on pellagra was to be held at the Charity Hospital.

Obituary Notes.—Dr. William Robert Anthony Wilson of Pittsfield, Mass., a graduate of Williams College in 1892 and of the College of Physicians and Surgeons, New York, in 1895, who some time ago relinquished his active practice because of ill-health, died at his home on May 14, aged 41 years.

Dr. Benjamin F. Keables of Pella, Iowa, a graduate of the College of Physicians and Surgeons, Keokuk, Iowa, in 1852, and a member of the Iowa State and Marion County Medical Societies, died at his home on May 9, aged 82 years.

Dr. Richard Sappington of Baltimore, Md., a graduate of the University of Maryland School of Medicine, Baltimore, died at his home on May 14, aged 84 years.

Dr. Henry J. Brink of Britt, Iowa, a graduate of the Medical Department of New York University in 1883, and a member of the American Medical Association and the State and County Medical Societies, died at his home suddenly on May 8.

Dr. Andrew J. Bevan of Haverford, Pa., a graduate of the Medical Department of the University of Pennsylvania in the class of 1886, died at his home on May 9, aged 62 years.

Correspondence.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

GOVERNMENT INSURANCE AGAINST SICKNESS—ACUTE INTUSSUSCEPTION IN INFANTS—ALBUMINURIA — ARSENICAL CANCER — NOTES — OBITUARY.

London, May 5, 1911.

Yesterday the government scheme of State insurance, which has been so long promised, was introduced to the House of Commons. It proves to be a vast and complicated plan of compulsory assurance against loss of health and unemployment. The prevention and cure of sickness is the part which concerns the profession and forms a separate division from that of unemployment, which, so far as can be judged for the present, seems likely to be dropped as an over-burden. The insurance is to cover all weekly wage earners. There is also to be a voluntary class to admit persons who are not working for an individual employer but are dependent on work for their livelihood. Workers of both sexes are included. The number of beneficiaries is estimated at about 14,000,000. The benefits are to be medical relief and allowances to the insured and their families during illness. The allowance to doctors is to be fixed at 4 shillings per person per annum, apart from drugs; the amount usually paid by friendly societies varies between half a crown and six shillings. There is also to be a maternity benefit of 30 shillings to cover doctoring and nursing. This is not usually provided by the societies. It is wisely made a condition that the woman shall not return to work for four weeks. Large sums are to be provided for assisting local charities, building and maintaining sanatoria. In every case the al-

lowance is to be conditional on obedience to the orders of the doctor—no sick pay for illness due to misconduct. The machinery of the friendly societies is to be utilized, and in addition county health societies set up and other means of promoting hygiene.

No opinion can be formed of the scheme at present. Indeed, the several parties in the House made no attempt to criticise, but seemed content to respond to an appeal to consider it as outside party, and outside so far I only hear of it as an audacious and complicated effort demanding close study.

Acute intussusception in infants is a condition which every practitioner feels he may at any moment be called upon to meet, though most would gladly be exempt from such a case. At the Medical Society of London Mr. Roughton read on April 24 an account of fourteen consecutive successful laparotomies, all during the first year of life, the oldest child twelve months, the youngest four. All were operated on at the earliest possible moment. In all but one the locality was that of the ileocecal valve and he thought invagination so rare elsewhere that there must be something which favored the occurrence in that region. He considered the diagnosis easy, provided the condition was suspected. The passage of blood and mucus he seemed to think diagnostic, *i.e.*, blood and mucus alone—not if mixed with fecal matter. He would never hesitate to open the abdomen, whether a tumor could be felt or not, when a child passed blood and mucus with little or no fecal matter. The appearance of the child was deceptive. During the first twenty-four or thirty-six hours, in the intervals between the screaming paroxysms, it was difficult to realize that the infant was in the grip of a fatal disease. Often temperature and pulse were normal. As a rule a lump could be detected under the anesthetic, but often not before. It was not always the sausage shape of the text-books—more often it seemed globular. It might be anywhere except in the right iliac fossa, more frequently he found it near the umbilicus. Sometimes it could not be found even under the anesthetic. He contended there was only one cure—laparotomy at the earliest moment possible. When efficient surgery was available distention of the colon with wind or water should not delay operation. But if he were so placed that opening the abdomen was not justifiable he would employ injection, as some cases so treated had doubtless recovered. The last piece of the invagination should be brought into full view to make sure reduction was complete and the cecum and appendix always inspected before closing the abdomen. Neglect of that precaution might lead to what was erroneously called recurrence. He did not believe intussusception ever recurred if it were properly reduced. If cases were diagnosed early and at once operated on, wasting no time on inflation or injection, recovery would almost always follow. In the discussion Mr. Roughton received support from Sir W. Cheyne, who said if he got a case early enough he could not see why the child need die. Mr. Kellock would use inflation for what it was worth and operate on the last inch or so. Mr. Low would do likewise, but inject fluid instead of inflating. Mr. Lett urged inflation where Henoch's purpura was present. Mr. Evans suggested that teething powders were sometimes the cause of irregular peristalsis leading to intussusception.

We have had a two days' debate, closing on Tuesday, in the Medical Section of the R. S. M., on the "After History of Cases of Albuminuria Occurring in Adolescence." Such was the title of the opening paper by Dr. Goodhart, founded on all the cases he had noted in his private case-books during 27 years—237 in number. He had often looked for the condition without finding it, because he did not hit the physiological moment. He liked the term cyclic for what had been called intermittent, postural, functional, or adolescent albuminuria. The last was not appropriate, for he had seen it in adults. Like others he had noticed albumin after food later in the day, so that the mid-morning or after-breakfast appearance was not explained by posture or exercise or both. There might be a good deal at mid-morning, but none at the next micturition. All natural functions were cyclic and all sorts of funny things might be found in the urine at the particular time, acids, phosphates, urates, and so on. Some cases were noticed when the specific gravity was high, some after severe exercise or a heavy meal or other condition. A marked oscillation in the output of albumin was evidence of disturbed function even if grave disease might be behind it. He thus brought all intermitting albuminurias into line—at one end severe cases that might lead to structural changes, at the other conditions of surfeit or sub-toxic states. These came and went without risk to the kidneys and left the subject after a time quite sound. Further, extreme variations of quantity in short periods rendered structural change impossible. In a turgid condition of early sexual development the prostatic secretion might become charged with unnatural exudates, as in old men prostatic hemorrhage may occur and recur. Possibly the passage of urates, oxalates, etc., might wound the membrane. Another cause, he thought, was rapid growth. Another was food-bolting, and the two last often go together. It was an affection mostly of males—he had notes of only six females. Coming to after-history he had long held that adolescent albuminuria had no sinister effect on health or longevity and with due circumspection such cases should not be rejected for life assurance. He admitted that the evidence to prove the correctness of this opinion was very elusive. He had to admit that the condition hung about, coming and going, in some cases for long periods, and therein was a great difficulty of getting information that the patient was really well. Freedom from albumin at last examination was no guarantee that a tendency to discharge had ceased to exist, but in many cases after an interval of years it had not returned.

Dr. R. Saundby remarked that there was too much readiness to consider Bright's disease was present when albumin was found. If no other sign existed they could give a good prognosis.

Mr. Armstrong (of Wellington College) said 15 per cent. of boys in a public school passed albumin. In his cases athletic boys often had it when cross-country running, but they would also have temporary heart failure. Another class he called emotional and said it was not sufficiently known how often extreme emotion like fear would cause it. A third group was purely functional, and a fourth was a lumbar lordosis.

Dr. Collier (of Oxford) found albumin in 130 out of 156 men in training. In oarsmen albumin and casts, some of these granular, were found. He noted in albuminuria after exercise the amounts diminished until after five hours there was none.

Dr. Clement Dukes found 157 out of 1,000 boys

passing albumin and felt sure they did not go on to organic disease. In 1905 he protested against such lads having their education interfered with, their games stopped, and food curtailed. That meant insufficient nutriment for growth.

Dr. Tyson spoke of cases coming on about 20 and going on for 20, 30, or even 40 years. They were not intermittent as they always had albumin. He could not explain them. There was no high tension and though not robust they were not particularly ill, but they did not die.

Since I sent you, a fortnight ago, some current opinions about 606, Sir Jonathan Hutchinson has spoken. This venerable clinical observer seems to retain all his interest in practical questions during his retirement, and what the London Polyclinic would be without him I cannot think. You will doubtless remember that in 1880 he taught that herpes zoster often followed the use of arsenic, and, although at first others looked upon the facts as merely coincidences, they accumulated so fast that arsenical zoster became widely recognized. Later this close observer became convinced of a much more serious danger, viz., that arsenic "could give a proclivity to cancer." In one of his early *Archives of Surgery* and in a recent fasciculus of the New Sydenham Society's Atlas he related cases in detail with some illustrations. His great reputation as an accurate observer and his extensive experience made his opinion seem almost authoritative among his numerous pupils, although a good deal of scepticism prevailed.

The booming of 606, which is essentially an arsenical preparation, has now drawn from him (*British Medical Journal*) a reiteration of his view, which has been endorsed by some foreign writers. He thinks himself "justified in stating that it is proved that the use of arsenic may create a proclivity toward malignant forms of growth." Epithelioma is the most likely but not the only form. The term, "arsenic cancer," he consider misleading, as apt to concentrate attention on cases "unquestionably rare," but which are probably only very exaggerated forms of what in minor degrees may be common. Perhaps the explanation is that arsenic is a depressant of growth which lessens the vigor of the forces of normal animal organization, but permits remotely or after an interval a degraded type of a vegetative sort. It is not to be assumed that prolonged use of the drug is necessary to produce this effect any more than its medicinal action, for this is sometines obtained early. Moreover, a long interval may often be noticed after the use before its usual effect follows.

The College of Physicians has elected to the Fellowship the following members: Drs. H. G. Adamson, E. G. Browne, Sir D. Bruce, P. S. Hichens, E. D. Macnamara, J. A. Nixon, F. S. Palmer, C. G. Seligmann, H. T. Thompson, and H. Williamson.

The final meeting of the Plague Conference at Mukden, says a telegram, took place on April 29, but the recommendations are being kept secret at the wish of the Chinese Government.

A memorial tablet to the late George Busk, F. R. S., president of the Royal College of Surgeons in 1871, was placed over a bed endowed by his daughters in the Dreadnought Hospital, of which he was consulting surgeon. His name will be familiar to you as one of the greatest surgeons of the last generation.

The death has occurred of Lieutenant-Colonel I. B. Lyon, I. M. S. (retired), formerly professor in the Grant Medical College (Bombay) and analyst to the Indian Government. He had also been physician to the Jamsetji Jijibtroy Hospital. He retired in 1892 from the service he had entered in 1865. He was created a C. I. E., was the author of "Food Tables for India," and a "Text-book of Medical Jurisprudence for India."

Dr. G. A. Pedley has died at Winchester at the age of 50. He was for ten years surgeon to the Trawaldy Company, Burmah. He also served as surgeon-captain to the Upper Burmah Rifles, and was surgeon to the Home for Lepers, Mandalay.

Mr. Samuel Knaggs, who died on April 23 at the age of 82, was consulting surgeon to the Infirmary at Huddersfield, where he passed his professional career. He was greatly esteemed as a man as well as a surgeon. He wrote "Unsoundness of Mind" and contributed papers on other subjects.

MEDICAL CARE OF THE NATIVES IN THE PACIFIC ISLANDS.

(From Our Manila Correspondent.)

SAMARAI, PAPUA, March 15, 1911.

UPON the island of Yap the German government maintains a physician and a small hospital. The only quarantine inspection of vessels from foreign ports which is made in any of Germany's Pacific island possessions takes place there. The treatment for natives in free, but very few avail themselves of the medical facilities and with the exception of the medical aid required by the twenty odd European cable employees the duties of the medical officer are not very onerous. Some attempt has been made toward vaccination, but this has not been done in a systematic manner so as to include all of the natives.

At Kaiser Wilhelms Hafen for hospital purposes a very pretty little island has been set aside. Upon this there have been constructed a number of small crude wooden pavilions in which about 100 natives could be cared for. Just at present there are about a dozen patients. Another small and better finished and furnished pavilion has been provided for Europeans. In the immediate vicinity there is a bungalow which is used as a residence by the medical officer. Great patience and perseverance are necessary to induce the natives to enter the hospital when sick. This opposition, or perhaps apathy, is being gradually overcome, for here as elsewhere the benefits derived by those who have been in the hospital are extolled when they return to their own people and others are induced to come thereby. An examination of the hospital records showed that tropical ulcers, beriberi, pneumonia, bacillary dysentery, yaws, and tinea imbricata are very common. The microscopical report showed that uncinariasis and filariasis are frequently encountered. In order to introduce the benefits of modern medicine more rapidly it is customary for the medical officer to visit native towns and ascertain the names of those who are in the need of attention. These names are then forwarded to the Governor who sends members of the native soldiery out to bring the sick to the hospital. This is done in a kindly way without the show of much force and it is said to be producing satisfactory results. Considerable vaccination is done by sending native runners out several days in advance to advise the headmen of a town that the doctor will arrive in a few days and that they are to arrange to have the populace present itself

for inoculation. Vaccination is fairly popular. The natives are very fond of scars and nearly all of them are covered with elevated specimens which have resulted from self-inflicted wounds which were kept open by frequent scratching or by the introduction of foreign substances like sand, bamboo, shells, and so forth. The excrescence which results from the average vaccination is scratched off at the proper time and the resulting large scar is very dear to the native. Dr. Hiesegang, the medical officer at Kaiser Wilhelms Hafen, reports that many natives constantly apply for the loan of vaccine and a lancet so that they may vaccinate themselves again for the purpose of making a scarification of a size that will produce a scar which they deem suitable.

At Rabaul, which is in New Pommern and the capital of German New Guinea, a very much larger hospital is maintained and two medical officers are stationed there, as well as several trained nurses and sisters of the German Order of Deaconesses. The hospital is built upon the pavilion plan and has a capacity of 500. At the time of my visit it contained 109 patients. The pavilions are about 24′ x 60′, built cheaply of wood, covered with galvanized iron roofs and have a capacity of 50 patients. With this number present, however, many of the patients sleep outside under the overhanging roof which serves as a veranda. There is a small building for an outpatient service, one which is used as a general office and waiting room, and one as a disinfecting building. In addition there are a kitchen and the necessary outbuildings for toilets, baths, stables, etc. The character of the diseases treated in the hospital at Rabaul is much the same as at Kaiser Wilhelms Hafen, but everything is upon a much larger scale.

At Herbertshöhe, which is about ten miles down the bay from Rabaul and the site of the former capital, a similar but smaller hospital is maintained and has one doctor and several nurses and sisters of the Order of the Sacred Heart.

This completes the list of the doctors regularly stationed in the German possessions for the relief of the sick. There are several connected with the government staff who act in an advisory capacity with regard to sanitation, but very little has been accomplished in this direction. Occasionally doctors attached to German naval vessels assist in relieving distress. There are no native practitioners and there are no private doctors of any nationality.

The entrance salary of those entering the German colonial medical service is approximately $2,000 per annum, which includes a furnished house but no subsistence. Those stationed in the larger places have a good opportunity to increase their income by private practice.

In the Gilbert islands with the exception of a few missionaries there is no provision for the relief of the poor.

The eastern part of New Guinea is under the jurisdiction of Great Britain and is known as Papua. This and the neighboring islands are administered by Australia and the Commonwealth maintains a physician at Port Moresby and one at Samarai.

At Samarai a quarantine inspection is made of vessels arriving from foreign ports and a small island has been set aside for quarantine purposes. There are buildings for isolating the sick and contacts and facilities for disinfecting vessels. A hospital is maintained for the treatment of the indigent sick and another for the treatment and isolation of venereal cases.

Recent Experimental Work on the "Fusion" of Nerves and Its Practical Bearing on Infantile Paralysis. Report of a Case of Infantile Paralysis Treated by This Method. H. O. Feiss.
A Case of Hemiatrophy from Scleroderma. P. C. Knapp.
The Towns-Lambert Treatment for Morphinism and Alcoholism. R. C. Cabot.
A Review of 214 Cases of Extrauterine Pregnancy at the Massachusetts General Hospital. W. P. Coues.
Two Cases of Abdominal Pregnancy, One at Term. E. Reynolds.
Report of a Case of Full-Term Intraabdominal Pregnancy. J. W. Lane.

The "Fusion" of Nerves.—H. O. Feiss states that this is nothing more nor less than a method which attempts to render permanent the arrangement of the fibers in that stage of regeneration when they run in more than one direction. It is a method for taking advantage of the confused nerve pattern of the scar in the transitory stage and fixing that pattern in the hope that, when regeneration is finally completed, the fibers will have grown down different tracts from those which they originally occupied, thus defeating chemotaxis. So in a case of paralysis, if some of the fibers in the nerve are degenerated and their sheaths are empty, the question arises whether the interposition of a proper scar in the course of that nerve may distort its nerve pattern so as to enable the empty tracts to become occupied again with new fibers. Not only this, but one may also inquire whether some of the branches that form on the sprouting ends of the divided axis-cylinders may also be made to enter tracts which have previously been empty, thus gaining not only a new distribution of fibers, but also an actually greater number.

Hemiatrophy from Scleroderma.—P. C. Knapp states that probably the rarest form of hemiatrophy is that associated with scleroderma, of which he has been able to find only six reported cases.

Morphinism and Alcoholism.—R. C. Cabot speaks highly of the Towns-Lambert method of treating morphinism and alcoholism. He has already seen results sufficient to confirm him in the belief that, aside from suggestion and any notable psychical impressions the treatment has great value, especially in the cure of the morphine habit.

Extrauterine Pregnancy.—W. P. Coues reviews a series of 214 cases of this condition treated at the Massachusetts General Hospital. He concludes that irregular flowing seems to play the important part given it in the books as a symptom of extrauterine pregnancy. The importance of a long period of sterility as a cause of extrauterine pregnancy does not seem to be borne out by the statistics. Conditions possibly leading to extrauterine pregnancy: The fact that cystic ovaries, disease of the opposite tube, adhesions, or a previous miscarriage occurred in over 83 per cent. of 202 cases is suggestive, and is in agreement with authorities as to the possible relation of such conditions to extrauterine pregnancy. The fact that in only 26.5 per cent. of 207 cases the pain was sudden is of interest. In about three-fourths of the cases the sudden, severe pain was preceded by pain of less severity, coming on gradually. Of considerable interest is the leucocytosis observed in the cases in shock. This is apparently a perfect example of leucocytosis after hemorrhage. The finding of a temperature of 100 or over in 43.4 per cent. of the cases, and of a temperature of 101 or over in 14.4 per cent. of cases, is also of interest. Ordinarily it is supposed these cases rarely have any fever. As regards hemorrhage, some observers with much experience in this subject any that active hemorrhage actually seen at operation occurs so rarely as to be practically negligible. It occurred in 4.4 per cent of all the cases operated on. It is possible that the hemorrhage was in some cases started up by operative manipulation. Immediate vs. delayed operation: The statistics show

that it is best to wait for a time before operating on the cases in shock. Twenty-five per cent. mortality occurred in those operated on in shock, 8.3 per cent. mortality in those for whom the operation was delayed for a time. Active stimulation and blood-pressure-raising drugs seem to be best given after the bleeding points in the tube are secured. Rest and morphine while waiting are most important. Waiting any length of time with a case of extrauterine pregnancy in good condition is dangerous, since it has been shown that bleeding may recur at any time, so that in a few hours the patient may be again in a desperate condition.

Abdominal Pregnancy.—E. Reynolds reports two cases of this condition, one of which was at term. Both these cases were seen after the death of the fetus, and both were operated upon after necrosis of the placenta was well established; they, consequently illustrate only one phase of this subject. Both were operated upon by the same method, *i.e.* walling off the general cavity, opening of the gestation sac by careful dissection with the fingers, removal of the fetus and of such portion of the secundines as could be readily separated, and packing of the gestation sac with gauze. The author believes that the keynote to success in such cases rests in selecting for the time of operation a date long enough after the death of the fetus to permit the practical cessation of the uteroplacental circulation, but before the patient begins to show the cachexia which must necessarily attend the absorption of so large an amount of necrotic material. He would place it in the second or third week after the death of the fetus, the choice within these limits being determined by the progress of the patient's condition. The essential technical points are a wide incision, thorough walling off of the general cavity if this has not already been effected by nature, great care in ascertaining the position of the intestines before the gestation sac is torn into, and avoidance of any attempts at forcible removal of the placenta.

Abdominal Pregnancy at Full Term.—J. W. Lane reports a case of this condition.

New York Medical Journal.

May 13, 1911.

Asthenia Universalis Congenita. C. L. Greene.
A Contribution to the Study of Fats and Lipoids in Animal Tissue. The Lipoids in Immunology. J. Wright.
A Series of Studies of Nervous Affections in Relation to the Adjustments of the Eyes. G. T. Stevens.
A Case of Typhoid Osteomyelitis Successfully Treated with a Vaccine. R. C. Rosenberger.
Pupillary Disturbances in the Alcoholic Psychoses. F. M. Barnes.
Therapeutics of Syphilis. V. C. Pedersen.
A Bacteriological Study of the Human Bile. Especially as to the Presence of the Typhoid Bacillus. P. F. Williams.
Visceroptosis. An Improved Abdominal Binder. H. Weinstein.
The Open Treatment of Fractures. W. H. Taylor.

Asthenia Universalis Congenita.—C. L. Greene agrees with Stiller that an abnormally fluctuating or actually floating tenth rib is almost pathognomonic of this condition. Among the structural stigmata are small features, soft fine skin, slender figure, long thorax, hypoplasia of heart and blood-vessels, sluggish pulmonary expansion, gastroptosis, anemia, movable kidneys, and neurasthenia.

The Lipoids in Immunology.—J. Wright, in bringing to a close his review of the activities of the lipoids in vital processes, states that starting from a specific standpoint, that of tonsillar function, he has attempted to develop a wider consideration of the question of the lipoids in the tissues, but while he has urged that it is misleading to expect from such study the discovery of anything specific in their action, since it is dependent upon fundamental principles in chemophysics, he has tried not to lose from view their importance in the mechanism of the surface infection of the lymphoid material in the throat.

Adjustment of Eyes.—G. T. Stevens describes the various forms of facial expression associated with abnormal adjustments of the eyes.

Typhoid Osteomyelitis.—R. C. Rosenberger reports a case of this condition successfuly treated with a vaccine.

Pupils in Alcoholic Psychoses.—F. M. Barnes concludes both from the few cases he reports and from the literature that, although pupillary anomalies occur quite infrequently among alcoholics and particularly the Argyll Robertson pupil is rarely seen, still it is plainly evident that the occurrence of this diagnostic sign cannot always be taken as final evidence of the presence of organic cerebral disease.

Therapeutics of Syphilis.—V. C. Pedersen continues his article on this subject.

Bacteriology of Human Bile.—P. F. Williams examined 121 specimens of bile, and 12 calculi. Of this number, organisms were recovered in 80 cases, and from the calculi organisms were recovered in 6 instances. The organisms that were observed most frequently were those of the colon type. In 37 pure cultures of the colon bacillus were present, and, in association with other organisms, *Bacillus coli* was observed 35 times. The typhoid bacillus was recovered in two instances, one, in which typhoid fever had existed thirteen years previously, and in the second instance, from a person dying as a result of typhoid perforation.

Visceroptosis.—H. Weinstein describes a new abdominal binder that he has devised for this condition.

Open Treatment of Fractures.—W. H. Taylor describes a simple method of insuring perfect anatomical reduction.

The Rôle of Dreams in Etiology. F. X. Dercum.
The So-Called Œdipus-Complex in Hamlet. J. H. Lloyd.
Chronic Glanders in Man, Report of a Case; Patient Treated with Glanders Vaccine. Apparent Cure. W. C. Cramp.
Case of Choked Disc and Progressive Blindness Due to Sarcoma of the Brain. J. B. Thomas.
Report of a Case of Anencephalus. D. S. Kalayjian.
Report of Case of Bronchopneumonia, Showing Positive Brudzinski Neck and Collateral Signs. M. J. Loeb.
Treatment of Cancer with Body Fluids and Cancerous Ascitic Fluids. E. H. Risley.
Chemical Dermatitis from Incompatible External Applications. A. M. Mendenhall.
A Peculiar Case of Intestinal Obstruction. I. Brown.

Dreams in Etiology.—F. X. Dercum criticizes Freud's theory as applied to dreams. He considers that Freud's method induces a sort of autohypnosis and he does not agree with him that the mind exercises a sort of psychic activity in the deepest sleep. He agrees with Samuely that dream conceptions arise just before the sleeper awakens and are part and parcel of the act of awakening. The dream is afterward constructed on the materials they furnish. In the dream analysis of Freud, as well as in the other forms of psychoanalysis, both the physician and the patient are in an expectant mental attitude and there is in both cases a suggestion at work. The rôle that dreams play in etiology, he thinks, is very doubtful; they are probably always symptomatic and never causal, and their symptomatic value is of little consequence.

Freud's Theory and Hamlet.—J. H. Lloyd arraigns severely the explanation of Hamlet's alleged insanity based on the Freud psychological theories. He speaks of the obsession of sexual ideas which seems to rule the whole Freudian school and takes the "Œdipus-complex" offered by Jones for Hamlet's mental condition as a striking example of such obsession. Jones seems to have made out that Hamlet had an erotic feeling toward his mother which would appear to most readers of the play very unnatural if not impossible, taking in all the supposititious conditions. The author states that we are in an era of what may be called subterranean psychology and are invited to dive into the subconscious, the "subliminal," and into the dark underground recesses of the mind to

search for the data of a new science. Can it be that the whole Freudian phenomenon is a form of sexual neurasthenia breaking out among a class of idealistic men and women? The author does not believe that there is as much mystery in Hamlet's behavior as the commentators make out. It is impossible to classify his insanity as such or make it accord with our scientific ideas.

Chronic Glanders in Man.—W. C. Cramp states that cases of chronic glanders can be easily overlooked and multiple abscesses, especially on the extremities, occurring without known cause should excite suspicion, as such occur in 80 per cent. of cases, as shown by Robin. In the case reported by the author there was no direct association with horses and no known abrasion or wound, or history of such, that would appear to be the cause of the infection. There was no nasal discharge at any time and no bacilli were found in the sputum, but the cultures from inoculated guinea-pigs showed characteristic *B. mallei*. Six weeks after the first apparent cure the patient had a relapse, but since then the treatmeant again caused disappearance of symptoms and the patient continued well as long as he was under observation, a period of over eighteen months. Extreme exposure in bad weather seemed to be a predisposing cause. The diagnosis was confirmed by laboratory methods and reaction to vaccine injections.

Choked Disc and Sarcoma of the Brain.—J. B. Thomas reports a case in which the tumor was precentral and the accompanying optic neuritis was very severe. Paton concludes that precentral tumors are nearly always associated with a fairly severe neuritis, whereas postcentral tumors are nearly always associated with a moderate neuritis. It is unnecessary to remind the oculist that the severity of the optic neuritis should be judged, not so much by the loss of vision as by the height of the swelling of the disc, turgescence of the retinal vessels, the extent of hemorrhages and patches of exudate. The eye on the opposite side of the tumor was first affected.

Anencephalus.—D. S. Kalayjian reports a case of this condition presenting the following points of interest: 1. The birth of two abnormal fetuses from the same mother at an interval of twenty-two years, all the other children being normal. 2. Both of the monsters were females. 3. A possible relation of hydramnion to anencephalus.

Brudzinski's Sign in Pneumonia.—M. J. Loeb reports a case of bronchopneumonia in which Brudzniski's neck and contralateral signs were elicited.

Treatment of Cancer.—E. H. Risley states from his experience that the various transudates and exudates of the body, cancerous and non-cancerous, have no effect in retarding the growth of cancer in mice. The use of cancerous ascetic fluid from patients in the active or even moderately resistant stages of the disease has no permanent effect in preventing or checking the growth of cancer, or permanently benefiting the cancer patient. The other non-cancerous body fluids are even more inert. Temporary beneficial effects may be noticed for periods of one to five months, but the course of the disease is in no way permanently retarded. Temporary relief from pain, especially in uterine cases, and in other cases in which large doses can be given, and retardation of the growth for periods varying from one to five months may be expected in a small percentage of the cases. Noticeable benefit in the general physical condition has resulted in one patient with cancer of the ovary by the injection of her own fluid.

Chemical Dermatitis.—A. M. Mendenhall reports a case of this condition resulting from the use of incompatible external preparations, which produced the irritating biniodide of mercury.

Intestinal Obstruction.—I. Brown reports a case of intestinal obstruction caused by the eating of dried apples without mastication.

The Sensibility of the Alimentary Canal in Health and Disease. A. F. Hertz.
The Symptomatic Vagaries of Partial Pyloric Obstruction. A. E. Maylard.
Some Indications of Inborn Proclivity to Gout. Sir Dyce Duckworth.
On the Suprapubic Transverse Fascial Incision in Gynecology. T. Wilson.
Aneurysm of the Innominate Artery; Proximal Ligature; Recovery. P. Sargent.
On Reversible Pulmonary Crepitation in Cardiac Failure. A. Morison.
Infant Mortality. W. E. Heilborn.

Sensibility of the Alimentary Canal.—A. F. Hertz states that hunger consists in a general sensation of malaise and weakness in the body as a whole and a local sensation of emptiness in the abdomen. The latter is due to the periodical motor activity of the stomach and intestines during fasting, when the sensory nerves are in a condition of hyperexcitability. The only immediate cause of true visceral pain is tension; this is exerted on the muscular coat of hollow organs and on the fibrous capsule of solid organs. The sensation of pain in the alimentary canal is due to a more rapid or greater increase in tension on the fibers of its muscular coat than that which constitutes the adequate stimulus for the sensation of fullness. Pain in diseases of the alimentary canal is most frequently true visceral pain; it is sometimes due to spread of the disease to surrounding sensitive structures or to tension exerted on the peritoneal connections; and, lastly, it may be situated in the skin, muscles, and connective tissues, to which it is referred from the segment of the central nervous system, which receives the afferent nerves from the affected organ. Tenderness in diseases of the alimentary canal is most frequently due to hyperalgesia of the skin, voluntary muscles, and connective tissues supplied by the segment of the central nervous system, which receives the afferent nerves from the affected organ. It may also be due to increase in tension within the organ produced by the external pressure giving rise to the adequate stimulus of visceral pain; this is rare in the stomach, but comparatively common in spasmodic conditions of the colon and in appendicitis. Lastly, it may be due to the spread of the disease to the parietal peritoneum. Visceral sensibility is exaggerated by training in hypochondriasis, and visceral and referred sensations are exaggerated by the irritable condition of the central nervous system in neurasthenia and anemia.

Partial Pyloric Obstruction.—A. E. Maylard states that the points of most significance in partial pyloric obstructon are intermittent attacks of dyspepsia, coupled at such times with the physical signs of gastric peristalsis or gastrectasis in often otherwise healthy patients.

Inborn Proclivity to Gout.—Sir Dyce Duckworth contrasts the gouty and the strumous diatheses and states that there is a remarkable antagonism between these two family proclivities. Thus, the gouty habit is markedly resistant to tuberculous invasion. In cases of intermarriage of gouty and strumous persons one meets with a blended constitution in the progeny, and it is of interest to study the outcome of it. Tuberculosis may assail such a progeny, but the process is liable to marked arrest, and the prognosis generally in such cases is distinctly better and encouraging. Among the manifestations of the gouty habit in early life are "growing pains," in the lower limbs without any pyrexia. Attacks of classical gouty arthritis may sometimes, though rarely, supervene even before puberty, and deposits of urates to the extent of tophi, have been met with early in the second decade. There is an early evidence of the inability to digest malt liquors and acid wines in small quantities. Toward the fourth decade there may occur lumbago, sciatica, and neuritis in

various parts of the body, together with vague pains and affections of tendons and their sheaths, fibrositis, and fibroid nodules. Deep-seated pains occur in the bones of the arms—*e.g.* condyles of the humerus, os calcis, etc., apt to be lingering and tedious, with pains in the tongue, tenderness of the dental periosteum, and creakings in the neck.

Transverse Fascial Incision in Gynecology.—T. Wilson in summing up the advantages which he conceives that the transverse fascial incision offers over the longitudinal incision in suitable cases, states that by far the most important is the lessened risk of ventral hernia. In the next place in the ordinary run of gynecological operations this incision affords easier access and more ample room than the longitudinal incision, and especially than the paramedian incision of Lennander. Finally, it is possible that the cosmetic effect may be deemed by some to be of importance; the scar is linear and is concealed by the pubes and by the natural folds of the abdominal wall.

Aneurysm of the Innominate Artery.—P. Sargent reports a case the chief points of interest in which are, 1, the advanced age of the patient; 2, the ease with which, owing to there being a portion of healthy artery between the aorta and the aneurysm, the operation was accomplished; 3, the lateness of onset of, and the complete recovery from, a slight hemiplegia; 4, the permanent obliteration of the aneurysm in spite of the fact that the walls of the artery could not long have remained approximated by the ligature; 5, the distance between the point of obliteration of the subclavaian artery and its vertebral and the origin branch; and lastly, the complete relief to all the symptoms afforded by the operation.

Reversible Pulmonary Crepitation in Cardiac Failure.—A. Morison calls attention to the fact that the well-marked crepitation denoting pulmonary congestion in the most dependent part is abolished, usually altogether, and almost always, by a single rotation of the patient on his own axis in bed. It is always indicative of a grave degree of cardiac failure when reversible from one lung to the other.

Infant Mortality.—W. E. Heilborn states that the diminution of infant mortality will be brought about only when the state will adopt the following measures: 1. Education of those about to become mothers. 2. A law preventing all women about to become mothers from working in a factory or mill, and this should hold good during the whole of their childbearing period. 3. A system of dairies through which the public can be supplied with pure, fresh milk. 4. Every physician who delivers a child should look upon that child as his patient, and it should be under his immediate supervision during the whole of its infancy. 5. An efficient army of competent nurses should visit every infant each week and immediately report to the physician if the infant does not seem to be thriving. It should be made illegal to insure an infant's life.

A Drainage Tube for Suprapubic Cystotomy, Liver Abscess, and Abdominal Cysts. L. McGavin.

Hemorrhoids.—E. S. Bishop states that the radical method of obliterating the perineal portion of the internal hemorrhoidal plexus (Whitehead's operation) is the one method which can be relied upon to prevent any return of the condition. In order to carry this out effectually the whole perineal portion of this plexus up to the pectinate line should be removed, and the submucosa beyond brought down and firmly fixed to the skin. Failure to do this is at the root of organic stricture of the anus following an operation. In many, at least, of the cases of organic stricture following operation dissection out of the resulting scar tissue, freeing of the external sphincter, and bringing down of the submucosal layer to the skin will result in a cure.

Operative Treatment of Rectal Cancer.—J. W. Smith recommends the perineal method in operating on cancer of the rectum, for the following reasons: 1. A better view of the upper part of the pelvis, as far as the sacral promontory, can be got. This facilitates a higher division of the fat and tissues in the mesocolon. 2. The freeing of the pelvic colon is rendered easier. Thus the new anus can be kept in the normal position, and experience shows this to be better than the sacral or gluteal anus. The sacral anus, situated directly below the prominent ridge of the lower border of the sacrum, which stands out more after the coccyx has been removed, is on a depressed and uneven surface, and is difficult to manage afterwards. Being in a rigid position, where it cannot retract between the folds of the buttock, it is also more liable to accidental leakage if the feces are soft or fluid. 3. Separation from the prostate is easier by the perineal route, and the early opening of the peritoneal cavity through the rectovesical pouch in front rather than higher up on the lateral walls makes the later stages easier. 4. The lateral sacral incision takes longer to heal than the perineal one. After the latter, healing practically by first intention occurs not infrequently. 5. The perineal position is preferable for the administration of the anesthetic and the prevention of shock.

Operations on Kidneys and Ureters.—E. Deanesly states that a well-planned operation on the kidney should satisfy the following requirements: The kidney should be exposed in such a manner that it can be not only palpated and inspected, but completely isolated from its surroundings and drawn outside the body. In the term "kidney" the author included for this purpose the pelvis and first two inches of the ureter. Nothing less than such a complete exposure, or the possibility of effecting it if required, will enable the surgeon to deal satisfactorily with all contingencies. The normal incision should be made directly over the twelfth rib and the whole length of the latter should be excised from the tip to the angle. The best position of the patient is the prone one, with the pelvis resting on a large cylindrical air-cushion. As regards catheterization of one or both ureters as a routine procedure before operation, the author believes that in many cases it is better, safer, and simpler to make a direct exploration of both kidneys at the same operation. There is no part of the ureter which cannot be exposed surgically by an extraperitoneal incision from above. In the case of calculus in the ureter, if the impaction of the stone is an affair of long standing the author is in favor of exploring the kidney before cutting down on the ureter.

Appendicular Dyspepsia.—R. C. B. Maunsell defines this condition as a group of symptoms, and perhaps signs, which point so strongly to organic, gastric, or duodenal disease that it is only by most careful examination or by the supervention of definite appendicular symptoms that a correct diagnosis is probable. When making a diagnosis one must exclude other causes of reflex pain and vomiting, especially causes arising from the pelvic organs, kidneys, and gall-bladder. The latter and bile-ducts are the most difficult pitfalls to guard against.

Deaths Following Gastrojejunostomy.—C. H. Whiteford reports three cases, which occurred within a period

of three years, and which illustrate deaths from septic pneumonia, cerebral hemorrhage (or thrombosis), and acetonemia. The features common to all three cases were: Operation was performed with the object of preventing death from starvation, the result of pyloric obstruction. The anesthetic was ether. On being returned to bed after operation the patient was at once placed, and nursed throughout, in the Fowler position, saline solution being administered per rectum. The gastrojejunostomy was that of the Mayo clinic, that is, posterior, no loop, antiperistaltic, with an opening of 2½ to 3 in. During the time which elapsed between operation and death, the anastomosis acted perfectly.

Pathology and Treatment of Fistulæ.—H. Drummond states that fistulæ, whether complete or incomplete, nearly always have their origin in abrasion of the bowel, which leads to infection of the tissues by absorption of septic matter. Complete fistulæ are much more common than the internal and external varieties, which may be said to be comparatively rare, especially the latter. These (the so-called external) are nearly always cases of complete fistulæ in which the internal opening proves to be peculiarly elusive, and they resist treatment until it has been found and dealt with.

Acute Abdominal and Pulmonary Conditions.—G. G. Wray states that acute pulmonary conditions in certain stages simulate very closely the signs and symptoms of acute abdominal lesions and *vice-versa*. Nor is it generally recognized that the two are frequently combined. It is not uncommon, for instance, to find acute pneumonia combined with a pneumococcal infection of the appendix going on to suppuration. It is, perhaps, better known how frequently chest conditions supervene on acute abdominal lesions. Cases of abdominal lesions seen not quite at their inception sometimes show marked signs of bronchitis, and this bronchitis clears up when the abdominal condition is relieved. This is especially seen in children, and occurs fairly frequently in those who have some chronic obstruction of the bowels. In making a diagnosis of acute abdominal mischief, examination of the chest should never be neglected, and the converse is also true.

Transmission of Trypanosoma Lewisi.—C. Strickland concludes that infection of rats with *T. lewisi* is caused by the rats' act of eating infected fleas. It is not caused by contamination of the rats during a short time, nor by their being bitten by the fleas. Many more fleas are infective than cause infection in Nature. The infective form of the trypanosome, which is probably the "small trypanosome" of Swellengrebel and Strickland must reach the blood through the gut wall. It is possible that other trypanosomiases may be transmitted by perhaps even non-blood-sucking creatures.

A New Drainage Tube.—L. McGavin describes the drainage tube that he has devised for use in cases of suprapubic cystotomy, liver abscess, and abdominal cysts.

Deutsche medizinische Wochenschrift.

May 4, 1911.

Weil's Disease.—Hector and Otto write at great length on this relatively obscure condition, the eponymic title of which has no doubt been applied to various syndromes which possess in common an acute epidemic incidence with high fever and jaundice. Thus far no bacterial causation has been found to unify these syndromes, which differ notably from one another in certain respects. Cases in troops studied by the author showed congestion of the conjunctivæ and slight angina, severe headache and myalgia, nausea, and at times vomiting and renal irritation including albuminuria and casts. These toxic symptoms attained their maximum on or before the fourth day. Jaundice did not always develop (only 30 per cent.) and the liver was enlarged in about half the cases, the spleen in about one-third. After defervescence patients almost invariably complained of hunger—this despite the fact that the fever of the first few days reached 40° C. and patients seemed to be very sick men. The pulse was not correspondingly high—not above 110—and after defervescence it fell to 50 and even lower. Relapse sometimes occurs and in some epidemics is a feature. The affection has now been studied in garrisons in many German towns. It occurs almost always in hot weather. Mild cases occur side by side with the full syndrome. There is no transmission from man to man directly, and the affection appears to be one in which an ultravisible virus is inoculated by some insect. This calls to mind the origin of yellow fever, and Weil's disease also resembles the latter in other ways. Another similar origin may be attributed to pappataci fever. The "summer fever" of Italian authors, which attacks troops, and which is the same as the "dog disease" of Austrian soldiers, seems to be of the same etiological type, and Italian scientists have recently communicated summer fever to both man and apes not only directly but indirectly through infected pappataci.

Psychogenic Pruritus Vulvæ.—Walthard, as a gynecologist thoroughly conversant with all the forms of this affection which have a material origin, describes at much length a psychogenic type. The latter is not limited to the genitals but usually involves the anus and perineum. While he does not insist on the presence of a hysterical substratum or basic manifestations of that character, the affection usually supervenes after psychic trauma, and in association with palpitation, precordial oppression, insomnia, irritability, mental weakness, etc., the picture therefore inclining to that of neurasthenia. The sensations comprise more than itching, for burning is associated with the latter and psychogenic algias may sometimes occur as in a case of pain referred to the symphysis which the author cites. All these hyperesthetic and hyperalgesic phenomena originate in the cortex, and cannot be reached by local measures or drugs unless of course by suggestion. The author states that Freud's psychoanalytic method for laying bare the causes of the psychic shock is the sole rational therapeutic procedure. The "neurasthenic way of thinking" must be broken up.

Case of Vagitus Uterinus.—Rothschild relates a case of this very rare phenomenon, the existence of which is disbelieved by many practitioners. The mother was under chloroform narcosis, waters had been ruptured for 17 hours, breech presentation, forceps applied to breech, air entering vulva meanwhile. The child cried twice *in utero* and was heard by a number of those present. As it was necessary that no time be lost in extracting, the phenomenon could not be further investigated; but as soon as the head had cleared the perineum the child cried lustily. The midwives and grandmother who had heard the cries *in utero* professed at first to believe that these were only intestinal sounds, evidently from fear of ridicule by the accoucheur. When they learned that the latter regarded the case as a genuine intrauterine cry, they admitted that their conviction had really been the same. Some 60 cases only are upon record and these occurred practically without exception in abnormal presentations or labors in which manual or instrumental measures were required for delivery.

Gallstones.—J. B. Deaver states that symptomless gallstones are now known to be a rarity. Severe and disabling indigestion of non-committal variety is often the result of biliary catarrh with or without stones. There is no remedy as sure as surgery. In the long run there is no remedy as safe as surgery.—*Long Island Medical Journal.*

Book Reviews.

Die Syphilis-Behandlung mit Salvarsan (Ehrlich-Hata 606) nebst einer systematischen Zusammenfassung der bisher veröffentlichten Literatur. Von Dr. Kurt von Stokar, Hautarzt in München. Preis, Mk. 1.20. München: J. F. Lehmann's Verlag. 1911.

This is a small brochure of twenty-five pages of text and a list of more than two hundred publications relative to the subject. The results, opinions, and teachings of many writers are excerpted, the more important appearing in italics. Many different methods of administration of the drug are described, the majority of which "died a-bornin."

Manual of Cystoscopy. By J. Bentley Squier, M.D., Professor of Genito-Urinary Surgery, New York Post-Graduate Medical School and Hospital, and Henry G. Bugbee, M.D., Instructor in Genito-Urinary Surgery, New York Post-Graduate Medical School and Hospital. Price, $2.00 net. New York: Paul B. Hoeber, 1911.

This little manual is intended for beginners in cystoscopic study, and although claiming 117 pages, contains actually less than 46 pages of text. The authors' attempts to keep their work within small compass have led them to the other extreme, thereby omitting much necessary cystoscopic teaching. The text is illustrated by twenty-six plates, of which nineteen are colored. Of the different sections of the book, those on technique of cystoscopy of the normal bladder with the direct instrument, cystoscopic pictures of the normal bladder, and cystitis are the best. Nothing can be said in favor of their disjointed literary style.

Syphilis, its Diagnosis and Treatment. By F. J. Lambkin, Col. R.A.M.C., Lecturer on Syphilology, Royal Army Medical College, London; Late Specialist at the Army Headquarters, India, etc.; with preface by Sir Frederick Treves, Bart., G.C.V.O., C.B., LL.D. Price, $2.25 net. New York: William Wood & Co., 1911.

In these days of frenzied writings on syphilis it is a delight to encounter such a sane and conservative work as Col. Lambkin's. From the history of the disease he leads the reader through its pathology, clinical course, diagnosis and prognosis, treatment of the chancre, secondary period, tertiary manifestations, affections of the nervous system, and para- or quaternary syphilis. The last third of the work is devoted to treatment, being divided into sections on general treatment, inunction treatment, intramuscular method, and its technique, and the arylarsonate and other modern methods. The tables of differential diagnosis of chancres are well chosen and excellently arranged. The section dealing with the secondary period relates the different forms of cutaneous eruptions, describes the various lesions of the mucous membranes, and discusses in sufficient detail all other occurrences in this period. Chapter nine on para- or quaternary syphilis, contains nothing new nor any personal opinions or statistics. It is the chapters on treatment which above all deserve praise, since the author's large experience gives weight to his utterances. He points out the advantages and disadvantages of the ingestion, inunction, and intramuscular methods of treatment, disclaiming infallibility for any particular one, but expressing preference for the intramuscular injection of metallic mercury after twenty-five years observation of its results. The chapter on the arylarsonate preparations has evidently been hurriedly appended, as insufficient consideration has been accorded salvarsan as an auxiliary drug. The technique of its administration as herein described is obsolescent. The work ends with a brief chapter on administration of iodides and directions for staining the *Spirochæta pallida* (better termed *Treponema pallidum*). The author presents his message in simple, straightforward, yet elegant literary style. It is evident, when reading the preface, that Sir Frederick Treves won fame with his scalpel and not with his pen.

Die Wassermann'sche Reaktion. Mit besonderer Berücksichtigung ihrer klinischen Verwertbarkeit. Von Dr. Harald Boas, Privadozent an der Universität und 1. Assistenzarzt am Rudolph Berghshospital für venerische Krankheiten zu Kopenhagen. Mit einem Vorwort von Geh. Med.-Rat. Prof. A. Wassermann. Preis. M. 5.60. Berlin: S. Karger, 1911.

This volume is an up-to-date treatise on the Wassermann reaction, valuable both as a work of reference and as a working manual. It comprises an historical survey of the subject; the technique which is discussed in great detail; the numerous modifications of the reaction; the various precipitation methods that have been recommended as substitutes for the Wassermann reaction; a discussion of control cases; the significance of the Wassermann reaction in indurations, secondary syphilis, latent syphilis, tabes dodsalis, paralytic dementia, and congenital syphilis; the influence of antiluetic treatment on the reaction, and the relation of prognosis to the presence or absence of the reaction. The wide experience of the author confers a certain degree of authority upon the important conclusions regarding the interpretation of the Wassermann reaction. His attitude is one of careful conservatism. Thus he notes that in congenital syphilis the presence or absence of the reaction affords no definite prognostic criteria. Women who have given birth to syphilitic children react positively without showing any symptoms of syphilis and are to be regarded as cases of latent syphilis. The reaction is stronger in congenital syphilis than in any other forms of the disease. The author emphasizes the important fact that the positive Wassermann reaction is to be regarded as a symptom of syphilis and to be treated accordingly; but its absence has no great prognostic or therapeutic significance. A most comprehensive bibliography concludes the work.

The Diseases of China, including Formosa and Korea. By W. Hamilton Jefferys, A.M., M.D., University of Pennsylvania; Medical Missionary in China; Professor of Surgery St. John's University; Surgeon to St. Luke's Hospital, Shanghai; Editor *China Medical Journal;* and James L. Maxwell, M.D., London; Medical Missionary in Formosa; Chairman China Medical Missionary Association Research Committee. With 5 colored plates, 11 noso-geographical plates, and 360 illustrations in the text. Price, $6.00 net. Philadelphia: P. Blakiston's Son & Co., 1910.

To a certain extent this volume is a treatise on tropical diseases, for the long coastal exposure of China, extending as it does over some twenty degrees of latitude, includes both the subtropical regions and the temperate zone. Of the infectious diseases considered, a long and very complete chapter is devoted to the plague, now invading such a large part of the kingdom. Leprosy and beri-beri also, though not wholly confined to China, are very fully treated. The chapter on the various parasites of the intestinal tract and the blood are especially good. Very few races are so frequently infested with intestinal organisms as the Chinese, the Filipinos being perhaps their only rivals; hence the importance of the subject. The illustrations of the ova and various forms of worms are admirable, a number of them being original photomicrographs. Malaria and filariasis are also frequent diseases in China, and important sections are devoted to a consideration of both conditions. Dysentery, both amebic and bacillary, is frequent in that country and the chapter on the subject is excellent. The rest of the volume does not differ greatly from the ordinary textbooks, except that the subject of vesical calculi is much more fully covered than usual, because such calculi occur with great frequency, especially in the Province of Kwangtung, one surgeon having a record of 1,300 lithotomies. A very excellent section on hospitals and hospital construction completes the work, which should be extremely valuable to physicians practicing in the Far East. The volume is well bound, well printed, and well illustrated.

Über die Bedeutung der Inanition bei Ernährungsstörungen der Säuglinge. Von Professor Ad. Czerny, in Strassburg. Price, 1 mark. Halle a. S.: Carl Marhold, 1911.

In this pamphlet of 24 pages Czerny discusses the significance of inanition in the nutritional disturbances of infancy. He comes to the following conclusions: Infants can tolerate without apparent harm complete or partial inanition for a long time. The danger of death from inanition occurs when, after a gradual loss of bodily substance the total loss amounts to one-third of the body weight. The more rapid the loss the greater is this danger. Inanition resulting from therapeutic measures is of danger in a child that has already suffered considerable losses in weight. Many infants succumb during the course of an infection, not from the latter, but from an accompanying inanition due to other causes.

Der Einfluss geistiger Arbeit auf den Körper unter besonderer Berücksichtigung der Ermüdungserscheinungen. Von W. Bethge, Halle a. S. Price, 1.20 marks. Halle: Carl Marhold, 1910.

This pamphlet is one of those useful little monographs so abundantly produced in Germany, which afford a rapid survey in convenient form of what is being written on any topic. While the title is sufficient to explain the subject matter, attention may be called to an interesting discussion of some of the physical conditions underlying that most popular disease—neurasthenia. The volume is clear in style and contains a useful bibliography.

Society Reports

THE NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Held April 20, 1911.

THE VICE-PRESIDENT, DR. JOSEPH A. BLAKE, IN THE CHAIR.

THIS meeting was held under the auspices of the Section of Medicine.

Recent Advances in Anatomy and Pathology of the Heart from a Clinical and Pathological Point of View.—Dr. ALFRED E. COHN presented this paper. He spoke of the present time as a period of transition in the knowledge of heart disease. Five or six years ago they were concerning themselves with valvular lesions and were devoting their energies to diagnosticating these from the point of view of sounds and murmurs and relatively less from that of dilatation as evidenced in percussion, palpation and transillumination. Now they had come to regard the heart as a whole and to lay more stress on its working muscular portions and less on its automatically acting valves. He did not assume that valvular defects should have a subsidiary place, but called attention to the fact that in their study muscular action as such was a clinical entity from which much valuable information could be gathered. About thirty years ago Englemann and Gaskell placed views of the heart muscle on a more exact basis, so that they had come to speak of them under the headings of irritability, contractility, rhythmicity and conductivity, or the bathmotropic, inotropic, chronotropic and dromotropic functions of heart muscle. They did best to investigate heart muscle and heart disease under these heads, as frequently a patient suffered from a defect of only one of these functions, while another would suffer from a complication of two or more, either as the result of valvular lesion or without any valvular defect. In investigating anatomical facts underlying functions of the heart muscles they had divided them into those which were muscular and those which were nervous. While much had been added to their knowledge of the location of ganglia within the heart, both of man and lower animals, as yet nothing had been added to the knowledge of their function and no clinical abnormality had been correlated with a defect or lesion involving them. Although many facts had been collected in regard to the action of the vagi, accelerators, and the depressor nerves, yet clinical knowledge of them was very deficient, in many respects absent. Practically no investigation existed which related the paths and distribution of the extrinsic with the system of intrinsic cardiac nerves. The study of the muscular architecture of the heart was clinically extremely useful. Great advance was made after Engelmann and Gaskell gave utterance to the doctrine that the propagation of an impulse once formed was conducted to other and appropriate locations in the heart by means of heart muscle and that this function of conduction resided in the muscle. Dr. Cohn gave the history of the finding of the auriculo-ventricular bundle and the node of Tawara and said that the point should be clearly made that no part of this aricular ventricular system should be called embryonic or an embryonic remains. Actually there was known only one series of experiments which had been able to ascribe a definite function to this structure and that was contained in a paper by H. E. Hering in which he maintained that its presence delayed conduction. Aside from the node and bundle, the demonstration of nerve trunks, nerve fibres, and nerve ganglia in the conduction system, and a demonstration of the constant union of the ariculoventricular node with the auricles, completed their anatomical knowledge of the auriculocentricular conduction system. Knowledge about rhythmicity was augmented by the description of a node similar in structure to Tawara's in the wall of the right auricle by Keith and Flack. It began at the junction of the superior vena cava and the upper border of the auricular appendix and extended from there downward a varying distance in the direction of the sulcus terminalis. Structures similar to this were found at other sites. The sino-auricular node had communications with auricular musculature in every direction. That rhythmicity, stimulus production had its seat in this node and acted under normal conditions as pacemaker of the heart was a function originally claimed for it by Keith. Dr. Cohn agreed in this view and also that in it resided the pacemaking function of the auriculoventricular system, through which passed stimuli from the auricles to the ventricles, so maintaining correlated contraction between these two pairs of cavities. Investigations had been confined to conductivity and rhythmicity only, and anatomical explanation for these two only were at hand. Sixty per cent. of all cases of irregularities of the heart fell under the heading of the so-called pulsus irregularis perpetuus. Dr. Cohn related the history of its expansion which he stated was the history of anatomical and physiological advance and reviewed Mackenzie's explanation, which had neglected the doctrine that automatically beating heart portions beat regularly and not irregularly. In 1909 Lewis, Rothberger, and Winterberg demonstrated conclusively that the irregularity was due to auricular fibrillation. Now anatomical interest shifted to a study of the right auricle. Schonberg, Hedinger, and Koch had reported histological studies in this region, while many others were still in progress. In the sino-auricular node, Koch and others had found subendocardial fatty infiltration, small hemorrhages, subacute inflammatory changes, injuries to the nerves and ganglia by connective tissue growth, occasional lesions in the afferent vessels and more or less connective tissue proliferation. Such lesions were designated as sufficient to injure the pace-making function of the node and so induce either fibrillation directly or to remove the controlling influence of the sinus in such fashion as to permit fibrillation to ensue. While these anatomical advances and findings were valuable, interesting and possibly final, enough was not yet known to consider them conclusive, and harm rather than good might result from accepting them now. Thus far isolated lesions involving either the auriculonodal junction or the auriculoventricular node itself were not known. When they considered the main stem a variety of lesions were noted. They might be divided into those which formed complete transverse lesions of the bundle, in the same sense that there were complete transverse lesions of the spinal cord and incomplete transverse lesions. In the group of complete transverse lesions were tumors; metastases or infiltrations; inflammations, which were usually syphilitic; and degeneration due to vascular disturbance, either thrombotic, embolic, or endarteritic. These complete lesions, so far as the author knew, all caused complete auriculoventricular dissociation and might or might not be associated with Adams-Stokes syndrome. In the second group were found the products of chronic inflammation. In the group of incomplete or transverse lesions, cases were found where the auriculoventricular dissociation was complete and others where it was partial. There was a third group of cases in which there were marked lesions of the bundle, but in which, clinically, all types of the heart block were demonstrated, from lengthened A-C intervals to complete dissociation, changing from one form to another in rather startling fashion. There was a fourth group in which heart block had existed clinically for years in which a lesion commensurate with the clinical findings could not be found. Finally there was a fifth group in which one or other of the ventricular branches of the A-V system had been cut off from the main stem. There were a number of other irregularities, also chronotropic functions, expressed in extrasystoles and in tachycardia which had not been considered. Whether chronic

and acute interstitial myocarditis plays a rôle in the production of ventricular extrasystoles was not known. As yet no definite correlation was known between abnormal structure and abnormal function in any of these cases, nor were the limits of structural change in general convertible into the extent of functional deficiency. Much was left to be investigated in the domain of irritability and of contractility of the heart muscle, especially in acute infections and chronic degeneration. In speaking of the instruments employed, Dr. Cohn insisted strongly that these instruments and the curves which they yielded were only a means to an end and unless they could be interpreted from the viewpoint of anatomy and physiology were of comparatively little use.

Methods of Studying the Functional Capacity of the Human Circulation.—Drs. G. Canby Robinson and George Draper presented this communication: It was pointed out that, in order to determine the functional capacity of the cardiovascular system, it was necessary to know the ability of the circulatory apparatus to meet the demands put upon it by increased physiological activities. Blood pressure might aid in this regard when the systolic and diastolic pressures were determined and the pulse rate was taken into consideration. The study of the changes in blood pressure, which accompanied changes in posture, had been of value in the functional diagnosis of the circulation. The charts made from blood pressure and pulse rate records from patients showed definite departures from the normal. Another method used had been the determination of the mode of recovery of the blood pressure and pulse rate after a constant amount of exercise. The blood pressure returned to a state of rest quickly in the normal, the work causing a rise in the systolic blood pressure only, while in abnormal cases, a marked quickening of the pulse was seen in some, and in more severely deranged cases, there might be a marked drop in the systolic and disastolic blood pressure requiring fifteen or twenty minutes to return to normal, as seen in the charts shown. The measuring of the presphygmic period of the heart beat was also described as a diagnostic method. This period was that time between the beginning of ventricular systole and the opening of the aortic valves, and it could be measured by making simultaneous graphic records from the apex beat or from the electrocardiogram and the carotid artery. When the diastolic pressure was known, it could then be calculated how long it required the left ventricle, after it began to contract, to overcome the intra-aortic pressure, and thus some idea of the contracting force of the left ventricle might be gained. The counting of the heart beats which did not cause a pulsation in the carotid artery, the so-called "pulse deficit," had been employed in cases of cardiac irregularity. Records so obtained had been charted, and the number of missed beats could be shown to vary markedly with the use and disuse of rest and drugs, especially digitalis. In order to determine what rôle the peripheral circulation played in any given case, variations in the periphery were produced by a tight abdominal binder, which was shown to have definite influence on the blood pressure and pulse deficit determinations, as well as on the symptoms of some cases.

The Micrograph: An Instrument for Recording Circulatory and Other Physiological Events.—Dr. Albert C. Crehore and Dr. Frank S. Meara presented this instrument and demonstrated its construction and use by means of lantern slides.

SECTION ON MEDICINE.

Stated Meeting, Held February 21, 1911.

Dr. H. S. Patterson, in the Chair.

This evening was devoted to contributions by the medical staff of Lincoln Hospital.

Two Cases of Secondary Pernicious Anemia.—Dr. Nathaniel Read Norton reported these cases. They were young women, aged 20 and 27 years, born in Finland. They had used fish commonly as food, particularly pike, much of which was smoked or dried. They had been in this country about three years and were both employed in the same household as servants. For two years before admission to the hospital the first of these patients had suffered from vague abdominal discomforts and mild diarrhea and for three months she had been weak and pale, had marked dyspnea on slight exertion and severe headaches. There was frequent vomiting, blood being present on one occasion. She appeared to have pernicious anemia. The stools were searched, but no ova were found. The blood picture was typical. There were 1,408,000 red cells, hemoglobin 45 per cent., index 1.60, white cells, 5,000 polymorphonuclears, 30 per cent., lymphocytes, 59 per cent., mononuclears, 10 per cent, eosinophiles, 1 per cent., normoblasts, 3, megaloblasts 3, in 300 cells and the characteristic changes were present in the red cells. She was put on arsenic and iron and at the end of two months left the hospital with the following blood count: Red cells, 4,024,000, hemoglobin, 96 per cent., index 1.24, polymorphonuclears, 40 per cent., lymphocytes, 54 per cent., mononuclears, 1 per cent., eosinophiles, 4 per cent., basophiles, 1 per cent., normoblasts, 2 and megaloblasts 0. About the middle of this course of treatment the normoblasts were 14 and the megaloblasts 16 and at one time there were polymorphonuclears, 20 per cent. to 68 per cent. of lymphocytes, 300 cells having been counted. During this period the second girl entered the hospital with a very similar history, general appearance and blood picture. The ova of *Bothriocephalus latus* were found in the stools. After medication about twenty-three and one-half feet of the parasite were passed, but no head was found. After about six weeks' treatment she left the hospital. At this time there were no ova present, but the blood picture was again becoming worse in spite of her improved general condition. It seemed probable that the parasite was again growing. She received arsenic, as did the first girl, who was induced to return to the hospital. Ova were now found in her stools and after medication 125 feet of parasite were passed. As these parasites were 20 to 35 feet in length, it was probable that there were at least three of them, but no heads were found. These cases illustrated the difficulty of finding the ova or the fact that they were not constantly present. It was interesting to note the contrast in the effect of the arsenic and iron: in the first case, the parasite remaining *in situ*, there was uninterrupted improvement, while in the second case there was but temporary improvement, with but presumptive evidence that the parasite had not been removed.

Dr. H. S. Patterson said he wished to emphasize the work of Talquist in severe anemias due to the *Bothriocephalus latus*. It might be interesting, he thought, to point out the fact that from the decomposing segments of this worm a lipoid substance could be extracted which was capable of producing the picture of bothriocephalus anemia. He had suggested that a similar substance which could be extracted from malignant growths might be responsible for the anemia and cachexia which accompanied malignant diseases. He also had made the suggestion that such an over-production of the lipoid substance by the mucous membrane of the intestine might be responsible for primary cases of anemia. In Germany observers had been able lately to extract from the mucous membrane of the intestine of persons dying from pernicious anemia not more of this lipoid substance than could be obtained from a person dying from other diseases, but more hemolytic.

The Use of Bacterins in the More Violent Forms of Sepsis.—Dr. F. R. Oastler and Dr. B. R. Hoobler gave the results of their work with bacterins in septi-

cemias and chronic pyemias. Of the septicemias there were five groups. Group 1 contained 13 cases of septicemia, five acute and eight chronic, all having their origin in abortions, miscarriages or following labor. Of the five acute cases three died and two recovered. Of the chronic cases two died, five recovered and one was unimproved. The organisms present were streptococcus in seven cases; *Bacillus coli* in two cases; staphylococcus in three cases; pneumococcus in one case. Autogenous vaccines were used in each case. Three of the deaths occurred in less than one week, giving the vaccines no time to produce immunization. The other fatal cases were treated for a longer time without affecting the course of the disease. Group II covered the septicemias following otitis media, mastoiditis and sinus thrombosis. There were five of these cases treated, three acute and two chronic. Four showed streptococcus in the blood and the fifth was caused by the *Staphylococcus aureus.* Four recovered and one died. The fatal case was practically moribund when treatment was begun. Group III included the septicemias associated with appendicitis. There were four cases, all of the chronic type. Two recovered, one died and one was unimproved. The case that died lived but a few hours after the first inoculation. The streptococcus was the infecting organism in each case. Group IV included four cases of malignant endocarditis, in one of which staphylococci were isolated from the blood; in another streptococci and in the other two no organisms were isolated although repeated cultures were taken. Anti-streptococcic serum was used in one of these cases and an autogenous vaccine in the other. Of the two cases which succumbed one received but one inoculation of autogenous vaccine and the other only stock vaccine as no organism could be isolated. Group V comprised the septicemias of various origin, 12 cases, of which five were acute and seven chronic. Five of these cases died and seven recovered. Streptococci were isolated in nine cases; *Staphylococci aureus* in two, and *Bacillus coli* in one case. Of the septicemia cases treated, 58 per cent. recovered. Eliminating those cases which died within a day or two after treatment was begun the percentage of recoveries would have been 71. There were two groups of chronic pyemia cases. Group I included the pyemias accompanying appendicitis. There were two of these cases, both of which recovered. In each the *Bacillus mucosus capsulatus* was isolated. Group II comprised ten cases of pyemia of various origin, mostly accompanying cases of cellulitis, erysipelas, or adenitis. All exhibited metastatic foci removed from the local point of infection. The infecting organism in six of the cases was the *Staphylococcus aureus;* in two other cases the streptococcus was isolated and *Bacillus coli* and *Bacillus mucosus capsulatus* were found in one case each. Two of these cases died. From these results it appeared that 60 per cent. of the cases recovered. Subtracting those cases in which the vaccines did not have sufficient time to produce immunization, the percentage of recoveries would be about 70. Of the fifty cases reported blood cultures were positive in 18. Of those cases having positive blood cultures six died, and 12, or 62 2/3 per cent., recovered. Of those not having positive blood cultures 7 died and 25, or 78 per cent., recovered. The conclusions derived from an analysis of these cases seemed to be: (1) That there was a definite condition of acute septicemia where the treatment by vaccines or in fact by any method was useless, for the patient was so overwhelmed by the toxins that no response to treatment could be obtained. (2) That there was a condition of acute sepsis in which with the aid of proper methods of treatment together with vaccines a large percentage of lives might be saved which would otherwise be lost. (3) That in conditions of pyemia or septicopyemia of a chronic nature bacterins in addition to regular methods of treatment appeared to aid very materially in the recovery of the patient. It was in this variety of sepsis that the greatest benefit seemed to obtain. (4) That there was a class of patients who continued for weeks with a condition of mild sepsis which could not quite be controlled by either the resistance of the patient or ordinary methods of treatment. Here the injection of bacterins would in nearly every case reduce the temperature at once and hasten the recovery of the patient. The injection of bacterins would seem to be indicated, therefore, in all conditions of sepsis; for the dividing line between the first and second class of patients mentioned above was not easy to make and often a patient was helped where treatment had seemed hopeless. No harm had as yet been traced to the use of bacterins and the so-called negative phase had not been demonstrated by writers on the subject. The observation of patients under vaccine treatment showed that localized pus areas often developed in cases of general sepsis, after which the patient recovered, thus leading to the conclusion that bacterins tended to aid nature in changing a general sepsis into a localized process. In the series of cases just reported autogenous vaccines had been used for the most part. These had been obtained by taking cultures from the blood or wound area. Very often it was necessary to take several cultures before a successful result could be obtained and even then failure resulted in many cases. The present dosage had been determined by finding by means of the opsonic index the highest opsonic curve obtainable. This method was crude, but it was the best there was at present. Some experimenters preferred to give small doses frequently repeated, others larger doses every three or four days. All doses should be gradually increased. The effect obtained by the injection of bacterins might be said to consist in an improvement in the temperature, pulse, and general condition of the patient, in improvement in the healing of the wound area, in an increased leucocytosis and a diminished polymorphonuclear count, and, finally, in a fall to normal of leucocytosis and a corresponding rise in the number of red blood cells.

A Serious Infection Involving the Mastoid with Lateral Sinus Thrombosis, Successfully Treated with Vaccines.—Dr. Charles Graef reported this case. The patient was a boy, twelve years old, who had suffered for several weeks with an acute suppurative inflammation of the right middle ear. When Dr. Graef first saw him he showed marked evidences of a severe mastoiditis with urgent need for operation. On opening the mastoid widespread necrosis of the bone with much pus was found. A thorough exenteration of the diseased bone was made. On exposing the lateral sinus pus was seen coming from between the bone and the membranous wall, and this continued for some distance as the course of the sinus was followed until apparently clear territory was reached. The sinus was then opened and found to be free of obstruction and seemingly clean. The wounds were packed in the usual way. The temperature fell to normal within two days after the operation. The patient then complained of tenderness along the tract of the right jugular vein and later in the day severe pain developed in the region of the appendix. An acute appendicitis was immediately operated on by Dr. Putnam; the appendix was filled with pus and on the point of rupture. The child was too ill to be subjected to the added shock entailed by dissecting out the internal jugular vein, although this step was strongly indicated by the signs of a developing thrombosis and the certainty that infection of the blood stream must follow. It was determined to watch for blood infection and make use of vaccines. The pus in the appendix showed the *Bacillus coli communis* only.

On March 17, the day following the appendectomy, a blood culture was taken with negative results. On March 24 streptococci in pure culture were obtained from the blood. Metastatic inflammation had appeared in the right shoulder and elbow, and an abscess developed later on the

dorsum of the right foot. This was opened and from the pus streptococcus in pure culture was obtained. A stock vaccine was obtained, and fifteen millions given subcutaneously. Within twelve hours the temperature dropped from 105.2° Fahr. to normal. On each of the two succeeding days a similar amount of stock vaccine was administered, by which time the autogenous vaccine was ready. This was given in doses of ten millions daily for seven days. The doses were then increased by three million organisms each day until twenty-five millions were being given at a dose. The patient left the hospital fifty-six days after admission. He received altogether twenty-three doses of vaccine, aggregating 413 million organisms.

Suppurative Meningitis Due to an Undetected Fracture at the Base, with Hemorrhages and Infection.—Autopsy.—Dr. Charles Graef reported this case. The patient was a laborer, thirty-two years old. On December 5, 1910, he fell and struck his head; he did not lose consciousness. When admitted to the Lincoln Hospital both eyes showed well-marked ecchymoses. Nothing else was noted except some evidences of shock. He remained in the hospital eight days, slept well and complained of no discomfort. He was discharged seemingly well on December 12. The same evening he was seized with severe chills, fever, and headache. He had a temperature of 105° F., pulse 104, and respirations 28. On December 14 the temperature fell to 100° F. The pulse varied from 60 to 100. There was now noted a conjunctival hemorrhage of the right eye with slight fresh ecchymosis in the left lower lid. The cheeks were flushed, the respirations shallow, and crepitant râles appeared. The pupils were normal. There was some dullness in the right lower lobe.

On December 15 the temperature went to 105° F., the pupils became widely dilated and fixed. The patellar reflexes were exaggerated. He had several severe chills alternating with profuse sweats. Both third nerves were paralyzed, as was the fourth and sixth. Nothing positive was noted in the fundus except a fullness of the veins. There were signs of recent bleeding from the left ear drum. Dr. Graef made a diagnosis of fracture of the base with septic infection of the exudate and blood clot. The patient soon became comatose and died.

At autopsy the inner table of the skull was very noticeably thin and friable. An abundance of pus and fibrin was found in the interpeduncular space; this extended beneath the pons and down the spinal canal. There was a comminuted fracture of the cribriform plate, a fissure extending upward and outward for three and a half inches to the right supraorbital foramen. Another small fissure of the orbital plate of the frontal bone joined these fractures.

A Case of Acute Septic Endocarditis with Autopsy Specimen.—Dr. Leander H. Shearer reported this case, an Italian woman, 28 years of age. She had two children four and six years of age who were in good health. Her previous history was normal save for a mild attack of articular rheumatism two years previous with possible slight cardiac complications. The patient was six months pregnant at the time of the onset of the attack, which was sudden. She was seen by Dr. Shearer on the fifth day of her illness, when she suffered from a violent headache, not localized, and from aphasia. The temperature ranged from 100° to 101.2° F. The heart showed moderate dilatation and moderate enlargement to the left with a well-marked systolic murmur over most of the precordium, most marked at the apex and transmitted to the left. No presystolic murmur was heard. The blood pressure was slightly over 100. The urine was scanty and contained abundant albumin, casts of all kinds, white and red cells. Leucocytes were reported as 10,000; no differential count was made. The uterus was enlarged to about six months size. Fetal movements were distinct and the fetal heart strong and normal. Septic endocarditis was suspected. The blood culture, however, was negative. During the next eight days the temperature gradually ranged higher; there were chills and profuse sweats and the mental condition was excitable and apprehensive. The weakness and frequency of the heart steadily increased and the patient had several sudden and severe attacks of circulatory failure. Two weeks after the onset she was removed to the Lincoln Hospital and during the following week she became markedly jaundiced and her liver was palpable three inches below the free border. Her muscular weakness was extreme and with it she had bilateral increase of the reflexes of her lower extremities with marked ankle clonus but no Babinsky's and no Kernig's signs. The eye reactions were normal. At this time her temperature showed marked excursions ranging from 98° to 105° F. On the twenty-third day of her illness her sputum was blood-tinged and she had considerable pulmonary congestion. Two days later petechial spots appeared and the patient became comatose. She aborted. On the twenty-seventh day of her illness petechiæ were very extensive; the spleen was palpable three inches below the free margin and there were hemorrhages in both conjunctivæ and in both retinæ. She died on the thirtieth day; a blood culture taken that day was negative.

The pathological report, made by Dr. W. G. McCallum, gave as the anatomical diagnosis abortion, placental remains in the uterus, icterus, acute mitral endocarditis with vegetation, acute splenic tumor, anemic infarction of the spleen and kidney. The heart was not enlarged; the surface was smooth; the endocardium on the right side was delicate and likewise the valves. The left auricle was empty except for a large vegetation on the anterior leaflet of the mitral valve. There were small warty vegetations along the lines of closure elsewhere. The main vegetation measured two centimeters in diameter and was very irregular in form. The wall of the left ventricle was somewhat mottled with dark brownish patches. The left lung had three lobes, was bile stained, and the surface was roughened by old adhesions with some fresh exudate and hemorrhages. The lung was tough, flabby, and moist, partly airless but everywhere air-containing. The substance of the right lung was firm and mottled with hemorrhages; some minute patches seemed to be consolidated and in the middle there was a good deal of smooth consolidation. The spleen was much swollen, tense, and discolored There were patches of yellow opacity surrounded by a hemorrhagic zone which projected above the surface. In the middle the spleen was grayish-red; Malphigian bodies and trabeculæ were visible. A pure culture of the staphylococcus was obtained from the vegetation. Specimens of the heart with vegetation on the mitral valves and of anemic infarcts of the kidney and spleen mounted in gelatin were shown.

Two Cases of Osteomyelitis.—Dr. C. H. L. Putnam reported these two cases, which he illustrated by lantern slides.

A Case of Intercostal Diaphragmatic Hernia.—Dr. John C. A. Gerster presented this patient, a longshoreman, thirty-eight years old. He came to the Surgical Clinic of the University and Bellevue Hospital Medical School on December 13, 1910, because of an infected abrasion of the right knee. By chance, a tumor of the left side of his thorax was observed. He stated that three years before he was struck by the end of a plank on the left side of his chest. He did not lose consciousness, but he felt weak. The doctor told him he had a broken rib, but applied no straps. Shortly after the accident he became "black and blue" on the injured side, from the sternum to the vertebral column, and from the clavicle nearly to the pelvis. After the ecchymosis began to fade, he then noticed a tumor of the left side. This never had bothered him. He had noticed no progressive enlargement of the

tumor since its first appearance. At no time had there been hemoptysis, dyspnea, vomiting, colic, or any other untoward symptom.

The man was a well-developed individual and in good general health. The swelling on the left chest wall measured at its maximum 9 in. long, by 7 in. wide, by 4 in. thick. It was situated in the anterior axillary line near the free border of the ribs. It enlarged on coughing. The overlying skin was normal and freely movable. The tumor was painless and entirely reducible through a free gap in the thoracic wall between the eighth and ninth ribs. The opening was 4 centimeters long and 1 centimeter wide and could be closed by the tips of three fingers; its lower end was 4 cm. from the free border, the fingers could penetrate between the ribs to a depth of 2 cm. Reduction occurred with the greatest ease when the patient lay on his right side. In this position the hernia remained absent except upon straining or coughing. It reappeared slightly upon deep inspiration. As soon as any position was taken save that of lying on the right side the hernia promptly reappeared. The percussion note over it was identical with that over the adjacent portions of the abdomen, and was distinct from the pulmonary resonance which was obtained just above its upper margin. Auscultation revealed an absence of vesicular sounds and occasional gurgling intestinal noises. No sounds were heard over the hernia when the patient was drinking. Inflation per rectum had not as yet been attempted, he being an out-patient.

In differentiating between hernia of the lung and intercostal diaphragmatic hernia, the following points were of value: In pneumonia there was retraction on inspiration (if the contents were not adherent); normal pulmonary percussion note; normal breath sounds; and a fine crepitation felt by the fingers when making reduction. In hernia it was possible to obtain a slight bulging upon inspiration (in certain positions), a percussion note identical with that over the abdomen, intestinal borborygmi upon auscultation, and reduction accompanied at times by a gurgle. Upon palpating this hernia, the impression was gained that omentum entered the sac first and formed the superficial portion of its contents, while gut entered afterwards and lay more deeply. What part of the intestine this was could not be determined by ordinary clinical means—probably it was either small intestine or colon in the neighborhood of the splenic flexure.

An Investigation of Recent Outbreaks of Typhoid Fever in an Adirondack Camp and the Discovery of a Typhoid Fever Carrier.—Dr. Charles E. North read this paper. (See page 517.)

Stated Meeting, Held March 21, 1911.

Dr. H. S. Patterson, in the Chair.

A Case of Splenic Anemia Resembling Hodgkin's Disease.—Dr. G. R. Satterlee reported the case of a Russian, twenty-six years old, a shirtmaker. As a boy he had had diphtheria and measles. He denied ever having had any venereal disease. His personal habits were good. He had four brothers and three sisters, all alive and well. There was no hereditary disease. His present illness dated back five years when he had a cervical adenitis with an abscess formation. This was opened at Bellevue Hospital and the condition cleared up. Two years later the cervical and axillary glands began to enlarge; then the patient began to feel sick and generally debilitated. Six months later he was taken to Bellevue Hospital because of hemorrhages from the mouth and nose. Under the administration of arsenic he improved very much. He felt well for a few months when his condition again became bad, and he entered Mt. Sinai Hospital in December, 1909. The left cervical glands were removed and examined; the diagnosis was made of Hodgkin's disease. The Wassermann reaction was negative. The application of the *x*-ray to the cervical and axillary adenitis was followed with good results. This *x*-ray treatment to the spleen was just started when the patient left the hospital. On December 7, 1911, the patient was referred to the University and Bellevue Hospital Dispensary. He then stated that one and a half years ago he began to feel a dragging and heaviness in the left side about the region of the spleen; he could not lie on his left side during the summer. He had a progressive weakness and felt cold most of the time. He had pain in the left side of the abdomen and in the legs. He was dizzy when standing. He had no appetite except in the morning. About fifteen minutes after eating he complained of pain over the stomach. There was no bleeding from the nose or gums. He had no urinary symptoms and his bowels were regular. He was thirsty most of the time, drinking twelve glasses of water during the day. His chief complaint was pain in the region of the spleen and weakness. The patient was very pale and his skin had a dusky hue. The mucous membranes were blanched. There were scabs in the nose and slight bleeding. The lower border of the liver was one and a half inches below the free border of the ribs. The spleen was very large; its edge merged with that of the liver. The edge was smooth, sharp and tender. The major part of the enlargement was dorsal, with flatness to the ninth rib. The red blood cells numbered 2,100,000; the leucocytes 16,000; the percentage of polymorphonuclears was 73 per cent.; the lymphocytes were 15 per cent.; the hemoglobin was 40 per cent. and the color index 0.9; the eosinophiles were 2 per cent. and the myelocytes were 4 per cent. Because of his serious condition the patient was sent to the Washington Heights Hospital where he was kept in bed for two weeks and given sodium cacodylate, one grain hypodermatically three times a day. The patient improved very rapidly and had a very slight rise in the temperature. On December 31 the blood examination showed the red blood cells numbered 3,000,000, 51 per cent. hemoglobin, color index 0.8. The leucocytes numbered 8,000. The macrocytes and microcytes were moderate; the erythocytes were pale and chlorotic and there were but a few normoblasts. The polymorphonuclears were 71 per cent., and lymphocytes 18 per cent., the eosinophiles 9 per cent., and the basophiles 1 per cent. He then was exposed to the *x*-ray over the spleen twice a week. Fowler's solution was given in ascending doses until January 18, when he developed a cough and bronchitis and showed signs of arsenical poisoning; the arsenic was at once discontinued. The cough was very persistent. An *x*-ray picture was taken of his chest and this showed no marked glandular enlargement. An *x*-ray picture of the abdomen confirmed the enlargement of the spleen and liver. On February 3 the red blood cell count showed 3,900,000, and a 69 per cent. hemoglobin. The spleen was eight and a half inches long. By the tenth the cough had improved and the spleen was 10 inches long and moved on change from the prone to the erect position. The changes in the size of the spleen had been noted frequently. On February 27 a persistent diarrhea began, there was also an albuminuria and the patient's condition became much worse. On March 4 he was admitted to the Washington Heights Hospital again. During his stay here the albuminuria increased and he had a rise of temperature every day to about 101 degrees and the anemia increased in spite of the rest and administration of arsenic and he left under protest. At home his condition rapidly became worse and he was taken by ambulance to Bellevue Hospital, where he was at the present time. His condition was very weak but gradualiy improved. The red blood cells numbered 1,000,000 with 25 per cent. of hemoglobin. It was noticed that the course of his illness, the exact diagnosis of which was uncertain, had run in waves, uninfluenced by any particular treatment, not unlike the course of a pernicious anemia. The diagnosis

of a splenic anemia as against Hodgkin's disease was based upon the non-progressive glandular involvement and upon the long-standing enlargement of the liver and spleen. Malignant tumors of these organs were improbable for the same reasons and because any marked improvement in so advanced involvement would also seem improbable. Splenectomy seemed inadvisable. A post-mortem examination only might clear up the diagnosis. Acknowledgment with thanks was due to Dr. L. T. Le Wald for the *x*-ray work and to Dr. John H. Carroll and staff of the Washington Heights Hospital for their aid in following the case and to Dr. Arthur Mandel for the blood examinations.

A Case of Pneumothorax of Long Standing.—Dr. Leander Howard Shearer presented this case. The patient's grandfather and one aunt died of tuberculosis. He never used alcoholics nor tobacco. He denied ever having had any venereal disease. He had had all the diseases of childhood. Otherwise he had always been healthy except for his present illness. In 1908 he had a cough with mucoid expectoration which never contained blood. He had also lancinating pains in the right chest and profuse night sweats. He lost weight and strength. Soon all of these symptoms disappeared except the cough. He always was worse early in the mornings. He was in bed six weeks. That appeared to be the onset of the pneumothorax. He then had an attack of pneumonia. Tubercle bacilli were found in the sputum. An examination of the sputum four months later showed no tubercle bacilli. After his attack of pneumonia the patient went to the country and was apparently well except for a slight cough and some shortness of breath. When the patient returned, December 9, 1909, he had pains in the right chest and a cough. At the dispensary he was told that he had fluid in his chest and he entered the hospital to have it removed. He was a man about thirty years old and moderately well nourished. He had a narrow and asymmetrical chest. There was good expansion of the left chest, but very limited on the right side. There was marked supraclavicular and infraclavicular retraction. An examination of the right chest showed dullness from the apex to the spine of the scapula behind; marked dullness from the apex to the base. The breathing was markedly diminished: there were many fine râles at the base and at the angle of the scapula and at both apices. The heart sounds were of good quality; there were no murmurs nor thrills. The pulse was normal. The knee jerks were exaggerated. There was no Babinski's sign, no ankle clonus, and no Kernig. After aspirating the chest there were found pleuritic râles all over the right chest, with flatness at the base and behind with bronchial voice and breathing. There was marked dullness from the angle up with some resonance at the apex. The râles persisted at the apices. Two quarts of dark yellow purulent fluid were obtained by aspiration. On December 7, 1909, the right chest was aspirated and 2,000 c.c. of cloudy fluid were obtained; this had a specific gravity of 1028. On December 12 it was again aspirated and 1,000 c.c. of turbid fluid were removed: this was thicker than what had been removed before. The Pathological Laboratory report on the fluid removed from the right chest stated that there were no bacteria in the smears for tubercle bacilli; the cultures were sterile. The dates of the tappings and the amounts removed were as follows: December 7, 1909, 2,000 c.c.; December 12, 1,000 c.c.; January 10, 1910, 900 c.c.; August 9, 1,100 c.c.; November 26, 800 c.c.; December 12, 400 c.c.; January 27, 1911 950 c.c. Last August the patient went to the country and gained seven or eight pounds in weight and felt perfectly well. He had returned to his business and later returned to the hospital when he felt that his chest was filling up with fluid again. He now had very little cough and was gaining in weight. The *x*-ray plates taken by Dr. Hirsch were shown.

A Case of Probable Cyst of the Pleura.—Dr. Isaac Ogden Woodruff, Jr., reported this case and gave a lantern slide demonstration of the *x*-ray. The patient was a girl, whose mother had died of tuberculosis. She was fifteen years of age. The interesting findings in the chest were shown on the patient by means of ink markings; in the left upper portion there was an area of dullness, practically flatness, mapped out where there was an absence of both voice and breathing signs. There were absolutely no adventitious signs. There was no increase in the temperature. The patient had been under observation for two months and during this time in the hospital. There was no leucocytosis. The von Pirquet and Wassermann tests were negative. The patient had gained about two pounds in weight during the past two months. The diagnosis had to be made between cyst of the pleura, aneurysm, and new growth.

A Case of Cirrhosis of the Liver, Atrophic; Specific Periostitis of the Femora.—Dr. William Kinnicut Draper reported this case and showed *x*-ray photographs. The patient was a man, a laborer, forty-five years old. He was admitted to the hospital January 25, 1911, and was discharged February 16, 1911. The family history was of no importance, with the exception that they all drank ale. There was no history of cancer or tuberculosis. Occasionally he drank whiskey before breakfast and took ten or twelve beers a day. He used tobacco in moderation. He had had four attacks of gonorrhea. His wife died of tuberculosis. She had had no miscarriages. He had had rheumatism for eight years. His present illness began four days ago, when he was awakened in the night with severe pains in both knees. The joints were not swollen, and the pain seemed to run up the thighs to the hips. He had no other pains. His appetite was good and his bowels regular. There were no symptoms suggesting any pulmonary, cardiac, or renal disease. His chief complaint was of pain in both knees extending up to the hips, most marked in the right and over the lower lumbar vertebræ. He was a well-nourished man. The teeth were carious and there was a marked pyorrhea. The heart was hypertrophied; the sounds were of good quality. The pulse was regular, slow, and the arteries were not thickened. The right knee joint was slightly swollen, tender, and painful. A provisional diagnosis was made of cirrhosis of the liver, subacute rheumatism, mitral insufficiency, and pulmonary tuberculosis. The leucocyte count was not taken; the differential count showed the polymorphonuclears 55 per cent., the small lymphocytes 31 per cent., the large lymphocytes 9 per cent., the transitionals 4 per cent., and the eosinophiles 1 per cent. The patient was placed in bed and given large doses of sodium salicylate with bicarbonate of sodium; this had a marked effect upon the pain and temperature. He complained of much pain in the thighs and there was marked tenderness over both femora. This treatment was stopped on January 19, and he was given potassium iodide. Two days later there were added injections of salicylate of mercury. On February 1 the temperature dropped to normal. On February 3 the count of leucocytes was 6,600; polymorphonuclears, 62 per cent.; small lymphocytes, 34 per cent.; transitionals, 2 per cent., and eosinophiles, 2 per cent. On February 8 the patient was allowed to get out of bed. On February 16 he was discharged. At the time of discharge he was getting 25 grains of the iodide three times a day and the hypodermic injections of the salicylate of mercury, 1/6 grain every other day. There had been no evidences of reaction from the drugs.

Studies of the Leucocytes in Pulmonary Tuberculosis and Pneumonia.—Dr. James A. Miller made a report on these studies and explained Arneth's scheme. This showed the value of it in both the diagnosis and prognosis of tuberculosis. Much work had been done at Bellevue Hospital. Seventy-eight cases of tuberculosis were examined and 315 counts taken; in the cases of pneumonia

173 counts were made. There was no doubt with regard to tuberculosis that they had found something that was definite. Their studies were made in cases of incipient tuberculosis, advanced tuberculosis, far advanced tuberculosis, and in the moribund cases.

The Micrograph—An Instrument that Records the Microscopic Movements of a Diaphragm by Means of Light Interference, and Some Records of Physiological Events Showing the Registration of Sound Waves, Including the Human Voice.—Dr. Albert C. Crehore, Ph.D., and Dr. Frank S. Meara made this demonstration. They said that the interference of light, a physical phenomenon, long used by physicists for the purpose of most accurate measurements, was applied in the construction of this instrument, for the purpose of conveying to the eye or to a photographic film the evidence of and the extent of movements of a diaphragm, comparable to the diaphragm used in the telephone. The instrument contained an air chamber connected by a tube with a tambour such as was used in the ordinary sphygmographic work. This air chamber was closed by a thin metallic diaphragm, on the surface of which was mounted a plane mirror. Parallel with this and separated by an appreciable distance was fixed a plano-convex lens, with the plane surface nearest the reflector. Between these two plane surfaces was produced the phenomenon of interference bands, alternatingly light and dark, and in an instrument of this kind concentrically arranged. These bands were readily seen by looking into the instrument and a lens focused the bands, so that they might be readily photographed. If the diaphragm together with the plane mirror on it moved it approached or receded from the fixed lens and in either case the bands were deflected. This deflection in the concentrically arranged bands caused them to contract if they approached or to expand if they separated. When the tambour was applied to a moving part, as to the radial pulse or apex of the heart, the movements in the part induced changes of pressure in the tube and air chamber and consequently movements in the diaphragm and the bands. It could be demonstrated that the movements of the bands magnified the movements of the diaphragm nearly 50,000 times with the light used, or some twenty times the magnification of the most powertul microscope. It was known that for such degrees of motion as the diaphragm was called upon to perform, the extent of the motion was strictly proportional to the pressure exerted upon it to produce it. A fact of vital significance was that in the instrument the confusing factor of inertia present in the ordinary instruments was overcome. The deflections of the bands were readily photographed and very high periods readily detected, as high as 350 per second in some of their plates. In other words, the instrument recorded sounds with precision, and sounds of the human voice sung into the instrument had been clearly recorded in their work. From the photographic plate moving at known speeds measurements were taken in terms of distance (reduced to time) and of pressure (hands displaced) so that when plotted time-pressure curves were produced and were recognized as the familiar curves of the lever tracings of the sphygmographs in general use. In these curves, however, inertia had been eliminated. The great achievement of the instrument lay in the fact that when the plates were made to move with sufficient rapidity, vibrations of muscle, valves or blood current of several hundred a second might be and actually had been graphically recorded.

Lingual Thyroid; Thyroid Gland in Neck Not Palpable.—Spencer reports the case of a female, aged 23, who had a swelling, first noted by a dental surgeon four months ago. This had caused no appreciable disturbance. It was hemispherical, about 3 cm. in diameter, over the situation of the foramen cecum, and was covered by the normal epithelium.—*Proceedings of the Royal Society of Medicine.*

New Instruments.

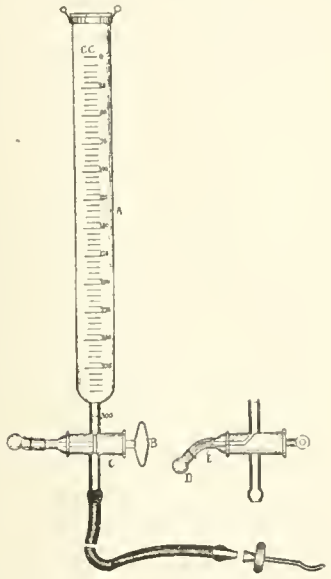
SIMPLIFIED TECHNIQUE FOR THE ADMINISTRATION OF SALVARSAN INTRAVENOUSLY.

By CHARLES H. CHETWOOD, M.D.,

PROFESSOR OF GENITOURINARY SURGERY, NEW YORK POLYCLINIC MEDICAL SCHOOL AND HOSPITAL.

The technique of administering salvarsan by intravenous inection, to be skillfully and rapidly performed, should be simple. If the following directions for making up the solution are carefully observed in connection with the convenient method of administration provided for, any objections or difficulties are removed and the operation is both safe and expeditious.

The apparatus, etc., required are: One tube of salvarsan (0.6 gm.), a small file (provided in each package), one 300 c.c. graduate, one stirring rod, one pipette, 15 per cent. sodium hydroxide solution in glass-stoppered bottle, two flasks of normal salt solution (about 500 c.c. each), one hot and one cold or tepid, special "606" burette (Chetwood), two



sizes of special type of needles, as shown in the illustration.

It is well to have at hand the following additional accessories for special cases: A small amount of sterilized solution of a local anesthetic, 2 per cent. novocaine or cocaine and adrenalin, a hypodermic syringe, a small bistoury, two or three hemostatic clamps, thumb forceps, needle and needle holder, a tube of catgut, a transfusion cannula (seldom necessary).

The essential features to be considered are: (a) A perfectly clear, alkaline solution; (b) avoidance of leakage of salvarsan solution into the tissues when the needle is introduced or withdrawn; (c) a rapid flow of the solution without the introduction of air.

(a) *To Obtain a Clear, Alkaline Solution.*—Pour 250 c.c. of hot, normal salt solution into the sterile glass graduate and deposit upon this solution the entire quantity of salvarsan contained in one tube. A perfectly clear solution is obtained by stirring gently with a sterile, glass rod. By adding slowly from five to ten drops of the sodium hydroxide solution, a turbid mixture results, and by adding ten to twenty drops more very slowly, while stirring

briskly, a perfectly clear solution is again obtained which, when tested with litmus, will be found to be alkaline. This solution is now ready for use.

(b) The leakage of salvarsan solution into the tissues is prevented by being sure that the needle is within the lumen of the vein and has not punctured the opposite wall. The specially designed needle (see illustration) is an aid in entering the vein, and by beginning and ending the injection with a small amount of normal salt solution, any leakage is revealed and no irritation produced thereby.

(c) The free flow of the injection and exclusion of air is accomplished by the use of the simplified apparatus, which also allows of the use of normal salt solution at the beginning and end of the procedure.

After mixing and preparing the solution according to directions, it is well to proceed as follows:

First, pour into the burette (*a*) about 50 c.c. of normal salt solution; turn the stopcock (*b*) to flush out the small outlet (*c*), removing the small cap (*d*). Replace the latter and turn the stopcock (*b*) so as to allow the salt solution to expel the air from the rubber tubing, thereby filling it with a sufficient quantity of saline to start off with. In thus emptying the salt solution the flow should be stopped when it reaches the line marked 300° on the outlet tube (*c*). Next pour into the burette the salvarsan solution in the graduate and add salt solution up to O mark, thereby making 300 c.c. in all.

The skin at the bend of the elbow having been previously prepared and the arm selected in which the veins are more prominent, a rubber tourniquet is applied above the elbow, and when the vein (generally the median basilic) stands out well, thrust the needle into its lumen. The vein has been entered if the blood flows promptly; therefore remove the tourniquet, turn the stopcock of the burette and couple the tube with the needle now in the vein, allowing a little of the fluid to run out while doing so.

If there is no leakage in the tissues the operation proceeds without interruption until the entire quantity is injected, or until such quantity as may be deemed advisable is reached. If a lesser quantity is decided upon, when that quantity is reached the stopcock (*b*) is turned so that the outlet (*c*) is downward, and then, by removal of the cap (*d*), the remaining solution is allowed to run out into the graduate and the small cap returned. Normal salt solution is then promptly poured into the burette, the stopcock (*b*) is turned in the direction to open the flow, and then the salvarsan solution in the tube is evacuated and a small quantity of saline follows it up. Thus the tissues around the vein are not endangered, and the operation is completed satisfactorily by compressing the puncture upon withdrawing the needle and the application of a sterile dressing and bandage.

25 Park Avenue.

Poliomyelitis and Herpes Zoster.—R. P. Garrow notes the wonderful analogy that exists between these diseases, looked at from every point of view, and the fact that they were simultaneously epidemic in a certain district, raises the question, may they not be dependent on the same infective process, attacking the anterior horns of the spinal cord in the one case and the posterior root ganglia in the other? In other words, are not infantile paralysis and shingles one and the same pathological entity?—*British Medical Journal.*

Erysipelas in Babies.—Milhut and H. Stévenin describe two atypical forms of erysipelas that are seen in infants and that are generally fatal in spite of their apparent innocence. The first consists of what appears to be a simple edema which changes its position rapidly. If carefully examined a faint rosy line of demarcation may be found. On the same child may be seen patches of edema, of erythema, and of desquamation. The fever is slight and the general condition little affected. Streptococci may be found in the fluid from the edematous patches, which forms a good culture medium. The second form of erysipelas consists in the formation of a small abscess, which heals after incision, to be followed by a succession of other abscesses in other locations. In infants under three months of age these symptoms almost always result fatally.—*Le Progres Médical.*

Health Reports.—The following cases of and deaths from smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended May 19, 1911.

THE PRESENT STATUS OF INOCULATION THERAPY.*

THE APPLICATION OF OPSONINS AND VACCINES IN THE TREATMENT OF BACTERIAL INFECTIONS, AS TAUGHT BY WRIGHT, AT ST. MARY'S HOSPITAL, LONDON.

BY MARTIN J. SYNNOTT, A.M., M.D.,

MONTCLAIR, N. J.

PEDIATRIST TO ST. VINCENT'S NURSERY AND BABIES' HOSPITAL, MONTCLAIR, N. J.; VISITING SURGEON TO ST. MARY'S HOSPITAL, ORANGE, N. J.; SECRETARY NEW JERSEY STATE PEDIATRIC SOCIETY; EX-PRESIDENT BOARD OF MANAGERS ESSEX COUNTY ISOLATION HOSPITAL; MEMBER ESSEX COUNTY MEDICAL MILK COMMISSION; MEMBER AMERICAN MEDICAL ASSOCIATION, NEW YORK ACADEMY OF MEDICINE, ORANGE MOUNTAIN MEDICAL SOCIETY.

THE publication of Sir Almroth E. Wright's investigations a few years ago marked a new era in the study of the part played by the blood as a protective agent in diseases of bacterial origin. Principles of immunity have been discovered by him which have thrown new light upon problems hitherto obscure, and scientific inquiries have been stimulated along lines destined to produce results of great importance in the domain of practical medicine.

The value of Wright's vaccines in the treatment of various infections is now generally conceded by scientific men. If it is true that by means of bacterial inoculations we have the power of raising the antibacterial power of the blood, we must all admit that Wright has really given us "the most valuable asset in medicine," and that his discovery of means of successfully combating infectious microorganisms merits to be regarded as the greatest achievement of curative science and one of unrivaled importance to the world at large.

Wright's success in the treatment of bacterial diseases by means of specific inoculations has been such that the system of therapeutics elaborated by him is now accorded a prominent place in medical literature, and practitioners are rapidly coming to a recognition of its merits.

The result has been that a pilgrimage of scientific men, larger each year, has been wending its way to St. Mary's Hospital, situated in the Paddington District of London, England, because it is here that Wright pursued his scientific studies, holds his clinics, and has established well equipped wards and laboratories for experimental, instructional, and research work. This hospital, which was founded in 1841, has its own medical school attached, and provides accommodation for 350 beds.

"The Department of Therapeutic Inoculation" was instituted at St. Mary's Hospital by Wright in the fall of 1905. The method of vaccine treatment had prior to this been gradually perfected by him in the pathological laboratory of the hospital, and the treatment of patients by this method had been carried out for three years in the Pathological Department. The results of treatment had thus been under the observation of the hospital staff for several years before the establishment in 1905 of a separate Inoculation Department.

The staff of the new department consisted at the outset of a director, Sir Almroth E. Wright, and two permanent assistants, Captain S. R. Douglas, and Dr. J. Freeman. A third permanent assistant was shortly found to be necessary and Mr. J. H. Wells was appointed to this position. Further enlargement of the staff has been made from time to time, and Mr. John C. Matthews, Mr. A. Fleming, Mr. W. Parry-Morgan, and others have been added at the discretion of the director to meet the increased work of the department. These are all paid assistants and are men of experience and skill in this special work. Numerous scientific articles on bacterin therapy and opsonotherapy have been published by these gentlemen, recording the results of original research, and adding valuable material to the literature on this new science. Temporary assistants and volunteer associates have also been appointed, many of whom came originally to St. Mary's as students.

Teaching work began in 1906, and a systematic course of instruction has been gradually elaborated by the staff of the department in the principles and practice of therapeutic inoculation. This includes lectures and demonstrations and also personal laboratory instruction to the many hundreds of men who have come to the hospital desiring to learn the technique and to qualify themselves for carrying out the treatment. More than a score of different countries have been represented in this number. The methods of treatment by inoculation which originated at St. Mary's have thus been carried throughout the world, and the propaganda has spread rapidly.

Several of the men who have matriculated at St. Mary's, after remaining for various periods as paid or voluntary assistants, have since returned to their homes and are now engaged in teaching. Among the earliest of these was Dr. G. W. Ross, who has inaugurated a "Department of Immunization and Medical Research," in connection with the Toronto General Hospital, in Toronto, Canada, where an instructional laboratory is now conducted under his supervision.

The work of the new department at St. Mary's grew so rapidly and the number of patients increased to such an extent, that it soon outgrew its original quarters in the museum of the hospital, which were found to be too small and otherwise inconvenient. Accordingly the department was transferred in 1909 to the new building known as

*Read before the Orange Mountain Medical Society, March 17, 1911, at Orange, N. J.

"The Clarence Wing," erected as a memorial to the deceased brother of the present King of England, where it occupies spacious quarters on three floors. This building, which is a modern, fireproof structure, provides a separate entrance from the street to the Inoculation Department and the arrangements are ideal for the purposes to which it is now applied.

Recently the long sought after desideratum was obtained and five wards, providing beds for 31 patients, have been equipped for the treatment of inpatients directly by the staff of the Inoculation Department. This has made possible the further prosecution and extension of the research work, besides enlarging the usefulness of the department. It has made it feasible to receive and treat many patients who were suitable cases for benefit from inoculations but whom it would be impossible to treat as out-patients. It also makes possible the continuous, accurate, scientific, and methodical observation of patients which is so desirable and necessary in many instances. The other departments of the hospital are in thorough accord with the Inoculation Department, and ready cooperation is always extended.

While the majority of the men who "take out" the course at St. Mary's are trained laboratory workers and bacteriologists, including professors and teachers, previous laboratory experience is not essential, although it gives one a great advantage. Several men have taken the course successfully who had almost no previous knowledge of the blood, bacteriology, or even of the microscope. A trained laboratory worker may acquire the technique, if he devotes all of his time to it, in one month. The laboratories are always open and the student may work as late at night as he chooses. Three months is a safer time to count upon, and many men spend a year or more and still feel they have much to learn. One may stay on as long as he wishes, and if he shows proficiency may secure an assistant's position with a salary of $500.00 per annum. Each matriculant is required to pay a fee of 10 guineas, (fifty dollars), for the course of instruction.

Sir Almroth has his own desk in the research laboratory, but does no teaching except at the Tuesday and Friday afternoon clinics. He is at the hospital daily, except during his holiday season in August, and is reasonably accessible. These public clinics are open to the medical profession, no fee being charged. An intelligent observer may learn much at these clinics concerning dosage, frequency of inoculations, indications for vaccine therapy, mode of administration, and the class of cases most benefited. They are given as a rule by Wright himself. In his absence they are conducted by his associate, Captain Douglas.

Even a sceptical observer will I think soon become convinced of the value of vaccines in bacterial infections from watching for several weeks the patients who return for regular treatments to these clinics. The results in many cases are so brilliant and striking that one can scarcely refrain from enthusiasm.

In addition to the laboratory work the student is expected to attend these bi-weekly clinics and an opportunity is afforded the advanced ones to assist in the examination and treatment of the patients. The regular paid assistants are engaged more or less constantly in research work, and the student may, if he is *persona grata* in the laboratories, keep in touch with what is being done, and learn much in other lines than opsonic estimation, if he so desires.

It will aid the matriculant at St. Mary's materially and save him time in arriving at an intelligent understanding of the work, if he first familiarizes himself with certain acknowledged facts and basic principles underlying the theory of opsonins and vaccine therapy. A brief résumé of the scientific investigations leading up to Wright's discoveries is therefore given, and in presenting it the writer has endeavored to make it conform to the teaching enunciated at St. Mary's.

Immunity.—Science teaches us that we live immersed in a sea of minute life—that microorganisms are all around and upon and within us—that they are to be found in the air we breathe and in the water we drink; and while some are possibly beneficial to us, others are our deadly enemies. It has further convinced us that all infectious diseases are caused by specific microbes, and that there are few diseases which are not either originally caused or at some later period in their course aggravated by their presence. These facts have been definitely proven by laboratory research and experiment. Gradually the list of infectious diseases that have actually been so traced has swelled, and no one doubts that it is due only to our imperfect methods of investigation that the list does not include all.

In the past our attempts to combat infection have been directed against microorganisms outside the body, by hygiene and health measures for the prevention of epidemics, and antisepsis in surgery. But of late, as a result of newly acquired knowledge, Wright has taught us that it is possible to engage in an active defense against these unseen enemies, pathogenic bacteria, by the stimulation of immunizing agencies within the body.

The blood is the true environment of all the cells of which the body is composed, and it is here that both the attack and the defense in the war with microorganisms must begin. The blood supplies life to the organism and the means of complete intercommunication. When an infectious microbe once gets access to the blood stream the way is open to every cell. In this the blood circulation differs from the secondary and more sluggish lymph circulation, where Nature seems able to set up barricades in the form of glands to arrest and partially cut off intercommunication.

When once a microorganism has gotten into the blood stream the surroundings there are almost ideally fitted for its growth. Our laboratory knowledge teaches us how well many bacteria thrive on the blood fluids, and therefore the conclusion must be apparent to every one that, but for some hidden cause, the rich nourishment that is on its way to feed the specialized cells of the body would be an admirable nidus for them, and result in their almost infinite multiplication.

There is no explanation of the phenomenon of recovery in infectious disease other than that the infected system develops a resistance to the action of the invading pathogenic microbes which it did not originally possess, and that complete recovery is due to this resistance becoming strong enough to overcome and destroy the microbe. Furthermore we now know this change in the system of the individual who is attacked by the disease continues for a longer or shorter period after the disease has run its course. A convalescent from an infectious disease is ordinarily in no danger of

taking it afresh. This non-liability to take the disease a second time is known by the term "immunity," and it is under this title that the problem of the development of such resisting agencies has usually been studied. One great result of the investigations of Wright and others has been to enable

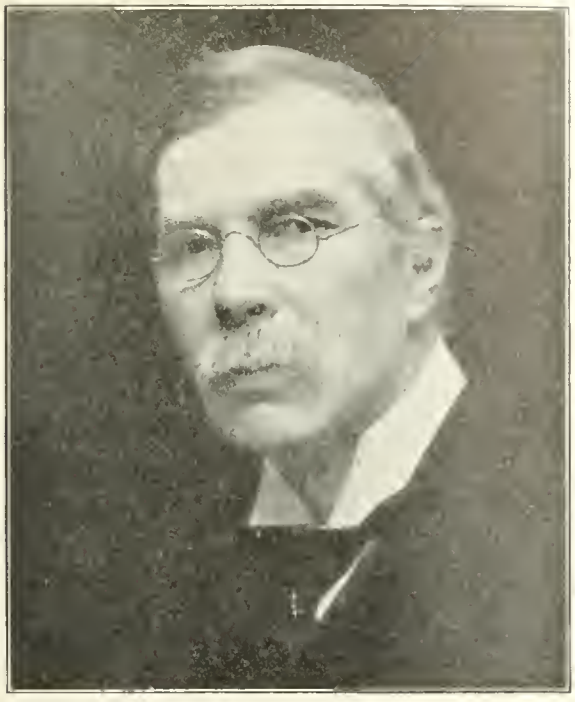

Fig. 1.—Sir Almroth E. Wright.

us to prevent individuals from contracting certain diseases by creating in advance this state of resistance, which ordinarily manifests itself only in the presence of the disease itself, or after the patient has recovered from it. By immunity we mean not only the non-susceptibility of an individual to a given disease and the power to resist infection, but also the mechanism by which a cure is effected. There is no such thing as absolute immunity to a given disease, because, provided the dose is large enough, the disease will be contracted.

Immunity is divided into two heads:—(1) Natural immunity or the immunity which a man possesses of himself; (2) Acquired immunity, which may be either (*a*) the immunity acquired from a previous attack of the disease, as in smallpox, typhoid, or scarlet fever, or (*b*), artificially acquired immunity. The mechanism of the process is the same in each.

Artificially acquired immunity may be *active* or *passive*. *Active immunity* may be secured in many various ways, but in this paper we are concerned only with Wright's method of producng immunizing or protective substances in the blood by injecting into the patient devitalized bacteria. This is called *vaccine* or *inoculation therapy*.

Wright discovered early in his investigations that the injection of bacteria or their products into a patient causes the body to elaborate protective substances in response to the stimulus.

It is not possible to use active immunization successfully in the treatment of every acute disease because the protective substances are slowly produced. Fortunately in several of such exceptions we are able to resort to *passive immunity*. In this it is first necessary to immunize an animal actively and then, when the protective substances are produced, the animal is bled and its serum is used for curative purposes on the person attacked by the disease for which the serum was produced. This is known as *serum therapy*. In other words in the case of a serum we first inject the bacteria or their products into the body of an animal, and, after the latter has elaborated the proper amount of protective substances, we inject these latter ready made into the patient we are treating. By this method we give our patient in a serum form the remedy of Nature, replete with protective substances. Passive immunization is the ideal one of course, but it has up to the present time been found impossible to produce such sera from known bacteria except in diphtheria, tetanus, epidemic cerebrospinal meningitis, hydrophobia, and dysentery.

Diphtheria antitoxin is prepared by first producing a powerful diphtheria toxin, and separating it from its bacilli by passing it through a filter which filters out the bacteria but not the toxin. The filtrate is standardized and is then used to inject into a horse, starting with a small dose and gradually increasing. When the horse has produced enough antitoxin, it is bled, and the serum thus obtained from this immune animal is measured and standardized. This serum contains the antitoxin and is used to produce passive immunity in man.

Wright has demonstrated that when we administer an antitoxin we are merely introducing into the body an increased formation of some substances which are already present in the blood. According to this hypothesis antitoxins of great variety are normally present in the body in small quantities, ready against the enormous number of toxins of various kinds which may attack them.

The first practical application of active immunity was made by Pasteur, in an attempt to protect sheep from the deadly anthrax. He hit on the

Fig. 2.—Captain S. R. Douglas, I.M.S.

idea of inoculating sheep with an attenuated strain of anthrax microbes. This left a state which, though they could not wholly resist a virulent inoculation, enabled them to bear such an inoculation

without serious disturbance, and thereafter they were found to be immune for a considerable time.

The field for active immunization by the injection of bacterial vaccines is much wider than that of passive immunization with antitoxic sera.

The sole service which a serum renders is to

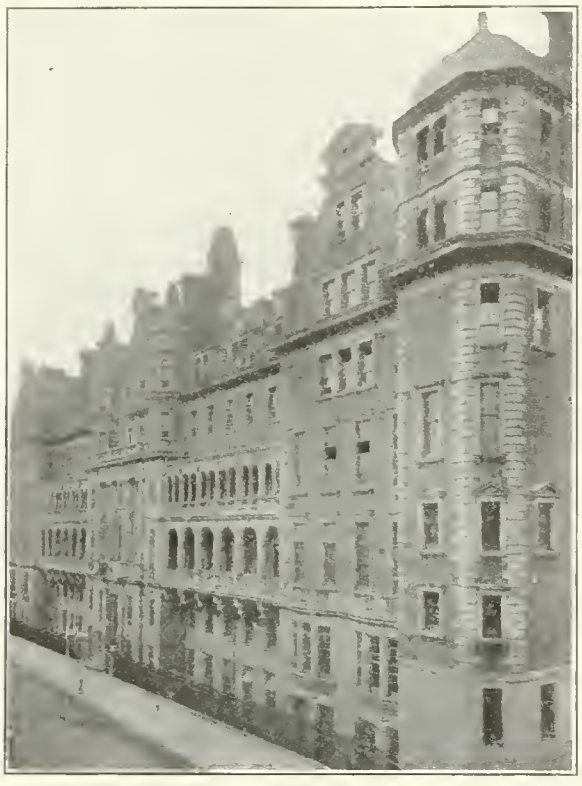

Fig. 3.—St. Mary's Hospital, Clarence Memorial Wing. The inoculation department occupies the first three floors on the right end of this building.

neutralize the poison. There is no ground for thinking that it affects the microbes themselves—indeed, they can readily be cultivated in it. If they are got rid of, it must be by other agencies. Wright's hypothesis deals with the agencies that get rid of the invaders themselves. In the serum treatment we are concerned for the most part with "exoteric" microorganisms, of which the Klebs-Loeffler is a type. Such bacteria produce toxins from the media in which they grow. The toxins are very easily diffused throughout the body and produce the clinical symptoms of the disease.

In vaccine therapy on the other hand we deal for the most part with bacteria which produce the poisonous substances within themselves, and these we call "endotoxins," types of this class being the streptococcus and the staphylococcus. The endotoxins are set free in the body only by the death and disintegration of the bacteria, and are not diffused by the blood stream as in the case of true toxins.

In the exoteric bacteria the chief danger to the patient is from the toxins produced by the invading microorganism. The antitoxin neutralizes such toxins after they are absorbed by the tissues and are diffused throughout the body, and serum treatment is ideally suited to such infections.

The majority of bacteria, however, produce their poisonous substances for the most part within themselves; and to overcome these endotoxins serum treatment has, as we would expect, for the most part proved a failure. To combat the endotoxins we must attack the invading microbes themselves, and this we are enabled by Wright to do successfully with vaccine inoculations.

Wright has demonstrated that when a bacterial poison is introduced into the human system the protective mechanism of the body is stimulated to activity by the attack, and there is at once formed in the blood an antibody or antidote to the particular microorganism causing the infection. In other words the poison that is introduced starts the manufacture of its own antidote. The most characteristic feature of this phenomenon is that the remedy thus produced is specific and is against no other infection except the one involved in the disease in question. Thus the diphtheria antitoxin has no effect except to neutralize the diphtheria toxin.

In infections the danger wholly consists in the quantity and virulence of the invading microorganisms, and the damage done before they can be overmastered by Nature's immunizing defences. This demonstrates the necessity for prompt and early intervention if vaccines or sera are to be used successfully in acute diseases.

The nature of antitoxic action is purely a chemical reaction, the toxins being neutralized by the antitoxins. The inoculation of a patient with a serum merely helps nature temporarily by neutralizing the poison of the disease until the natural agencies of the body have had time to get the better of and destroy the invading microbes. In acute virulent diseases such as diphtheria and tetanus, where the toxin is so powerful and so rapidly generated that it constitutes the main danger, we may thus gain for Nature the time necessary for increasing her defensive forces by introducing supplies of the antidote which she herself might have generated abundantly under more favorable circumstances. In other words when we administer a serum we endeavor to supply an antidote from outside the body which will protect the system until the attack is over or until the organism is in a position adequately to defend itself.

It would seem probable that the injection of an antitoxin does not substantially accelerate the moment when the system is able to deal with the microbes, but it prevents the occurrence of serious

Fig. 4.—Instructional Laboratory, Opsonic Department, St. Mary's Hospital.

organic lesions during the period of conflict, and thus indirectly ensures the victory over the invaders. For the reasons given above, the number of diseases to which serum treatment will prove to be applicable is likely to remain small, however striking its success may be in the cases

where it can be used. Thus, both its aim and the scientific basis on which it rests distinguish it completely from Wright's plan of inducing active immunity by therapeutic inoculation.

To summarize we may say that active immunity is the immunity induced by the elaboration of specific immune substances in the organism to be immunized; whereas passive immunity is the immunity induced by the introduction of immune substances formed in the tissues of a like or unlike species. Both active and passive immunity have been used successfully as prophylactic measures to produce acquired immunity.

Phagocytosis.—The agencies of resistance called into play within the human organism by the inroad of the microbes of a disease are numerous. But the most important is beyond question the action of the white corpuscles of the blood in taking the invading microbes into their substance and ultimately digesting them. This process is known as "phagocytosis."

The duty of the white corpuscles has been demonstrated to be to arrest foreign bodies that make their entrance into the body and either to prevent their gaining access into the blood or to remove them from it. On the introduction of foreign bodies—such as bacteria—into the anatomy, there usually ensues a flow of lymph to the spot, which is quickly followed by an incursion of large numbers of these white blood corpuscles which seize upon the bacteria, and ultimately though slowly digest them. If the number or activity of these corpuscles is sufficient the infection is suppressed, but if from the number of the bacteria inoculated or the rapidity of their multiplication they are too much for the white blood corpuscles to destroy, they establish their footing, and an infection ensues which may remain local or may become general according to the circumstances of the case and the nature of the bacteria.

Therapeutic inoculation rests upon the experimental fact that this phagocytic action can be stimulated by the hypodermic injection of killed cultures of the microbe into the tissues of a patient while he is suffering from the very disease which that living microbe causes. Such inoculation is found to increase the avidity with which the white corpuscles of the blood devour the microbes and thus to bring about the turn of the tide of battle which we call recovery. The curative results thus obtained show how powerful an agent for good is this stimulation of phagocytosis, and how fully justified Wright was in assigning to phagocytosis a chief place among the agencies by which Nature resists the attacks of microbic diseases.

Opsonins.—Wright has demonstrated by very simple but convincing experiments that the leucocytes are not capable of phagocytosis except in the presence of the blood serum, and has clearly proven that the bacteria must first be prepared for phagocytosis by something in the serum; in other words that there are substances in the blood fluids which must modify the bacteria in some way before they are ready for phagocytosis.

The term "opsonins" was coined by Wright and Douglas to designate these substances in the blood serum. The word is derived from the Greek verb, *opsono*, I cater for, I prepare victuals for. The action of the blood fluid in preparing the bacteria for ingestion by the leucocytes Wright calls an "opsonic effect" and the elements in the blood serum which produce this effect he calls the "opsonins." Opsonins may therefore be defined as protective substances in the blood serum not yet isolated, but known to exist there, whose function it is to unite with bacteria and prepare them for the leucocytes to attack and destroy. Without such preparation the leucocytes are unable to ingest bacteria, and this defensive power of the organism is in abeyance.

The Opsonic Index.—The opsonic index is the expression of the measure of the phagocytic power produced in a sample of washed leucocytes by the serum of the individual in question, as compared with the phagocytic power induced in a similar sample of leucocytes by the serum of one or more healthy individuals. In other words it is the result of a mathematical calculation following a technique devised by Wright to estimate the quantity of opsonins in any blood we desire to examine. Such determinations and observations are of great scientific value and of practical utility in determining the dosage, limitations, and contraindications of vaccine inoculations; and as an aid to diagnosis in obscure infections.

The opsonic index of an individual is expressed as a fraction of unity, above or below, according to the greater or less quantity of substances in the infected serum, as compared with the normal serum. The opsonic index then is the measure of the resisting power, as comprised in phagocytosis, of a patient's serum, against the microbe in question. Thus if we say that a patient has an opsonic index of 0.5 to the tubercle bacillus, we mean that his blood contains but one-half the normal quantity of those opsonins which are essential to combating the infection of the tubercle bacillus.

The technique devised by Wright for the estimation of the opsonic index is difficult to acquire and much patient endeavor and practice are necessary before one is able to secure trustworthy and satisfactory results. It requires the highest perfection of laboratory investigation, combined with painstaking application, and conscientious attention to details—in short absolutely faultless technique. No matter how expert a pathologist or bacteriologist a man may be, he cannot become an opsonist by looking over the shoulder of one of Wright's assistants in the laboratory at St. Mary's for half an hour as part of an afternoon's summer holiday in London. Some have tried to do this, and thus are explained many failures, and to this fact may be attributed much of the wholly unjust criticism and reports of anomalous and contradictory conclusions heard occasionally in medical gatherings about New York. The *reductio ad absurdum* of men who do not fully understand what they are talking about, when they report failures at home, is of no value and should not discourage any earnest man from undertaking the work. An indispensable essential if the opsonic estimations are to be at all reliable is that they must be conducted according to a uniform and suitable system of technique. In so complex a subject accuracy is most important and this can be secured only by skilled workers who follow the same method. This further explains why the results in this country have not been more satisfactory. It is a fact that we have in the United States only a very few laboratory workers who really understand the opsonic technique as carried on at St. Mary's.

It is essential also that the normal phagocytic count and the patient's phagocytic count be made

by the same opsonist, in order to reduce the percentage of error. No two men count exactly alike, but if the same man makes both counts the percentage of error is the same in each, and hence the resultant opsonic index is not materially influenced.

Vaccines.—A vaccine, as prepared at St. Mary's,

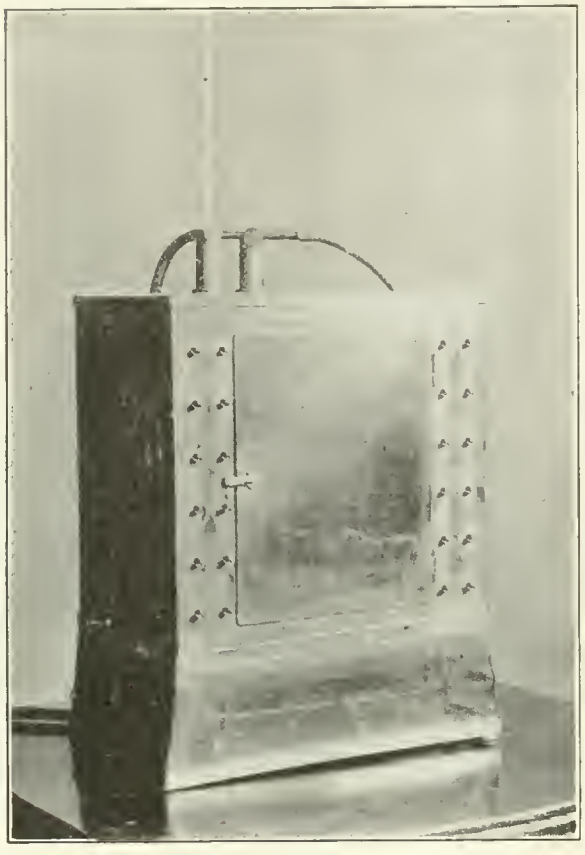

Fig. 5.—Combined opsonizer and incubator.

is a standardized suspension of bacteria in physiological salt solution, preserved in 0.25 per cent. lysol, or in 0.5 per cent. carbolic acid, in which the bacteria have been killed by immersion in water in a water bath at 60° C. for one hour. The vaccines are bottled under the most perfect aseptic precautions, and the bottles closed with a rubber cap, the latter coated with melted paraffin wax. In use, a drop of pure lysol is placed on the rubber cup, and the sterile needle of a hypodermic syringe is plunged through the center of this drop into the bottle and the amount needed for the dose withdrawn. Thus danger of contaminating the contents of the bottle is eliminated. Single doses of certain vaccines are also put up in sealed glass capsules.

The vaccine is administered by hypodermic injection; in men the injection being made through the skin of the abdomen and in women in some fleshy portion of the chest, shoulder, or arm. A drop of pure lysol is placed on the site selected for the inoculation and the needle is forced into the skin through the center of this drop of lysol. No other preparation or cleansing of the skin is necessary. After the injection the lysol is wiped off the skin with absorbent cotton and alcohol. There is little or no local reaction or inflammation ordinarily from the inoculation.

For rapid sterilization of hypodermic needles, syringes, etc., Wright has devised a special oil sterilizer, a cut of which is shown herewith. This is a very clever and satisfactory device and is a great time-saver, particularly in the clinic, because successive inoculations may be given with the same needle and syringe without danger of infection to the patients. Wright observed that olive oil will heat quickly over a small ordinary gas jet to a temperature above 150° C. without boiling. This high degree of heat—one and a half times the boiling point of water—gives almost instant sterilization to any object immersed in it. After each inoculation the hypodermic needle is dipped in the oil for a few seconds and the hot oil drawn up into the barrel of the syringe and forced out, after which the syringe is absolutely sterile and ready for use on the next patient.

The vaccines are standardized, each c.c. containing definite numbers of microorganisms, so that the dose may be easily calculated.

Many immunizators have attempted modifications of Wright's technique in the preparation of vaccines. All agree that it is important to kill the bacteria with the minimum exposure and degree of heat. The German school prefers to kill the bacteria by chemical means and without exposure to heat, claiming the advantage for their method that the vaccines are more potent and retain their efficiency for a longer period. Dr. Ross of Toronto is now preparing his vaccines in this way.

In order to determine upon the appropriate vaccine for a given case we must first decide what microorganism is the cause of the disease under investigation. In many instances this will be apparent from the nature of the disease itself. Thus in the case of a boil it is a fairly safe conclusion that the trouble is caused by the staphylococcus. This same microorganism is associated with carbuncles, osteomyeltis, sycosis barbæ, suppurating acne, and often with eczema, whitlow, and occasionally infectious endocarditis. The streptococcus on the other hand is associated with most forms of infectious cellulitis, lymphangitis, puerperal septicemia, septic endocarditis, and erysipelas; the tubercle bacillus with many joint, glandular, and osseous swellings, many skin lesions, tuberculous peritonitis, and frequently in infections of the genitourinary system. Thus it may be possible for the practitioner to determine the probable causal microbe, and to select an appropriate vaccine, from the clinical picture and symptoms without precise bacteriological procedure. This is an elementary factor in the bacteriology of vaccine therapy, and

Fig. 6.—Method of filling hypodermic syringe through a rubber-capped bottle.

the recognition of the fact that many common lesions are always associated with certain microorganisms will materially aid the beginner to a solution of many initial problems of vaccine therapy.

It frequently happens, however, that the diagnosis cannot be determined without recourse to laboratory methods. In cases of this kind any discharge from the affected part of the organism itself either may be directly examined by an ordinary smear preparation, stained by a simple basic stain, or by Gram's method; or if more than one organism be present, we must grow them in the laboratory until pure cultures are obtained.

It is most important before starting inoculations to be sure of our diagnosis and to exclude the possibility of error in the identification of the microorganism causing the infection. The success of the treatment depends upon this precaution. Absolute certainty is crucial, because microbes are indifferent to anything not directed specifically against them.

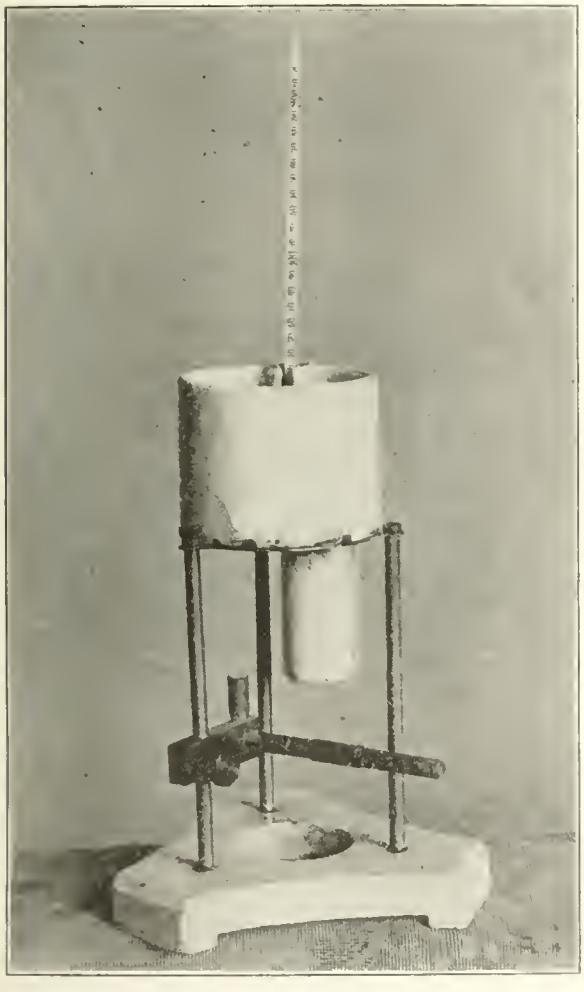

FIG. 7.—Wright's oil sterilizer.

This fact is well illustrated by a case in which the patient was suffering from tuberculous glands. Treatment with tubercle inoculations healed them completely with the exception of one, which continued unaffected until at last it commenced to suppurate. It was then found that the failure to respond to treatment was due to the presence of streptococci in that particular gland. Cultures were made of it, and inoculations given of these cultures with the result that this gland also healed when the treatment was specifically adapted to it, though it had been utterly unaffected by the previous tubercle inoculations. One must bear this in mind and if in treating an infection due to a particular organism we find good resistance to that organism as shown by the opsonic index, without improvement in the patient's condition, we must not overlook the possibility of the patient having also some other infection, in which case we may have a progressively high index to the first organism but the clinical aspect of the case will not correspond, because of the complicating disease. For example take a case of pulmonary phthisis showing a good index to the tubercle bacillus yet the patient may die because of a complicating streptococcus infection. In this way many contradictory reports of inexperienced workers are explained.

The technique involved in Wright's method of preparing vaccines as well as in the determination of the opsonic index is part of the regular course of instruction at St. Mary's. It is very essential for the future immunizator to understand thoroughly every step of the process, particularly the accurate standardization of the vaccines, because, as will be seen later, correct dosage is most important for successful therapeutic inoculation.

The Positive and Negative Phase.—Following a bacterial inoculation there is usually a drop in the opsonic index of the patient, accompanied by characteristic clinical symptoms. This is the so-called "negative phase." The length of this phase and the clinical symptoms depend upon the size of the dose. If the dose has been correct the negative phase seldom lasts longer than 24 hours. The clinical symptoms may be either subjective or objective or both; the subjective symptoms may include one or all of the following: general malaise, a "seedy" feeling, increased tenderness and pain at the site of the lesion, or in the limbs or joints, lassitude, headache, nervous irritability, drowsiness, and in bladder cases increased frequency of micturition; the objective symptoms ordinarily observed are an increase of the discharge, swelling, or congestion, in cases of acne an increase in the number of foci of infection, and in bladder cases perhaps more cloudiness due to increased activity of the infective microbe. There may occasionally be a slight rise of temperature. An abrupt drop in the temperature from 103° or 104° F. to subnormal may indicate an excessive dose. Occasionally rigors, high temperature, and vomiting may follow an excessive dose. Or the clinical symptoms may be absent altogether, depending on whether the dose has been excessive, moderate, or small.

This state is then followed by a rise in the opsonic index, indicating an increase in the opsonic value of the blood, providing the patient has the power to react. Clinical evidences of improvement are also apparent. A state of general invigoration ensues which is quite marked. The patient feels better and very gleefully says so. The rise in the opsonic index following the negative phase Wright calls the "flow"; the subsequent decline in the index toward normal he designates as "the ebb"; the two together constituting the "positive phase." It is when the ebb becomes manifest that the inoculation is repeated.

If the patient has lost the power to react to the stimulus of inoculation, a vaccine, except perhaps in minimal dosage, may so lower the resisting power of the blood that a continued negative phase may be induced and serious, even fatal, results ensue.

Theoretically we should aim so to regulate our dose as to secure a prolonged positive phase without any negative phase, but in practice this is found to be impossible and clinical experience teaches us that after a moderate negative phase we secure a longer period of increased immunity. Unless the

positive phase is preceded by a negative phase it will be of very short duration. The best results are obtained therefore where a negative phase, giving at the most only mild subjective symptoms and lasting not longer than 24 hours, is followed by a positive phase lasting from 3 to 10 days. Such a result when the index is charted is designated by opsonists as the "ideal curve." This dictum applies to all cases except general infections with fever when bacteria are present in the blood stream. In such cases even a very brief negative phase may do harm and if vaccines are to be used at all, they should be given in minimal doses, at more frequent intervals perhaps, but always controlled by the opsonic index. When our methods become more perfect and exact it may be possible to so determine our dosage as to avoid the negative phase. A moderate negative phase in localized infections can do no harm, because the opsonic content of the by-circulating blood does not immediately affect the disease focus.

While it is true as stated above that within certain limits experience teaches us that the longer the negative phase the longer the positive phase will be, this holds true only up to a certain point, beyond which any attempt to lengthen the positive phase by increased dosage results in a dangerously prolonged negative phase and lowered resistance, and ultimately no positive phase accrues at all.

Our aim should be so to gauge the dose and interval that symptoms of improvement, as evidenced by the index and clinically, exist with as little as possible negative-phase interruption. To accomplish this result, the successful immunizator must be able not only to call to his aid the opsonic index, but also to understand how to interpret correctly the clinical signs. Neither is a safe guide alone. Upon these considerations depends the solution of all problems concerning dosage and frequency of inoculations. We must remember that our object in administering vaccines is to raise the opsonic power of the blood, and this we do if the vaccine is appropriate, the dosage accurate, and the reinoculations at proper intervals. In this way a more or less continuously elevated opsonic power may be produced and a cure result.

The indication for a reinoculation as already stated is a fall in the opsonic index to or below normal. When the opsonic index shows after subsequent doses a briefer negative phase and a lower and shorter positive phase or if no improvement takes place in the clinical symptoms, in spite of a very apparent positive phase, the indications are to increase the dose. And *vice versa* if an inoculation produces a prolonged negative phase with marked clinical symptoms, it is a safe conclusion that our dose has been altogether too large.

Our aim should be to regulate our doses so as to avoid the objective symptoms of the negative phase. It is now entirely possible to effect a cure by vaccine therapy without once inducing the toxic symptoms associated with the earlier attempts at immunization, and still frequently seen in the attempts of the ignorant and inexperienced. A toxic dose should never be given, and is always to be avoided if possible. The initial dose should, with rare exceptions, be small, and the increase gradual. This conservatism applies also to the frequency of the inoculations; because undue frequency may, like overdosage, do harm by inducing a severe or protracted negative phase. If at any time it is thought best to omit an inoculation, salt solution may be substituted for the vaccine, in order to hold the patient's attention.

Inoculation Therapy.—The principle involved in therapeutic inoculation is that a vaccine, consisting of killed bacteria of the same strain as that responsible for the patient's disease, be administered by subcutaneous injection in correct doses at appropriate intervals. We now recognize as a general law that such inoculations increase phagocytosis and thereby strengthen the body's principal organ of resistance to any specific microbe. By this means Wright has demonstrated that it is possible either to effect speedy and complete cures in many diseases of bacterial origin, or to ameliorate substantially the patient's condition.

The most brilliant results up to date have been obtained in localized infections. Microbes usually are found in more or less clearly defined foci of infection. This is so much more common than the diffuse distribution of the bacteria throughout the system which is found in generalized infections that it may be regarded as the normal type.

In infections where the invading bacteria have gained access to the general blood stream, such as septic endocarditis, vaccines if used at all should be administered early and in extremely small doses, though it might be permissible to repeat them with more than usual frequency. The opsonic index is an almost essential guide to dosage in such cases. Our vaccines should be autogenous ones, and the immunizator must very carefully feel his way both clinically and with the index, starting with a minimal dose. It is wiser to give repeated small inoculations with daily indices, rather than larger doses at longer intervals. A negative phase of any duration at all might be disastrous, because during such a phase of only a few hours' duration all the symptoms are apt to be profoundly aggravated, the toxemia is deepened, the temperature raised, and pain, if present, is increased. It is probable also that, owing to the low protective power on the part of the blood, the involvement of other tissues would be made possible and foci of suppuration might be initiated in many hitherto uninfected areas. We must bear in mind that our object in such cases in using a vaccine is to produce a rise in the protective substances of the blood, avoiding entirely any evidence of a negative phase, and our dose must be so small that there will be no delay in the elaboration of these substances.

Our only clinical guide in this type of pyrexial infections, when the osponic index cannot be estimated, beyond the conditions of any local lesion that might be present, would be the temperature. This has been used in some cases as a guide, a rise in temperature being taken as an indication of a lowering of the opsonic index. A marked fall in the temperature however after an inoculation in a general septic condition does not necessarily indicate that good has been done the patient; on the contrary it may designate, as already pointed out, a pronounced negative phase. I have read a report recently of a drop of six to eight degrees following maximal injections of streptococci in the treatment of septic endocarditis. This writer recorded such crises as favorable omens, whereas in reality they were the clinical evidence of a profound negative phase resulting from the depression of an overdose. The death of the patient followed as a matter of course.

The men who treat acute systemic infections of this type with the enormous doses we notice in

their published reports of cases, evidently do not understand the rudimentary limitations of vaccine therapy and it is not surprising that their mortality is very great. In this class of infections treatment with vaccines should be entrusted to inoculators who have had large experience and are accustomed to the determination of the opsonic index. The general practitioner should not attempt to treat such infections with vaccines because he will find the attempt fraught with no little risk to the patient.

In the localized infections on the other hand brilliant results may be almost uniformly expected. The most notable successes have been in the treatment of acne vulgaris, furunculosis, carbunculosis, subcutaneous abscesses, postoperative wound infections, postpartum infections caused by the *coli communis,* streptococcus, or staphylococcus, erysipelas, cystitis, gonorrheal joints, and tuberculous lesions outside of the lungs. But even in this class a profound or prolonged negative phase, resulting from an overdose of vaccine, may retard recovery, or do harm by making possible the involvement of new foci as a result of lowered resistance in the organism.

We must also bear in mind that good resistance in the circulating blood as evidenced by a high opsonic index may not necessarily react in the direction of a cure. Unless the protective substances in the blood have free access to the focus of infection they cannot prove effective. Such cases require measures to increase the local blood supply. Heat, Bier's suction apparatus, Bier's bandage to induce passive hyperemia are some of the means at our disposal to cause blood activity about such lesions. In the case of an old sinus, having a very poor blood supply because of imperfect drainage or coagulation of pent-up discharges, the indications are to flush it out, for which purpose nothing is better than a hypertonic salt and citrate solution consisting of 4 per cent. sodium chloride and 1 per cent. sodium citrate in sterilized water. The contents of such a cavity, whether it be the peritoneum, a pleuritic empyema, or an old abscess, may be low in protective substances while the by-circulating blood contains an excess. Drainage is followed by the introduction of fluids rich in protective substances derived from the blood, and recovery of the patient rapidly ensues.

Autogenous Versus Stock Vaccines.—While autogenous freshly prepared vaccines undoubtedly possess in many cases advantages over stock vaccines, nevertheless, owing to the difficulties and time necessary to secure pure cultures and for other reasons, stock vaccines are often advantageously employed. In the clinic and hospital work it is not always practical to secure autogenous vaccines and stock preparations seem to give fairly satisfactory results.

The stock staphylococcus vaccine prepared from recently isolated virulent cultures of *Staphylococcus aureus* and *citreus* is used at St. Mary's for practically all staphylococcal lesions, and only occasionally has it been found necessary to make a special autogenous vaccine. The stock streptococcus vaccine is used initially in acute cases; as soon however as the infecting streptococcus is isolated a special vaccine is almost invariably prepared, this being far more specific.

Most of the gonorrheal lesions we are called upon to treat are joint infections, where it is manifestly impossible to obtain a bacterial culture, so the stock vaccine has usually to be relied on. Stock tubercle vaccine is also most generally used, and in both these cases the results seem to indicate that they are as good as any.

Practically all other lesions, more especially those due to *Bacillus coli communis,* respond more promptly when treated with freshly prepared autogenous vaccines. It is possible for an experienced laboratory worker who understands Wright's technique to make autogenous bacterial vaccines at any time on short notice, particularly if the obtained specimen contains only a single organism. If more than one are present it may take several days to get pure cultures of the different ones. While we are waiting for the preparation of our autogenous vaccine, in order to save time it is always proper to resort to the temporary use of a stock vaccine.

If our patient is doing well on a stock vaccine it may be kept up; otherwise a special autogenous vaccine should be tried. If on the contrary the patient is not improving on a stock vaccine, and we are sure that the case is a suitable one for inoculation treatment, the logical thing to do is to prepare an autogenous vaccine and try that before abandoning the treatment.

Vaccines probably deteriorate by keeping and this is an objection to the stock ones. Furthermore the use of stock vaccines leads to the temptation of waiving bacteriological examinations, without which successful treatment cannot be expected.

Dosage.—In determining dosage only the reports of scientific men who have made an intelligent study of inoculation therapy are of value. The opinions of men whose experience has been limited to a few cases should not influence us, because they are of very little value. Clinical experience as a guide to dosage is not a safe teacher, because different strains of the same microorganism vary in virulence, and different patients show individual differences in their responses to vaccines. Of course careful study of the clinical symptoms should never be neglected in any case, but this should be corroborated in difficult cases by the opsonic index, our aim being to keep this high.

We must never forget that our vaccine is an opsonic stimulant only when used in proper dosage, and that an excessive dose depresses the immunizing mechanism of the body and retards the formation of the opsonin. It is always the part of wisdom to begin with a small dose and work up, remembering Ross's rule: "The more severe the case and the less satisfactory the clinical response the smaller should be the dose of vaccine employed."

The tendency of most beginners is to push the treatment as regards either the intervals or the size of the dose. This plan inevitably leads to disappointment, utter failure, or disaster. Do not look for an immediate cure; in tuberculosis cautious treatment of six to twelve months is often necessary before obtaining beneficial results. On the other hand if the patient's symptoms are aggravated, and it is evident that our inoculations are doing no good, particularly if no opsonic estimations are being made, it is wiser to discontinue treatment altogether after a few weeks. This applies particularly to general infections whether acute or chronic, particularly if the blood stream contains the microorganisms.

The negative phase is often our best guide to dosage; when it is absent altogether and the positive phase slight and of short duration the dose has

been too small; when it is prolonged, the dose has been excessive; and when it is moderate, and followed by a prolonged and distinct positive phase, the dose has been correct.

If the clinical symptoms of the negative phase are pronounced, *i.e.* excessive malaise, increase of pain, chills, or high temperature, the indications of course are to reduce the dose or to lengthen the intervals, or both. In phthisis, if the cough is aggravated and fever appears after our inoculations it is best to stop the vaccines altogether, otherwise the patient is made worse and may even be killed.

In all chronic conditions it is best to begin with minimal doses at 5 to 10 day intervals. Any hurry to increase the dosage is always to be deprecated, because minimal doses may do no harm, whereas an excessive dose may induce a severe or prolonged negative phase and undo whatever good may have accrued from previous doses.

In generalized infections small doses are to be insisted upon always. In all acute diseases with fever, such as pneumonia, and in all infections where the bacteria are found in the blood stream, such as infectious endocarditis, and in febrile pulmonary phthisis, the opsonic index is the only safe guide to the use of vaccines. If vaccines are to be used in these conditions, early administration and minimal doses at frequent intervals, with indices before each inoculation, are the essentials of safe, sane, and successful treatment. In only a few cases is it possible to lay down definite rules.

Summary.—An individual who has recovered from an infectious disease is ordinarily in no danger of taking it afresh, and this non-liability to take the disease a second time continues for a longer or shorter period. The investigations of Wright and others enable us by inoculating patients properly with bacterial vaccines not only to create in advance this state of resistance, but also to assist the individual after he has contracted an infectious disease to develop a resistance to the action of the invading pathogenic microbes, thus hastening recovery. This process is known as immunization.

By immunity we mean not only the non-susceptibility of a person to a given disease and the power to resist infection, but also the mechanism by which a cure is effected.

Opsonins are protective substances in the blood-serum, not yet isolated but proven to exist there, whose function it is to unite with bacteria and prepare them for the leucocytes to attack and destroy. Without such preparation Wright has demonstrated that the leucocytes are unable to ingest bacteria and this paramount defensive power of the organism is in abeyance.

The opsonic index of a patient's serum is the measure of his resisting power as comprised in phagocytosis against the microbe in question, and is expressed as a fraction of unity, above or below, according to the greater or less quantity of protective substances in the infected serum, as compared with the normal serum.

A vaccine is a standardized suspension of killed bacteria in physiological salt solution, preserved in lysol or carbolic acid.

Proper inoculations with appropriate bacterial vaccines have been proven by Wright to raise the opsonic index of the patient's blood, thus increasing phagocytosis and thereby strengthening the body's principal organ of resistance to any specific micro-organism. Vaccines accomplish results by producing active immunity.

In giving inoculations we aim ordinarily so to regulate the dose that a moderate "negative phase" lasting not over 24 hours is obtained. This is manifested by more or less malaise, slight rise of temperature, and some local reaction at the focus of infection. The positive phase should then ensue. The patient feels better and improvement is manifest. This should last from 3 to 10 days, when another inoculation is indicated.

If the negative phase is absent and there is a moderate but very short positive phase the dose has been too small. If the negative phase is severe or prolonged the dose has been too large. An excessive dose may produce a more or less permanent negative phase, rendering recovery very difficult and under certain conditions may cause the patient's death. Ross's rule, which he enunciated in connection with his treatment of erysipelas, is a good one to keep in mind: "The more severe the case and the less satisfactory the clinical response the smaller the dose." Or in other words, the more virulent the microorganism and the more generalized the disease process, the smaller should be the dose of vaccine employed.

Inoculations ordinarily are to be given twice a week, except in acne and tuberculous infections, when the intervals between doses may be a week or ten days, or even longer.

The whole study of biological therapeutics is in its infancy—in fact it has been only scratched upon the surface. The more experience we acquire, however, and the greater knowledge we have of the treatment of infectious disease processes by bacterial vaccines, the more convinced de we become of the importance and value of this method.

Inoculation therapy applies particularly to the treatment of diseases of bacterial origin which have failed to respond to the usual methods of treatment, and to stubborn chronic cases. The best results have been obtained in strictly localized processes, both chronic and acute. In certain infections vaccines, properly applied, have been proven to be an absolute specific. In this class we include erysipelas, acne, the furunculosis group, carbuncles, gonorrheal arthritis, and cellulitis. Brilliant results may be almost uniformly predicted from vaccines in most septic localized processes of staphylococcal and streptococcal origin. Osteomyelitis seems to be particularly amenable to proper and appropriate vaccine inoculation, especially in its chronic form. Certain severe forms of chronic eczema, sycosis barbæ, ciliary blepharitis, pyorrhea alveolaris, infections of the accessory nasal sinuses, otitis media, cystitis, ureteritis, pyelitis, chronic sinuses, whitlow, styes, subacute puerperal infections, postoperative infections, and septic wounds have all been cured by inoculations, when administered by expert hands.

Chronic infections characterized by a continually low opsonic index due to the absence of autoinoculation from the escape of bacteria or their products from the disease focus into the adjacent lymph or blood stream are types of cases in which vaccines are clearly indicated. In such conditions it may be necessary to use measures to increase the local blood supply, such as heat, Bier's suction apparatus, etc., in addition to the bacterial inoculations.

Tuberculin vaccine, properly administered, is of the utmost value in the treatment of localized tuberculosis of the glandular and genitourinary system, tuberculous sinuses, bones, and joints, tuberculous peritonitis, and tuberculous skin ulcerations. Before beginning treatment in this class of infections it is

most important to examine the lungs carefully, because, if phthisis is found to coexist, our inoculations must be administered with the greatest caution and in minute doses, otherwise the lung involvement may be seriously aggravated. In pulmonary tuberculosis immunizators agree that treatment must be begun early in the disease if it is to be of much service. In certain selected cases, more particularly if nonfebrile, vaccine treatment in expert hands is of undoubted value. Improper treatment by amateur inoculators may aggravate the symptoms and hasten the patient's death. In most disease processes where vaccines are indicated beneficial results are apparent almost at once, if they are to be obtained at all. In tuberculous affections, however, treatment must be kept up for a long period before there is any improvement, and the patient should be told at the outset not to look for noticeable benefit short of six months or a year.

The infections in which bacterial inoculations are contraindicated are the acute and diffuse generalized disease processes, characterized by fever and other evidences of systemic infection, where the index may be continually low because of a permanent negative phase caused by excessive dosage from autoinoculations. Types of these infections are ulcerative infectious endocarditis and puerperal septicemia where the infectious microbes are present in the blood stream. Our only hope from vaccines in such cases would be to raise the resisting power of the blood, as shown by the opsonic index, by very cautious minute doses, administered *early* in the disease before the patient's immunizing mechanism is permanently disarranged.

We also include in the class of contraindicated cases acute febrile infections like pneumonia and typhoid fever, and infections in which autoinoculation is the characteristic feature, where the opsonic index fluctuates at frequent intervals from high to low and *vice versa*, because autoinoculations of varying amounts are continually taking place. In such cases a dose which might be appropriate one day would be entirely improper the next, and any attempt to administer a vaccine without an opsonic estimation before each inoculation would be a manifestly foolhardy expedient. Acute phthisis pulmonalis with fever is a type of this latter condition. In all such conditions vaccines, if used at all, should be administered only by expert immunizators and in conjunction with the opsonic index. The inoculations may be more frequently repeated perhaps, taking great care to avoid any evidence of a negative phase, because even a very brief negative phase would make possible the involvement of other tissues, and foci of suppuration might be initiated in many hitherto uninfected areas.

Inoculations with vaccines during convalescence may hasten recovery.

Prophylactic inoculations have been proven to afford absolute immunity against typhoid fever and several other infectious diseases.

Inoculations may be safely given without the aid of opsonic estimations in many staphylococcal, streptococcal, gonococcal, localized tuberculous infections, and in acne. Immunizators agree however that in certain difficult cases and in all serious active acute infectious diseases, with fever or complications, vaccines cannot be used either safely or intelligently without opsonic determinations, except by expert and experienced inoculators. In such cases the direct observation of the state of the patient by the opsonic index is most important and oftentimes absolutely necessary. It indicates exactly how far the resisting forces of the body have been affected and gives valuable and reliable guidance as to dosage, intervals between inoculations, and the details of further treatment.

The opsonic index may not be mathematically exact; but it is sufficiently accurate to prove a valuable guide to the expert immunizator in the practical application of bacterin therapy to the treatment of infectious diseases. While the patient is under continuous observation with the opsonic index the inoculations may be safely increased if the indications are to do so, whereas, without the index to guide us, conservative therapeutics might suggest such small doses that the progress of the disease would not be arrested, and the cure of the patient needlessly delayed.

High opsonic power usually means amelioration of local and general symptoms. In a patient recovering from an infectious disease there is an elevated index. Whereas with a low index we have chronicity and local and general clinical symptoms which indicate correspondingly low resistance to the infecting bacteria. It is our aim therefore in administering vaccines to maintain an average high level of resistance.

In many cases of obscure origin as an aid to diagnosis the opsonic index is a valuable guide.

Few laboratory workers in this country fully understand Wright's technique for estimating the opsonic index. Most of the criticism we hear and the reports of contradictory findings are due to imperfect technique, lack of experience, and inability on the part of amateur opsonists to interpret their own work correctly. The technique must be painstaking, conscientious, and absolutely faultless if reliable results are to be obtained; in other words the index is valueless unless it is estimated by an experienced and expert opsonist who uses the correct technique. Bad and unsatisfactory results with vaccines and the opsonic index are almost invariably the result of ignorance, inability to understand the limitations of the science, and misapplication of it in contraindicated cases.

Autogenous freshly prepared vaccines are to be preferred to stock vaccines when it is practical to obtain them without too great delay. In staphylococcus infections, in erysipelas, in tuberculous lesions, in gonorrheal bone and joint involvement, in acne, and for prophylactic immunization the stock vaccines are regularly used at St. Mary's with almost uniformly good results. Rarely has it been found necessary in any of this class of cases to prepare a special autogenous vaccine.

The investigations of Wright and others demonstrate that natural recovery from infectious disease is due to the development of a condition of immunity in the body and that this is accomplishel largely through autoinoculation. This may be either spontaneous or artificially induced, by exercise, massage, poultices, or Bier's apparatus. Experienced immunizators have made use of artificially induced autoinoculations as a therapeutic measure where bacterial inoculations have been refused or for any reason have been found impractical, and the results obtained compare very favorably with those following the use of vaccines.

In many acute febrile infections autoinoculation may be excessive, and a consequent heavy negative phase retard recovery; hence the necessity in such cases of absolute physical quiet and rest in bed. On the other hand, the nonfebrile subacute, chronic,

and convalescent cases may be benefited by judicious autoinoculations induced by graded periodic exercises or in some other way.

Localized infections may be cured by measures to increase the blood supply to the focus of infection, such as poultices and Bier's apparatus, in two ways; first the increased blood supply brings to the infected tissues a greater amount of the blood's protective and immunizing substances; and, second, bacilli or their products are carried from the infected focus into the general circulation, thus inducing a beneficial autoinoculation.

The best place to learn opsonotherapy and the science of bacterial immunization is in London under Wright himself, because his presence in the laboratories and clinics, surrounded by a coterie of well trained assistants, makes the student feel that at St. Mary's, Paddington, he is indeed at the very fountain head of knowledge. If a trip to London is not practical the next best course is that given by Dr. G. W. Ross at the Toronto General Hospital. The facilities in Toronto in the way of laboratories and clinics cannot, of course, be compared with those offered in London, but, nevertheless, it is possible to acquire the opsonic technique and to learn the practical application of vaccines there successfully, and this a score or more of men have done.

The domain of inoculation as a curative agent is a wide one and offers an almost boundless field for study. To make the list of successes, already a long one, more complete needs only more scientific workers in the field. Although vaccines have been shown to have a wide field of usefulness in practical medicine, considerable study is required to understand the *modus operandi* of their intelligent use, and because of the special knowledge and skill necessary to employ them safely and the danger to the patient from their improper application they will probably never be in general use. Nor as a matter of fact should they be used by any but the duly and properly qualified. Under no circumstances should they be regarded as a panacea or "cure all."

AN EASY AND CERTAIN METHOD OF DIAGNOSING AND FOLLOWING A FISTULOUS TRACT.

By JEROME M. LYNCH, M.D.,

NEW YORK,

SURGEON NEW YORK POLYCLINIC, ST. BARTHOLOMEW'S, AND ST. MARY'S HOSPITALS.

From time immemorial numerous and divers methods have been devised for following the ramifications of a fistulous tract; but, so far as I know, none of the methods yet suggested are absolutely reliable. In the simple fistula the flexible probe will meet all the requirements, but even in these cases those who are inexperienced have difficulty in guiding a probe from one opening to the other and if the probe is not of the required flexibility it is

Fig. 1.—From a photograph of a "watering-pot" fistula. Note the brawny swelling above, just where the probe is inserted into the distal opening.

apt to go astray or form a false passage; and I might say in passing that the probes most frequently used (that is judging by those offered for sale in the houses of the different instrument makers) are far from meeting the requirements that we have mentioned.

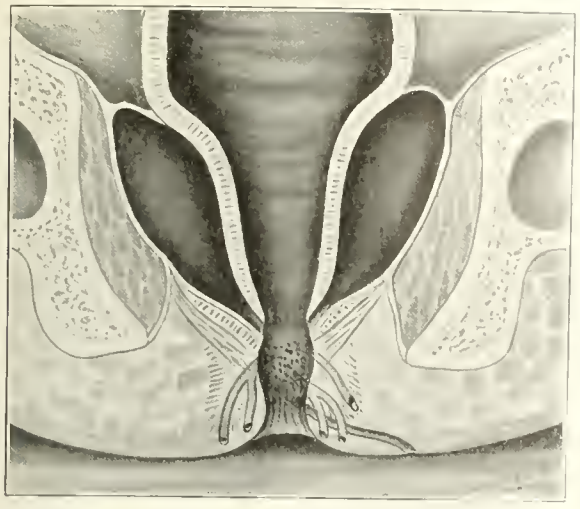

Fig. 2.—Diagram illustrating the condition in Case 1 after operation, showing where the tracts seen in Fig. 1 opened into the rectum.

There is no condition in the whole range of surgery apparently so simple, and yet, judging by results, none where the percentage of failures (in the hands of the average surgeon or general practitioner) is so great. Even the most skillful meet accidents from time to time, resulting in failure to cure, because they fail to discover the internal opening of the fistulous tract, overlook it, or pass by some one of the numerous ramifications at the time of the operation. Is it to be wondered at then that the general public hold the opinion that this condition is incurable? No doubt this impression is, to a certain extent, due to the fact that fistulæ in the tuberculous are difficult to cure. Another reason is probably due to the fact that tuberculous fistulæ are opened by the knife instead of the cautery, resulting in the opening up of the lymphatics and blood-vessels and allowing the tubercle bacilli to find their way into the general circulation, resulting in general disseminated tuberculosis.

It is a good many years since Prof. Hartman of Paris brought this subject before the medical profession yet, judging by the papers one reads and the failures we have seen resulting from the use of the knife in these cases, we must conclude that the teachings of Prof. Hartman have not yet permeated the medical profession to any great extent.

If a tuberculous fistulous tract is examined under the microscope it will be found to consist on the inside of granulation tissue filled with tubercle bacilli and giant cells, and on the outside of this a strong, thick wall of connective tissue. The innermost portion of this wall may be found to have some tubercle bacilli, but the tubercle bacilli have never been known entirely to permeate this safeguard provided by nature for the protection of the body against them. Now if this provision of nature is broken down and cut through by the knife the tubercle bacilli will immediately find their way into the general circulation, and all the conditions being favorable on account of the lowered vitality of the individual the chances are ten to one that a general tuberculosis will result.

Take a case where an individual has a suppurative process but yet is protected by a wall of connective tissue. He goes to a surgeon and the surgeon breaks down this wall. The impression then goes abroad that such cases are incurable. On the contrary when opened by the cautery all the lymphatics and blood-vessels are sealed, and if afterward the proper treatment is instituted these cases almost invariably get well so far as this local condition is concerned.

A fistulous tract is seldom straight and as the caliber varies at different places along its course this is one of the reasons why great difficulty is experienced in following the tract with a probe as illustrated by Figs. 1, 2, and 3. All of these cases were injected with methylene blue and peroxide of hydrogen before operation and the writer is sure that if this method had not been adopted we would not have discovered some of the ramifications of these complex tracts. Fig. 1 was photographed by the writer at St. Bartholomew's clinic and subsequently the case was operated upon by one of my colleagues, Dr. Humphreys. I am indebted to him for the drawing from which Fig. 2 was made. The patient made an uneventful recovery. To relate all the suggestions that have been made for marking out and following this tract would be to relate the literature of fistula for the past thousand years. A few that have been suggested and have some merit but have not come up to the requirements are methylene blue, permanganate of potassium, bismuth paste, numerous other coloring fluids, and so on.

The tracer I have used for the past eight years (but have not before published) is a mixture of peroxide of hydrogen and a saturated solution of methylene blue. We have demonstrated time and time again the value of this method as a means of diagnosis, and of its almost unvarying reliability in those very complicated fistulous tracts where the communication between two fistulæ was so narrow as to make it impossible for any probe to pass no matter how fine, especially when the angle between the transverse and longitudinal fistulous tracts was very acute. This, to my mind, is the simplest and the most reliable method of following the ramifications of the tract so far devised. The peroxide of

Fig. 3.—Drawing from an *x*-ray picture taken by Dr. MacKee before the operation.

hydrogen will carry the methylene blue into the finest ramifications of the tract, the methylene blue stains the tract, and when the surgeon comes to operate it is a very simple thing to follow it. This method given a trial will be found especially invaluable to the man who operates in such a case only

occasionally and would obviate many failures that undoubtedly result from overlooking some ramification of the fistulous tract or neglecting to find the internal opening.

Before closing I must say a few words about the after-treatment of these cases and, as we know, the after-treatment is fully as important as the operation. There are any number of men who can perform a perfect operation in a difficult case, but I have seen bad results after the very best work of the best surgeons, men of unquestionable surgical skill, who stand at the head of the profession to-day. I want to suggest why these cases result in failure. A perfect operation is performed and the busy surgeon not having time (or perhaps the inclination) to do the after-treatment turns the case over to his assistant. He, in all probability, is a young man with a laudable desire to do great things but with his limited experience only able as yet to do small things. The result is that the patient is frequently dressed in a haphazard manner, the fistula granulates and in the course of time has apparently healed, but soon afterwards there occurs an acute exacerbation, possibly an abscess, but, at any rate, the patient still has his fistulous tract. What has happened? Some bridging very possibly occurred during the healing process, leaving a little opening, or else the fistulous tract healed overhead, or the outer portion of the tract healed up, and the imperfect healing of the inner portion resulted in this delayed healing or apparent cure, the fistula to recur at some future time. The reason that a specialist gets better results in such cases is because he exercises a watchful supervision until the patient is thoroughly healed. If at any time during the course of healing he finds, owing to pain or some other indication, that there is a collateral tract that has been overlooked he immediately opens up that tract before the mischief goes any further. He puts his finger in the rectum once or twice a week, noting any irregularity there; if there is any bridging that bridge is broken down; he does not pack the fistulous tract; he does not necessarily apply any medication; but he keeps his eye on that fistula until the patient is absolutely well. And that is the reason why the specialist gets results which the general practitioner is very apt to miss.

58 West Fifty-eighth Street.

ARE PNEUMONIA AND RHEUMATISM SPECIFIC INFECTIONS?

By THOMAS G. McCONKEY, M.D.,

SAN FRANCISCO, CAL.

In the list of diseases in Osler's "Practice of Medicine" classified as "Specific Infectious Diseases" we find pneumonia and rheumatism. The list is as follows: typhoid, typhus, relapsing fever, smallpox, cowpox, chicken-pox, scarlet fever, measles, rubella, mumps, whooping cough, influenza, dengue, cerebrospinal fever, pneumonia, diphtheria, erysipelas, septicemia and pyemia, rheumatic fever, cholera asiatica, yellow fever, and several others, ending with leprosy. If this list is studied it will be found that most of the diseases mentioned are due to a specific agent and one attack usually protects from a subsequent attack. In strong contrast with the true acute specific infections, one attack in pneumonia and rheumatism not only fails to furnish immunity but seems actually to predispose to subsequent attacks. This important clinical fact should arouse the suspicion that they are not real specific diseases. Again, the bacteriologists are not agreed in respect to the specific organism and the controversy has run in almost parallel lines in respect to the etiological agent in both. The penumococcus it is agreed is the usual cause of pneumonia. It is variously called the *Diplococcus pneumoniæ, Micrococcus pneumoniæ cruposæ,* and Chester in his recent classification calls it the *Streptococcus pneumoniæ*. But the *Diplococcus pneumoniæ* may be found in many other conditions besides pneumonia. Osler says of it: "It has been found also in pleurisy, *pericarditis,* meningitis, peritonitis, *acute synovitis,* otitis, *endocarditis,* etc." I have italicized certain of these to call attention to the fact that the pneumococcus is perfectly able to cause the symptom-complex we call "rheumatism." Poynton, who contributes the article "Acute Rheumatism" in Osler's "Modern Medicine," feels sure that he and Paine have proved that the specific cause of rheumatism is a streptococcus which they named the *Diplococcus rheumaticus* in 1901. But he admits that there are several views still prevalent and enumerates them thus: "(1) That there is no specific microorganism, but the disease is a form of septicemia which owes its origin to staphylococcal or streptococcal infections; (2) that the disease is due to a specific bacillus; (3) that the microorganism is a diplococcus; (4) that the exciting cause is as yet unknown." Poynton says that the exciting cause of rheumatism is "variously called a diplococcus, streptococcus, or micrococcus." As may be seen, this terminology is identical to that applied to the pneumococcus. Even did the *Diplococcus rheumaticus* show cultural differences from the *Diplococcus pneumoniæ* it would not negative the essential identity of the two, for the streptococcus may show cultural differences when obtained from different sources. If Poynton noted the essential identity of his *Diplococcus rheumaticus* with the *Diplococcus pneumoniæ* he does not mention it. Indeed he would find it difficult to reconcile the fact with his conception of rheumatism as a specific disease. Now if it can be proved that there are no such specific diseases as "rheumatism" and "pneumonia," as typhoid fever and smallpox are specific diseases but that each is a mere symptom-complex caused usually by the streptococcus as a secondary invader, though other secondary invaders, as staphylococci, can cause the same symptom-complex, we would be able to understand and reconcile the bacterial findings in these two diseases. And more important than this we would have the proper conception of the diseases themselves. Let a miscellaneous group of persons get wet from an unexpected rain, with the necessity of remaining in their soaked garments for some hours. Many of them will "catch cold" which eventuates in pneumonia in some and in rheumatism in others. Does a mere wetting cause a specific infection like smallpox or measles? To ask the question is to answer it. Now why does the same exposure cause in one a pain in the side and later consolidation of a lobe or lobes of the lung while in another it causes an acute synovitis or endocarditis? It is not an adequate answer to shrug the shoulders and oracularly say that is because the lungs or joints, as the case may be, are the weak spot in these persons. Is it not possible to explain why the pleura or joints are so susceptible in certain persons to this acute inflammation? Yes, and the answer gives one the key to the fundamental cause of both penumonia and rheumatism. The tubercle bacillus was the primary fac-

tor and prepared a congenial nidus for the lodgment and growth of the streptococcus or other organism which is responsible for the acute condition. The streptococcus is a normal inhabitant of the mouth and nasal cavities, but is prevented from gaining access to the circulation by the watchful activity of the phagocytes of the tonsils and ring of lymphoid tissue of the pharynx. The lowered temperature following the exposure so lessened the usual efficiency of the protective mechanism, in certain individuals of the crowd, that the streptococci were enabled to pass this first line of defense and get into the blood and finally get a lodgment on the pleural surface where they multiply in great numbers and are absorbed with the pleural transudate, thus causing a pneumococcemia or staphylococcemia if the organism happens to be the staphylococcus instead of the streptococcus. I have shown in a previous paper that the consolidation of the lung, the cardinal symptom of pneumonia, is a sequence of the leucocytosis evoked by the bacteriemia (Medical Record, October 30, 1909). I refer those interested to this paper for my conception of pneumonia. A summary of this paper was printed in the year-book on "General Medicine," edited by Dr. Billings and Dr. Salisbury of Chicago. This would imply that the editors considered it one of the valuable contributions to medicine of the year.

In articular rheumatism the diplococci are localized in the periarticular tissues and a few may be found in the synovial fluid, but there is not the same opportunity for absorption and for thus reaching the general circulation that there is from the pleural cavity. This is known to be simply an expanded lymph space as are all the serous cavities when studied in connection with the lymphatic system. Hence the temperature in articular rheumatism is caused by the local inflammation and is commensurate with it. Poynton says: "It is difficult and exceptional to succeed in demonstrating the diplococci in the blood, for they are localized in the various lesions. This can be done, however, when the disease is very severe and *generalized*." (Italics mine.) In explanation of this generalized form he says: "The malignant type is best exemplified by certain cases of rheumatic endocarditis in which the microorganisms are not destroyed in the tissues but multiply in the *damaged valve* and are then disseminated by the blood stream throughout the system. In the most severe form *the vegetations on the valves* are minute and yet there are immense numbers of bacteria in them; in those of less severity there are large *fungating vegetations* in which many bacteria may be present but in which many may be destroyed." I italicize certain words of this quotation from "Modern Medicine" to emphasize the fact of previous damage to the valves and the nature of that damage. Now vegetations, whether minute or large fungating growths, are essentially chronic processes and it has been proved that the tubercle bacillus can cause them. Schueller, in support of the tuberculous theory of joint inflammations, rendered guinea pigs and dogs tuberculous by the injection into the lungs of tuberculous sputum and by causing others to inhale the same material. He then wrenched and strained the knee joint, and in the greater proportion of cases a fungous synovitis followed, but not so in healthy animals. Hueter demonstrated that tuberculous matter injected into the joint will cause a fungous hyperplastic synovitis, and Koenig by introducing the fungous proliferations of synovitis into the general circulation of animals caused general tuberculosis. We have known for some time that in childhood the bones and joints in showing tuberculous conditions are exceeded only by the lymph-nodes. On account of the tendency to recur and especially to become chronic rheumatism was called an "acute-chronic" disease. Contradictory as this appelation appears, clinically, as a descriptive term it is quite appropriate. This was during the first half of the nineteenth century before there was such a science as cellular pathology or bacteriology, and when they had fewer facts than we and were compelled to draw their conclusions from clinical study. In our pursuit of laboratory facts we have neglected the art of deducing generalizations from the facts—especially clinical facts. The result is there is a mass of unclassified facts which remain almost useless and unapplied in the practical art of medicine. We can now see why the term acute-chronic is singularly appropriate when applied to rheumatism, because the acute symptoms are due to a secondary invader and the chronic features to the tubercle bacillus. Poynton incidentally remarks that "in man early endocarditis, whether pneumococcal, rheumatic, or staphylococcal or tuberculous in causation, has much the same superficial appearance," but has no explanation to suggest. Any reader who has followed my argument thus far will at once see that they have the same superficial appearance because the tuberculous causation is common to all of them, and further that the pneumococcal and rheumatic causations are really of one kind instead of two. While rheumatism is more frequently associated with endocarditis than any other diseased condition, pneumonia is next in frequency and is said to be the cause of 20 to 25 per cent. of all cases of endocarditis. But instead of the pneumonia being the cause of the endocarditis the consolidation of the lung is the result of the endocarditis. We saw that in the severe or generalized type of rheumatism the diplococci are actually found in the blood and that even though the vegetations on the valve are minute "yet there are immense numbers of bacteria in them" and that they "are then disseminated throughout the system." If my conception of the pathology of pneumonia as detailed in the paper, "Is Lobar Pneumonia Inflammation of the Lungs?" be correct, we should anticipate a consolidation of the lungs also in this severe type of rheumatism. "Pneumonia," says Poynton, "occurs in the severe type of acute rheumatism." Musser says: "Acute arthritis as a complication in pneumonia has long been recognized, but was classed by the older writers as rheumatism." Musser also calls attention to the frequency with which endocarditis is overlooked in pneumonia and quotes the findings of twelve clinicians, including Osler, which aggregate 504 cases of pneumonia, 114 of which had endocarditis, or 22.6 per cent. From my point of view these are to be interpreted not as complications of pneumonia but as cases of endocarditis followed by pneumonia incidental to the bacteremia. Musser states that "acute endocarditis may occur in animals experimentally inoculated with the pneumococcus, but generally only if the valves have been previously injured." The view that acute endocarditis in man is secondary to previous injury of tuberculous causation is thus corroborated experimentally.

The question naturally arises: Have we any actual evidence of these minute vegetations in the absence of rheumatism, pneumonia, or acute endocarditis? I will answer by quoting from Osler:

"Simple endocarditis is characterized by the presence on the valves or lining membrane of the chambers of minute vegetations, ranging from one to four mm. in diameter, with an irregular and fissured surface, giving to them a warty or verrucose appearance. The vegetations are on the line of closure of the valves. . . . As a rule no microorganisms are found in the simple endocarditis in many chronic diseases, as carcinoma, tuberculosis, nephritis, etc. . . . The great majority of the cases are latent and there is no indication whatever of cardiac mischief." We saw that Schueller produced tuberculosis synovitis in infected animals by severe twisting and wrenching of the joints. This is duplicated in children by accidents and strenuous games. The jumping from considerable heights on hard pavements might easily cause contusions in the joints that would lead to the lodgment of tubercle bacilli. To account for the vegetations on the valves of the heart it is sufficient to recall the fact that they "are on the line of closure of the valves," and that in rheumatism there is usually a high blood-pressure in strong contrast with the low tension in pneumonia. High tension implies a strong heart and accentuated second sound. The abnormal violence of this closure of the valves could easily have the effect of a contusion and thus favor the lodgment of the bacilli. This contrast in respect to blood-pressure in pneumonia and rheumatism is really more significant than the numerous other analogies; for this fact of high or low blood-pressure is the determining factor in the accident of the location of the tuberculous lesion, excepting in the case of the joints, in which, as we have seen, the lesion is probably of traumatic origin. We have already seen that high tension causes such increased violence of the closure of the valve that it is even perceptible as an accented sound to the ear. Is it any surprise that this violent impact kept up constantly at the rate of once or more every second should determine the lodgment of bacilli and the production of lesions along the line of closure? Now on the contrary in pneumonia, which is usually sequent to pleurisy rather than to endocarditis, a low blood pressure is found. The pleural cavity is a lymph-space and its contained serum and that bathing its surfaces is properly designated lymph. An increase in blood-pressure causes an increase in the amount of lymph and conversely. Therefore in persons of low blood-pressure the pleural surfaces are less well "lubricated" with lymph and the bacilli carried by the lymph stream from some scrofulous lymph-node becomes stranded as it were on the pleura and generally at the apex; for obviously this would be the shallowest spot, as the rest of the surface has not only its own transudation of lymph but that brought down by gravity from above as well. (This is the real explanation of tuberculosis of the apices.) As is well-known, the pneumonia or pleurisy victim is very prone to tuberculosis of the lungs, while the rheumatic subject is likely to go with chronic heart disease.

Poynton is evidently not satisfied with his own view of rheumatism for he says that neither the term acute rheumatism or rheumatic fever is satisfactory, and we clearly need a term corresponding to tuberculosis. This shows how near he was to solving the problem of the nature of rheumatism and yet just missed it. "The onset of rheumatism," he says, "especially in childhood, differs widely in its characters. Thus it may be insidious and preceded by a period of indefinite illness, which can be but compared to the gradual failure of health that *so frequently precedes tuberculosis* (italics mine). The following symptoms, among others, are met with in this prodromal stage: anemia, nervousness, irritability, epistaxis, loss of energy, wasting, headache, sore throat, epigastric pain, and fleeting pains in the joints. The temperature is usually above the normal, *e.g.* 99.5° F." Why Poynton failed to see that these symptoms, which "can only be compared" to incipient tuberculosis symptoms, are actually due to the tubercle bacillus would pass understanding if we did not know how blinded we all may be to the most obvious truth by false preconceptions.

To recapitulate: (1) Pneumonia and rheumatism are not specific infectious diseases, like typhoid or smallpox, but each is a mere symptom-complex dependent upon and secondary to tuberculous vegetations or lesions on the pleura, pericardium, endocardium, or periarticular tissues. (2) The streptococcus normally present in the mouth and nasal cavities is the most frequent secondary invader of this abnormal tissue; but staphylococci, Friedländer's bacillus and the specific microorganisms of typhoid, diphtheria, gonorrhea, etc., may also be secondary invaders as well. (3) Whether the symptom-complex called pneumonia or the one called rheumatism occurs depends upon the accident of the location of this damage of tuberculous causation. (4) If situated on the pleura, pneumonia is the diagnosis provided consolidation occurs, otherwise it is called pleurisy. If situated in the joints alone or in connection with the endo- or pericardium, it is diagnosed rheumatism. If situated on the endocardium alone and not followed by consolidation of the lung, as it frequently is, it is called endocarditis; but if consolidation occurs it is erroneously called pneumonia complicated with endocarditis.

1156 Sutter Street.

THE CAUSATION OF BELCHING.

By DUDLEY ROBERTS, M.D.,

BROOKLYN, N. Y.

Belching, according to popular conception, indicates an excess of gas in the stomach. Fermentation is thought to be the explanation of this gas. Certain foods we constantly hear spoken of as "gassy" and the large majority of all abdominal discomforts are thought, in some way, to be connected with the abnormal presence of gas. Judging from the frequency with which gas-absorbing and combating drugs are given, it would seem that many clinicians still hold to this idea, which has so little basis in fact. The meaning of the phenomenon to those who have given it any critical study is entirely different from this one, which, superficially considered, seems so simple and satisfactory.

In the first place, it may be stated that there is no necessary relation between the amount of gas in the stomach and the complaint of gas or belching. Dilatation of the stomach by gas is unusual in the extreme and, on examination, those who talk most of gas give no evidence of its presence in abnormal quantities. It is an interesting fact that a rush of air through the stomach tube is rarely heard until air has been pumped into the stomach for diagnostic purposes.

In the second place, we may say that gas generation rarely takes place in the stomach. Theoretically it is easy to see how unlikely is such generation under ordinary conditions. Complete emptying of the stomach takes place during the night if not be-

tween meals. The acidity at the end of each meal is destructive of bacteria. While the food is digesting the constantly increasing increasing acidity is inimical to the growth of microorganisms. Bacteria sufficent in numbers to raise more than a negligible amount of gas cannot well grow in the short time previous to the appearance of a more or less pronounced acid reaction.

Experiments carried on with extracted test meals rarely show, even after days, that gas can be developed in chyme. Even if inoculated wih gas-producing organsims there is rarely a growth. If there is stasis, however, and the stomach is not entirely cleaned each night there may be a growth of gas-producing organisms. This is not the case where there is merely atony and slow emptying or partial pyloric obstruction with delayed emptying. Anacidity combined with stasis is the one condition which is ideal for the generation of gas and this rarely occurs except as a result of gastric carcinoma. Occasionally one finds some gas generation possible in the chyme from cases of stenosis and ulcer with normal or supernormal acidity. This is due to growth of yeast. The actual generation of gas in these cases seldom amounts to more than a trifle. Days not hours may be required to show any development whatever.

With the exceptions mentioned the so-called gas in the stomach is swallowed air, introduced with the food and in the act of swallowing. When one is in the erect posture this air is carried in the fundus of the stomach above any fluids and solids that may be present. The air-filled fundus is in important relation to the diaphragm and heart. The escape of air after anything is taken into the stomach may take place unobtrusively and is not necessarily a morbid phenomenon. Some air is also very probably absorbed in the blood.

The tendency to air expulsion is determined in large part by the following factors:

1. Any increase in the volume of solids, liquids, or gases in the stomach tends to distend the fundus with air and press on the cardiac sphincter.

2. Limitation or diminution of the size of the stomach by pressure from without or by its own musculature tends to distend the air-filled fundus and increase the pressure of air upon the cardia.

3. The state of contractility of the cardiac sphincter determines the ease with which air is forced from the stomach.

Clinically there is one fact of considerable importance in the study of belching whether of a normal or abnormal degree. Eructation of gas *may* be entirely involuntary but belching is usually a voluntary act. Some sensation referred to the stomach gives rise to the idea and the individual in some way assists in the expulsion of air. This is entirely comparable to the passage of flatus from the bowel; either act may take place during unconsciousness but is usually conscious and voluntary.

This expulsion of air seems to be brought about in different ways. At times it is merely by the setting of the diaphragm and abdominal muscles, the degree of effort depending upon the amount of stomach content and the tone of the cardia. Again air is aspirated into the stomach and brought up by muscular effort. Some become very proficient in the act of distending the stomach with swallowed air, but it is an accomplishment seen rather infrequently. Air swallowing ordinarily consists in the gulping of air into the esophagus and the consequent gulping up again.

It is obvious that if belching is a voluntary act it may be carried to extremes for one reason or another. Such exaggerated belching is commonly met with in practice and it is easy to assume that the exaggeration indicates a neurotic tendency. There is in such an assumption considerable danger of attributing too much to the mental state. It belching gives relief from real or fancied distress in the stomach or, more properly speaking, upper abdomen, its practice is apt to become habitual either for the immediate relief of discomfort or through fear of the possible occurence of discomfort. I am of the opinion that too much stress has been laid by certain clinicians on the neurotic character of belching. Many cases have come under my observation with a diagnosis of nervous dyspepsia because of the seeming neurotic character of the habit of raising gas. Back of the habit has been the desire for relief from gastric distress. Such distress may arise from a great variety of conditions, gastric or otherwise.

In studying the phenomenon clinically I have been impressed with the fact that there is considerable diagnostic value in the character of the attack, the time of its appearance, and its relation to other facts and phenomena. It is met with as a result of certain fairly well-defined abnormalities some of which are of such like character that an arbitrary grouping upon an etiological basis is possible.

Aerophagic Types.—Habitual belching, or attacks of more or less severity, is frequently met with in the hysterical, hypochondriacal, and emotionally excitable. The belching is usually noisy and designed to attract sympathy and attention. The patient complains of the belching and not of any sensation which he is trying to relieve. No relief is felt. It is an evident nervous exaggeration. Some aspirate air and balloon the stomach, others gulp air and can do it on request. These attacks bear no relation to the ingestion of food or any other event except some obvious or obscure psychic disturbance.

A mild form of aerophagia is sometimes seen in very nervous individuals immediately after partaking of even the smallest and blandest meal. There is a slight feeling of discomfort and efforts are made to raise imagined gas.

Dietetic Types.—Very fast eaters, large eaters, and those who drink too much with their meals have a mild form of belching directly after eating. There may be too much air ingested or too little space left for a small amount. Relief is felt after a little involuntary eructation or voluntary belching.

Pressure Types.—As a result of tight clothing, distention of the abdomen with fat, fluid, tumors, or the pregnant uterus the capacity of the stomach may be limited. The discomfort is most pronounced immediately after eating. Heartburn, not necessarily from a real hyperacidity but from the constant lifting of the acid chyme up into contact with the cardia, is often complained of in this class of cases.

Cardiovascular Types.—In disease of the kidneys, heart, and blood-vessels resulting in constant or occasional embarrassment of the heart action belching is often one of the most troublesome complaints. Relief is felt when the gas is brought up and the trouble is attributed to the gas in the stomach. These patients frequently consult the clinician first for supposed digestive disturbance. Dyspnea is an important part of the history but not

always elicited without careful cross-questioning. In arterial hypertension and angina these gas attacks come without warning, particularly on exertion. The excited and exaggerated efforts to raise the gas often lead to mistaken diagnoses. The patient alarmed by his disease is thought to be essentially neurotic. Aerophagia develops in those of a nervous disposition.

Peptic Ulcer Types.—In gastric or duodenal ulceration or carcinoma in its early stages, if developed on an ulcerative base, there is usually a complaint of gas at the time of the period of pain, one to four hours after the ingestion of food. Like the pain, the belching is relieved by eating and drinking and by alkalies. I have met with a number of instances in which belching in each or some attacks was the chief or only complaint. Like the characteristic pain, it comes when the stomach is empty and is stopped by food ingestion. *I have come to regard "hunger belching" as a complaint of great significance.* These patients usually complain of the sour, bitter fluid coming up into the mouth with the gas or alone. The belching of itself gives some relief from the epigastric discomfort and these patients develop the habit of belching in an aggravated degree.

Gall-Bladder Types.—In disease of the biliary tracts, at the time of severe attacks, efforts to raise gas are sometimes pronounced, although no particular relief is felt. The agonizing pain drives the patient into exaggerated attitudes and efforts to gain relief. Many so-called gastric disturbances characterized by bloating, belching, feeling of epigastric distress, and the like are due to chronic disease of the biliary passages. These patients complain that gas lodges in the stomach and bloats up the right hypochondrium, but belching in these cases is seldom marked as it usually fails to relieve.

Chronic Appendicitis.—In many cases of chronic disease of the appendix there is apt to be complaint of epigastric distress and of gas in the stomach. The distress is often located above the navel and the gas is inferred from the sense of discomfort and rumbling in the bowels. There is no consistent history of belching as in the cases of peptic ulcer. Flatulence is ordinarily complained of and gas passed *per anum*.

Constipation.—In the various forms of constipation there is a similar complaint of gas in the stomach and bowels. The feeling of discomfort may give rise to efforts at belching. Here again we observe the tendency of the patient to attribute the abdominal uneasiness to gas, and importance may be attached to the fact of belching by these patients, when, on a little deeper consideration, they admit no real relief from belching and practise it but little.

Carcinoma.—The belching in some cases of carcinoma is unique. The coincident stasis and failing acid which sometimes are to be observed offer favorable conditions for fermentation and the actual development of gas within the stomach. This gas often has a foul odor of putrefaction and the eructations have a disagreeable taste. The belching oftentimes becomes more constant and less dependent upon epigastric discomfort. This is the picture particularly in the more advanced cases of cancer with stasis from more or less complete pyloric obstruction. In those cases which develop upon the base of ulcerative processes and those which apparently begin *de novo* there may be no complaint of gas. In certain cases of carcinoma, some of which have undoubtedly developed upon the base of ulcerative processes, there is sometimes an interval of freedom from gas which previously had been much complained of. Very possibly this represents the subsidence of acid secretion and its resulting irritation. Later on gas may again be complained of as a result of true fermentation and the irritation of putrefactive substances produced.

Stricture of the Cardia.—In stricture of the cardia, whether spasmodic or from ulceration of the nearby mucosa, there is apt to be rather characteristic complaint of gas. Again, to the patient's mind, it is all a question of gas although it is impossible to see how air or gas has anything to do with the complaints. Usually while swallowing the food seems to stick. Efforts are made to swallow the substances forcibly. These efforts are similar to those made by aerophagics. Finally a little gas is brought up and possibly the cardia opened from below admits food and relieves the spasm. The intense feeling of pressure in the chest and precordium comes to be attributed solely to the gas in the stomach.

Summary.—1. Gas in the stomach is rarely anything but swallowed air, as true fermentation takes place in the stomach only as a result of actual stasis.

2. Slight, unobtrusive eructation of gas after a full meal is not to be looked upon as a morbid phenomenon. Any slight epigastric sensation and occasional eructation are readily exaggerated in the mind of the hypochondriacal.

3. Belching is really a voluntary act, either attempted, permitted, or performed in a more or less exaggerated manner to give relief from a real or fancied distress referred to the stomach. The sensation of distress may arise from any organ adjacent to the stomach.

4. The most exaggerated form of belching results from temporary or habitual emotional states, the air not being raised from the stomach but merely gulped into the pharynx and brought up again.

5. If belching gives actual relief from distress it is fair to presume that the presence of air in the fundus of the stomach is at least a contributing factor in causing the discomfort.

6. Belching, which originally has relieved, may be carried to extremes particularly in the emotionally excitable. Such a reasonably induced aerophagia often obscures grave underlying disturbances of the circulatory system and the upper digestive tract, the belching being continued after all air has been forced from the fundus.

7. Gas is complained of in a variety of abdominal abnormalities when careful questioning shows belching is not practised. The patient presumes the distress is due to gas. This is particularly common in the discomforts associated with disease of the biliary tract, appendix, and colon.

Cancer Research.—E. F. Bashford states that one should place confidence in the experimental investigation of cancer for, if it has not yet yielded a cure, or even so much as new means of alleviating suffering, it has at any rate provided the practitioner with that definite and well-established knowledge which, if he will but lay it before his patients, must impress them with the truth that their only hope lies in the earliest possible removal of all lesions that have the remotest chance of being cancerous.—*Practitioner.*

ACUTE GONORRHEAL EPIDIDYMITIS.

REPORT OF ONE HUNDRED CASES TREATED IN THE VENEREAL CLINIC OF THE ST. LOUIS HOSPITAL DEPARTMENT.

By CHARLES M. WALSON, M.D.

ST. LOUIS, MO.

From the fact that epididymitis is a very frequent complication of gonorrhea, that it often produces sterility, that it is very painful in its acute stage, is subject to recurrences, with the possibility of spreading the infection to other individuals, this condition has a practical interest for the physician. In considering the cases of acute epididymitis occurring in the course of gonorrheal affections the causal agent would logically appear to be the gonococcus, although certain observers have held that it is due to some other organisms (staphylococci, etc.). In recent years investigations have been made on this point by F. R. Hagner,[1] Washington, D. C., and Oppenheim and Löw.[14] Hagner in operating upon 33 cases found the gonococcus in each instance where any bacteria were found, unaccompanied by other organisms. Oppenheim and Löw obtained similar results, and also established the fact that the mode of entrance of the gonococcus from the urethra to the epididymis is directly through the ejaculatory duct and vas deferens as the result of a retroperistaltic movement. The last named observer demonstrated this fact by electrically stimulating the ejaculatory duct and vas deferens of a patient recently affected with gonococci in the prostatic urethra, in whom epididymitis had not had time to occur. The result of stimulation was a vermicular movement of the vas deferens, perceptible to the hand, toward the epididymis. This was followed by an acute epididymitis, a culture from which demonstrated the presence of the gonococcus. Brönium[2] has found the gonococcus in the seminal vesicles on the side corresponding to the infected epididymis in 80 per cent. of his cases; in the other 20 per cent. leucocytes were found without the gonococcus.

The most frequent predisposing causes of epididymitis are external trauma, trauma from instrumentation (injections, prostatic massage, catheterization, etc.), lack of suspension of the scrotum, sexual intercourse, and masturbation. In the cases under consideration 10 per cent. were teamsters and attributed their condition to the jolting incident to their occupation; 25 per cent. had had some form of local treatment; 8 per cent. asserted that they had had sexual intercourse the day or night previous to the onset of the attack; 3 per cent. acknowledged that they had practised masturbation as a therapeutic measure the day previous to the attack. In questioning these patients many of them acknowledged that they had heard of this remedy, but would not confess that they had tried it.

The following data were collected in the cases coming under my observation with regard to the duration of gonorrhea prior to the onset of the symptoms of epididymitis:

Number of Cases.	Previous Existence of Gonorrhea.
6	1 week
14	2 weeks
6	3 weeks
13	4 weeks
1	5 weeks
2	6 weeks
4	7 weeks
12	8 weeks
8	9 weeks
3	10 weeks
31	More than 10 weeks

In eighty-seven cases of this series the epididymitis had existed one week or less when the patient applied for treatment. In the remaining 13 cases it had been present for a longer period. The discharge was found present at the first visit in 15 cases and had ceased in 50 cases.

The glass tests revealed the following facts: First glass was cloudy in 10 cases; both glasses were cloudy in 37 cases; both glasses were clear in 11 cases; shreds were present in 30 cases. In those cases in which both urines were clear digital examination per rectum revealed the fact that the seminal vesicles were easily palpable in 9 cases, which leads me to believe that at least in these cases the infection of the epididymis originated from the vesicles. In 12 cases it was a recurrent attack. It is to be regretted that complete data are not in hand with respect to these 12 cases, as it would be interesting to know what percentage of them were complicated by a seminal vesiculitis. It was found on examining the history of these cases that for the most part the onset was rather sudden. Premonitory symptoms, if present, were of short duration (usually only a few hours), and consisted mostly of a vague sensation of uneasiness in the affected region.

According to Jacobson, acute hydrocele is a complication in 33 per cent. of the cases. In Hagner's[1] cases 62 per cent. had hydrocele. In 20 per cent. of the cases in this series fluid was found in the tunica vaginalis. It is probable that fluid was present in a much higher percentage, but as aspiration was practised only for relief of pain, this point was not exactly determined. It is worthy of note that of the 20 patients on whom aspiration was practised all but three reported the following day with a very marked diminution in pain. As regards situation, 47 cases were on the right side, and 45 on the left side. In six cases both epididymies became involved some time during the course of their gonorrhea. In two cases there was a double simultaneous epididymitis. This last occurrence (namely, double simultaneous epididymitis) is of such extremely rare occurrence that Fournier[3] reports that he had never seen a case, while Keyes[4] has observed it only twice.

Among the sequelæ of epididymitis, sterility is the most to be feared. Benzler's[5] investigations in the German army show that of those having had gonorrhea without epididymitis 10.5 per cent. were childless. Those childless with unilateral epididymitis were 23.4 per cent., while of those having had double epididymitis 41.7 per cent. were without children. Kocher found that out of 28 cases of double epididymitis in 21 there was a complete absence of spermatozoa. The location of the inflammatory process has much to do with the production of sterility. Inasmuch as in the vicinity of the head of the epididymis the canals are more numerous than in the body or tail, the inflammatory process in the former portion is less likely to produce total occlusion of all the canals than in the latter location. Burnett[6] says in many cases sterility is obviated by a gradual absorption of the exudate left after the inflammation, but this he admits requires a long time. Keyes[4] makes the interesting suggestion that the more liable an indi-

vidual is to relapses the less likely he is to become sterile. Epididymitis is said by certain observers to be a predisposing cause to tuberculosis of the testicle. Velpeau, Kocher, Finger, and Keyes have reported fatal cases of epididymitis; this result being brought about by a secondary peritonitis.

In dealing with an attack of acute gonorrheal urethritis the surgeon should not lose sight of the fact of its most frequent complication and should exercise every effort to maintain the best possible hygiene of the urethra. To this end the urine should be kept bland and nonirritating by careful dieting and medicinal agents if necessary. As a general prophylatic measure the patients should wear a closefitting, comfortable suspensory. If the patient is a teamster or is engaged in any work such as would render him liable to jolting or sudden jars, he should be advised, at least temporarily, to escape this by a change of occupation. The danger of sexual excitement being so manifest in gonorrhea he should be cautioned to abstain absolutely from sexual intercourse or from masturbation, if addicted to the habit. All instrumentation is to be avoided in acute urethritis. Local treatment should be limited to mild antiseptic irrigations in cases of acute anterior urethritis, and at the first indication of a posterior involvement resort should be head to daily posterior irrigations.

Since the majority of cases seen in this series were wage earners depending upon their daily exertion for a livelihood, and would not consent to a period of rest in bed, it was found desirable to devise, if possible, a method whereby the patient could continue his work while undergoing treatment; the indications being to relieve pain, combat the infection, and the prevention of sterility. With ambulatory patients the first indication was met by the application to the scrotum of one of the preparations of menthol, methyl salicylate, and lanolin, which are on the market under different trade names. Such a preparation after producing a burning sensation for a few moments may be expected to produce marked relief for from five to eight hours, after which time the application should be repeated. In the cases reported it afforded excellent results in 60 per cent. of the cases. If the patient is not already supplied with a suspensory he should be instructed to procure one immediately. If pain still persists after the second or third day of this treatment examination with transmitted light will usually reveal the presence of fluid in the tunica vaginalis. In such cases aspiration is indicated. This operation will result in the removal of from a few drops to two ounces or more of fluid. In the twenty cases aspirated with three exceptions pain practically ceased after resorting to the operation. This procedure was recommended by Pirogoff,[7] and later by H. Smith,[8] who punctured the epididymis in a thousand cases and reported good results. I have recently punctured a case in which other measures had not relieved the severe pain of a week's duration, and in which no fluid was demonstrable. No serum was found and yet the patient was given immediate relief. Just how this is to be explained is a matter of some doubt, but it would appear probable that the needle punctured the epididymis or vas, permitting drainage through the puncture into the tunica vaginalis, thereby relieving the tension. As the acute condition subsides resolution may be hastened by certain local measures, which depend for their efficacy upon pressure exerted on the affected organ. Of these perhaps the most frequently employed is strapping the testicle. Chetwood[9] has devised a rubber bandage about 10 cm. wide by 15 cm. long, equipped with an adhesive strip, which is applied to the testicle as tightly as can be worn with comfort. This should be tightened daily. E. Ballinger[10] devised a pneumatic ring to be applied about the affected testicle, thereby producing compression. After the employment of these measures, supplemented by hot applications and gentle massage, the induration and thickening of the epididymis can usually be greatly reduced.

In the acute cases where the symptoms are not relieved by the measures suggested I believe the Hagner[1] operation, which consists in an incision into the epididymis for the purpose of establishing drainage, is indicated. Hagner[1] in reporting his 33 cases finds the result of this procedure very gratifying. In these cases where there are distended vesicle and a recurrent epididymitis resort should be made either to the Belfield[11] or Fuller[12] operation; the former being a vasotomy and the latter a seminal vesiculotomy. The results reported from the use of vaccine treatment in acute epididymitis are very contradictory, and up to the present time it is impossible to draw a definite conclusion as to their efficiency. R. F. Oneil[13] has presented an excellent analysis of the work in this direction.

After all symptoms have subsided and the evidences of gonorrhea have passed, and resolution seems at an end, the procreative ability of the pationt should be investigated. If no spermatozoa can be found after a number of examinations, an epididymoorchostomy or an epididymovasostomy is indicated with a view of reestablishing a patulous canal.

MENTAL SUGGESTION AS A SUBSTITUTE FOR ANESTHETICS IN THE REMOVAL OF TONSILS AND ADENOIDS FROM CHILDREN.*

By F. D. GULLIVER, M.D.,
NEW YORK.

Having in mind the large number of reported cases of sudden death occurring as a result of the removal of adenoids and tonsils from children, and believing that the majority of these fatalities are the result of the administration of the general anesthetics, ether and chloroform, I set out last February to try

*Read before the Valentine Mott Medical Association.

to find some way which would obviate the danger of death in operating on these cases in public dispensaries.

Before going further, let us consider briefly the various measures adopted by the different institutions of this city for the removal of these growths. First, in large hospitals, for example, the New York Eye and Ear Infirmary and the Manhattan Nose and Throat Hospital, the operation for the removal of tonsils and adenoids is considered as important as a major operation, and the preparation and care of the patient are regulated accordingly. I believe ether is the anesthetic used in the majority of cases in these institutions. However, in the other hospitals, especially in the out-patient departments, the importance of these cases seems to have been made light of. Indeed, in some dispensaries as many as from ten to twenty children are given an anesthetic and operated on during the ordinary clinic hours, and sent home almost immediately after the operation. I believe it is needless to remind you of the dangers attendant upon, and the complications which may follow, this method of procedure.

In still other clinics, the unsuspecting child is grabbed and held in subjection by a strong orderly and remains helplessly, yet intensely alive, to each step of the operation. Of course, the above procedure does away with the danger of an anesthetic, but I believe, and I think that you will agree with me, that the objections to this method are many and obvious. Personally, I consider it unjustifiably cruel. We would hardly think of proceeding in this manner in our private practice, and I know of no reason why we should employ radically different treatment on our dispensary patients. Thirdly, with the child struggling and crying, the operator is working at a disadvantage, and often does not obtain a satisfactory removal. The mental effect on the child is often harmful, especially in young girls of a precarious age. Menstruation is sometimes delayed, or the periods are thereby caused to cease. Finally, this method can hardly be called scientific.

In one or two hospitals of this city, ethyl-chloride and other anesthetics are used to produce anesthesia for these operations. I do not believe they are widely recommended, and as I narrowly escaped having a patient die as the result of the administration of one of them, I am obliged to condemn them. During the six years previous to last February, I used ether, and have never had a death result from its use. However, some of my friends who have taken every care and precaution have had deaths occur as a result of the administration of both ether and chloroform. Furthermore, frequent reports in the medical and lay press of accidental death from the use of ether, corroborate their experience.

I began to use mental suggestion as a substitute for ether in these cases at my clinic at Fordham Hospital. I presume you are all familiar with the psychology of mental suggestion. I think Professor Baldwin has given us an exceedingly clear definition. In his words: "Suggestion is a process of communication resulting in the acceptance, with conviction of the communicated proposition in the absence of logically adequate grounds for its acceptance." MacDougall's definition: "Suggestion is the abrupt entrance from without into consciousness of an idea or image, which becomes a part of the stream of thought and tends to produce the muscular and volitional effects which ordinarily follow on its presence."

It is a well-known fact that children are especially susceptible to suggestion; first, because of their lack of knowledge, second, because the superior size, strength, knowledge, and reputation of their elders tend to evoke the impulse of submission, and to throw them into the receptive attitude. Let me say in this connection that each child brought to Fordham Hospital for operation has been told, and firmly believes, that the doctor will give him something to smell of and that he will go to sleep. This being the case, when I gain their confidence and assure them absolutely that they are going to sleep, they are in an ideal mental state to accept the suggestion that follows. After the patient has been wrapped in a sheet and laid on the table with a pillow under his head I proceed by first asking the child its name and where he lives. After assuring him and gaining his confidence further, holding my hands on his abdomen, I endeavor to make the child breathe deeply. Then directing him to look intently at my head mirror I sprinkle a few drops of a mixture of alcohol and compound tincture of lavender on an ordinary chloroform inhaler, and placing this gently over his nose and mouth tell him to smell of it and he will immediately go to sleep. Next I remove the inhaler and exclaim, "Why, he is going to sleep now!" Waiting a few moments, I tap him sharply on the cheek and exclaim suddenly, "Now you are sound asleep! You will hear me talking while you sleep, but you will not wake up until you get home," naming his address, street, and number. Then I say, "Open your mouth," after which I insert a mouth gag. The assistant holds the child's head suspended over the edge of the table while I remove the tonsils and adenoids. Then the patient is turned over so as to allow the blood to escape from the mouth. Very often the child utters a cry while the growths are being cut, in which case I slap him on the cheek, assure him that he is all right and tell him not to cry while he is asleep. As soon as the bleeding begins to stop the child is carried to a bed in an adjoining room where he sleeps until I awaken him, when it is time for him to go home. Children usually sleep soundly after the operation, and I presume that this sleep approaches hypnosis. When I ask them on their awakening whether they have been hurt they reply, "A little bit" or "Not at all."

I have operated on about 200 of these cases in children over four years of age and have been successful in 80 per cent. with this method. In children under four years it is hard to get their attention and in many of these I have to resort to ether.

I have already pointed out to you the obvious defects of the use of ether, chloroform, and the like. I have shown you that the other method, that of forcibly holding the child, is brutal. Let us compare them with suggestion. I do not recommend that suggestion should take the place of general anesthetics when operating for the removal of these growths in institutions in which sufficient importance is attached to such cases as to afford the surgeon proper facilities for their treatment. I must, however, say that I have found suggestion of great practical value in removing tonsils and adenoids of children in an out-patient department of a general hospital. By its use I have avoided the danger which attends the administration of a general anesthetic in a public dispensary to children, and then sending them to their homes immediately after the operation.

THE SERUM DIAGNOSIS OF PREGNANCY.

IN 1908 Brieger and Trebing published the results of their observations on the antitryptic power of human blood serum. This property, which has since been alluded to as the Brieger reaction, was investigated by its discoverers particularly with reference to its increase in cases of cancer. Their observations have been confirmed and extended by other investigators, among whom Bergmann and Meyer have accorded to this reaction a definite clinical value. In 1909 Graefenberg noted an increased antitryptic power of the maternal blood during pregnancy and attributed this increase to the reaction of the organism to a tryptic influence exerted by the surface of the ovum. In the same year Thaler investigated the antitryptic power of the blood in various diseases of the puerperium, while von der Heide and Krösing extended these studies to the entire field of gynecology. It has remained for E. Rosenthal, who announces his results in the *Zeitschrift für klinische Medizin*, Volume 72, Nos. 5 and 6, to evolve a practical method of determining the antitryptic coefficient, and of utilizing the latter in the differentiation of the gravid from the non-gravid condition, and also from certain pathological manifestations.

The cause of the antiproteolytic power of the blood serum is attributed to an increased concentration of the latter in the products of protein metabolism, which increase tends to inhibit, according to certain well-defined laws governing the reversibility of enzyme action, the further progress of proteolysis. In view of the increased protein metabolism arising in pregnancy, one can readily understand why the latter should be accompanied by an increased antitryptic power of the blood serum. In fact, as Rosenthal has shown, the blood serum of pregnant women has an antitryptic power which is from two to three times as strong as that of normal serum.

Of the various methods that have been devised for the determination of the antitryptic power of the blood serum, Rosenthal regards the Fuld method as the most practical and accurate. The details of this method need not be described in this place; it will suffice to mention that its essentials consist in the determination of the effect of the blood serum upon definite admixtures of solutions of trypsin and casein. The entire reaction, which may be carried out in thirty minutes, requires four sets of observation, as follows: 1, the titration of the "system" without the addition of serum; 2, the determination of the antitryptic power of a normal serum; 3, the determination of the antitryptic power of the serum in question; and 4, the determination of the antitryptic power of a serum obtained from an individual known to be pregnant. This reaction is not a specific one: it merely goes hand in hand with the increased albuminous metabolism accompanying pregnancy. The reaction occurs also for this reason in cases of nephritis, Graves' disease, and carcinoma; hence in a female suffering from any one of these diseases the diagnosis of pregnancy by means of the above method would be impossible.

Rosenthal tested this method in 120 instances, of which 50 were cases of pregnancy; the remainder were cases of abortion, parturition, the puerperium, and various gynecological disorders. The reaction is present from the earliest month to the end of pregnancy, but is strongest during the second half of the latter. It is also present during parturition and during the first two weeks of the puerperium, at the end of which time the increased antitryptic power disappears. Fever delays the disappearance of the increased reaction. Nursing has no influence on the reaction. In various gynecological disorders, such as retroflexion, endometritis, beginning salpingo-oothecitis, and fibromyomata, there is an increased reaction, but not to the extent that is found in pregnancy. In certain cases of suspected extrauterine pregnancy this suspicion was confirmed by the increased serum reaction and subsequent developments. In the event of the death of the fetus the serum reaction reaction returns to the normal.

The utility of this method of diagnosis is unquestionable, particularly in the early months of pregnancy, when the signs of this condition may be either absent or indefinite. The existence of a negative reaction enables one definitely to rule out pregnancy, while the positive reaction, occurring in a woman free from nephritis, Graves' disease, or cancer, is an indication, in greatest probability, of pregnancy. In nursing women, in whom the diagnosis of pregnancy, owing to the occasional appearance of menstruation followed by the usual amenorrhea, is frequently a most difficult one, the serum reaction would appear to have its field of greatest usefulness, for, as already mentioned, the reaction does not occur in non-pregnant nursing women. The reaction is also of value in the cases of disease of the uterus and adnexa in which it may be desirable to determine the possible existence of pregnancy. A negative reaction enables one to rule out the latter absolutely, while a strongly positive reaction would indicate pregnancy in the differential diagnosis between this condition and retroflexion, endometritis, fibromyoma, or a beginning salpingo-oothecitis.

BILATERAL EMPYEMA.

EXPLORATORY puncture of the pleural cavity has made the diagnosis of an empyema very easy, and almost everybody is agreed, too, upon the treatment, namely, drainage of the infected cavity by means

of a thoracotomy with or without resection of a rib. The diagnosis of a bilateral purulent effusion is almost as easy, but the question of treatment presents numerous vexing problems, which are very fully considered by M. B. Fabrikant in the *Deutsche Zeitschrift für Chirurgie* (108 Band, 5-6 Heft). Should both pleural cavities be drained without fear of a bilateral pneumothorax, which, according to the usual physiological teaching, is a fatal condition? Should an aspiration of both sides, or a thoracotomy on one side and an aspiration on the other, be done instead? Should any of the procedures selected be performed simultaneously or with an interval between each interference?

Of course, only a review of the literature can give data for the solution of these problems, and such a review forms the major and most valuable part of Fabrikant's study. He has found altogether 118 cases of bilateral purulent pleuritis reported. Surprisingly enough, the mortality of the total number was 37.29 per cent.; this is low when it is remembered that unilateral empyema gives 22.4 per cent. mortality (Schede's figures). Six patients underwent a simultaneous operation on both sides of the chest, and of them only one died. In most of the other cases one pleura was drained first and a few days later the second cavity was likewise drained, the first still remaining open. This, of course, proves conclusively that bilateral pneumothorax of the degree produced by the usual operations for empyema is not a very dangerous condition. Indeed, whenever other means than a thoracotomy were employed on one side for fear of the pneumothorax, the patient seems to have had much less chance of recovery. In Fabrikant's personal case repeated aspiration of one pleural cavity was combined with resection of a rib on the other side; the patient, however, continued to have a high fever and gradually grew worse, until a similar resection was done on the other side, though a unilateral pneumothorax still existed. This procedure resulted in rapid convalescence, and when seen five years later the patient was enjoying perfect health.

In addition to supplying the information sketched above, Fabrikant's article is suggestive in still another direction. In several instances the existence of a bilateral empyema was first discovered at the autopsy table. It may be that this condition is more common than we may think, and the frequent failure of convalescence after a unilateral operation may be due to the presence of pus in the opposite pleural cavity. If the possibility is remembered and the chest explored it may lead to saving the patient's life, the probability of which outcome is so strikingly shown by the reports collected by the author.

JAUNDICE IN ACUTE TUBERCULOSIS.

Jaundice is a rare event in the initial stages of typhoid fever, being then probably due to the participation of the duodenum in the general catarrhal inflammation of the gastrointestinal tract; it appears just as rarely in the late stages of the disease. It would seem, therefore, that the presence of this symptom in an acute febrile disease which is frequently mistaken for typhoid fever should prove of great diagnostic importance. This is the opinion of Alfred S. Warthin (*International Clinics*, Twenty-first Series, Vol. I), the disease in question being acute tuberculosis, in many cases of which he has noted the occurrence of jaundice, though the usual text-book descriptions of the disease mention it as a very rare event. One patient was taken suddenly ill with high fever, chill, severe, hacking cough, and a degree of jaundice that led the attending physician to suspect yellow fever. The autopsy showed focal necrosis in the internal organs, the necrotic spots showing tubercle bacilli. There was no tubercle formation. Several similar cases showed a peculiar involvement of the liver so that the pathological diagnosis could be formulated as "bile-duct tuberculosis" in some cases and "pylophlebogenous miliary tuberculosis of the liver" in others.

Still more interesting is Warthin's observation of the occurrence of well-defined icterus in 80 per cent. of his cases of acute general miliary tuberculosis, the form of infection which most frequently leads to difficulty in differentiation from typhoid fever. Indeed, even cases of chronic tuberculosis ending in generalization of the infection, that is, in the production of miliary metastases, have shown the occurrence of jaundice in this stage of the disease. From the diagnostic standpoint, of course, this symptom is of little use at this stage, but it becomes a sign of distinct prognostic value, serving as the outward indication of the generalization of the infection and, with it, of approaching dissolution.

Race Degeneration and Eugenics.

At the Nursing and Midwifery Conference held on April 5, 6, 7, and 8 in London, the question of race degeneration and eugenics was discussed. R. Murray Leslie dealt with the different opinions and evidences of racial degeneration in Great Britain. He stated that according to his views the science formulated by Galton bids fair to strike at the roots of race degeneration and to restore the nation and race to its pristine power and vigor. The eugenist believed that heredity was far stronger than environment, that such questions as voluntary or involuntary celibacy, the age of marriage, the responsibility of lactation, and the rôle of venereal disease were of infinitely greater value than mere matters of comfort and well-being. Karl Pearson, upon whom in England the mantle of Galton has fallen, stated that the central problem of all practical eugenics was to make the well-born child a valuable economic asset. Negative eugenics would prevent all unfit persons from marrying and propagating their like, while positive eugenics dealt with all conditions and influences which make it possible for the fittest men and women to come together, so that the race may be built up from the best possible materials. Speaking of the danger of allowing people with hereditary taint of insanity to marry, Tredgold and Ettie Sayer had shown conclusively that the feeble-minded were actually more fertile than the general population. Segregation was the only means to prevent a continuance of such mental degenerates. To the eugenist, declared Pearson, the marriage of defective or diseased persons was a greater crime than the birth of illegitimate children of healthy parents.

In England the eugenic doctrine has had a great filip of late. Galton left a considerable sum of money for the propagation of the theory, and there is likewise a strong feeling throughout Great Britain that its practice might tend to stem the undoubted racial degeneration which is taking place in that country. On the other hand, the theories of eugenics and of mendelism are very difficult to put into practice. Much more definite knowledge concerning the laws of heredity is needed ere it can be stated with any assurance that eugenics will prove the panacea for many social evils which its enthusiastic supporters claim it to be.

Tuberculous Meningitis in Newly Born Infants.

Tuberculous meninigitis has long been held to be a rare disease in children under two years of age. Dr. M. Lafarcinade of the Faculty of Medicine of Paris, writing in the *Medical Press and Circular*, April 19, says that out of forty-two cases of this malady collected by him and not previously published over twenty occurred in infants under two years of age. The hemiplegic or eclamptic form is found in suckling infants, and gradually results in a state of coma. The somnolent form, however, is characterized by the four following symptoms: Progressive somnolence, ocular catalepsy, progressive emaciation, instability and irregularity of the pulse. Gradually the tendency to somnolence becomes more marked, the child is nearly always asleep, and ultimately the sleepiness culminates in deep coma. Ocular catalepsy is due to the absence of palpebral winking, to amblyopia, and the disappearance of the conjunctival reflex. The affected child sleeps with his eyes wide open but without seeing. Progressive emaciation dates from the prodromal period. As to the instability of the pulse, this consists in the fact that if the pulse of a meningitic subject is examined several times a day considerable difference will be noted. In addition to these four principal symptoms Lafarcinade says that vomiting or diarrhea is often present. However, these symptoms, instead of facilitating the diagnosis of the disease, not infrequently lead the physician astray and he is liable to diagnose gastro-enteritis. When the disease is fully developed it proceeds on its unvarying course, finally merging into coma and death. In all the cases observed by the writer the termination was fatal. From the nature of the disease the treatment is only symptomatic and necessarily ineffectual.

Psychic Causation and Treatment of Precocious Arteriosclerosis.

In the United States there is not, so far as we know, any widespread popular fear of arteriosclerosis. The public recognizes that people are ill from "hardening of the arteries" and that they often die with if not from this condition. In Austria, however, as stated by Herz, in a paper read before the Royal Imperial Society of Physicians of Vienna (*Münchener medizinische Wochenschrift*, April 4), there is an exaggerated fear of this condition, which in medical men is amounting to a phobia. The great frequency of suddenly fatal angina pectoris and cardiorenal disease seems largely responsible for this fear. Herz thinks arteriosclerosis may have undergone a change of type (he is referring naturally to precocious forms); and in response to a circular of inquiry addressed to several thousand physicians in reference to possible new casual elements, it appears that psychic trauma and excessive bodily labor are leading factors, and that a combination of the two is especially in evidence. All individuals now labor under forced pressure, due, as the author terms it, to conditions having become Americanized. There is a continued succession of psychic traumatisms with physical overstrain and as a matter of fact the causal nexus is practically that of neurasthenia. The treatment should be mainly psychic in so-called premature cases—the production of a cheerful frame of mind.

What For?

The announcement is made from Albany that Governor Dix has appointed a layman from Oswego to make an investigation of the way in which the Health Officer of the Port of New York has performed his task of safeguarding the country from imported disease. If it were not disheartening it would be ludicrous to see a lawyer from the shores of Lake Ontario investigating the administration of quarantine in New York Harbor. If there had ever been the breath of a charge against Dr. Doty there would perhaps be some excuse for the appointment of a sanitarian to determine whether the accusation was founded upon anything more solid than a longing for the salary now so well earned by this most competent and satisfactory of health officers. As it is, everybody knows that the quarantine administration in this port is as nearly perfect as human limitations permit and that there is no excuse for a change. Everyone knows, also, why there is a Democratic governor in New York today, and one need not be much of a prophet to foresee that a few political crimes, such as displacing Dr. Doty would be, will result in an eager seizing, at the next election, of the alternative which was rejected last November.

News of the Week.

Hospital Clause in Charter.—The State Charities Aid Association in a brief submitted recently to the Senate Cities Committee of New York opposes those parts of the proposed new charter for the city of New York which abolish the trustees of Bellevue and Allied Hospitals and the Board of Inebriety and create a Department of Hospitals. With the assertion that the trustees of Bellevue have succeeded in reestablishing public confidence in the institution, the association declares that it would be unwise to dismiss them. It also opposes the establishment of a department of hospitals on the ground that it would not in reality be a department of hospitals since quite as much hospital work would fall under the Department of Public Charities. Further objection is raised that the Board of Inebriety created last year has not yet had sufficient trial and that the provisions of the proposed charter mark a step backward in the care of inebriates.

Milk Show.—The city of Philadelphia has just concluded a most successful milk show, the records showing an attendance of 119,000 visitors. An exhibition was given from May 20 to 27 under the auspices of the Department of Public Health and Charities, the Milk Commission of the Philadelphia Pediatric Society, the Veterinary Department or the University of Pennsylvania, the Bureau of Municipal Research and other cooperating agencies. Addresses were delivered by local physicians and by distinguished visiting authorities. Demonstrations were given of the best methods of preparing, transporting, delivering and preserving milk.

Sea View Hospital.—The cost of completing and furnishing the new Sea View Hospital for tuberculosis patients in New York City will, it is estimated, amount to $1,149,300, making the total cost of construction about $4,000 a bed. The city has been asked to issue corporate stock to this amount in order that the large sum of money already expended may be of benefit. The Department of Health cares for its tuberculosis patients in buildings which cost for construction about $700 or $800 for each patient.

Army Medical Corps Examinations.—The Surgeon General of the Army announces the preliminary examinations for the appointment of first lieutenants in the Army Medical Corps will be held on July 10, 1911, and on September 5, 1911, at points to be hereafter designated. Full information can be obtained upon application to the "Surgeon General, United States Army, Washington, D. C." The essential requirements are that the applicant shall be a citizen of the United States, between 22 and 30 years of age, a graduate of a medical school legally authorized to confer the degree of doctor of medicine, of good moral character and habits, and of at least one year's hospital experience after graduation. There are at present sixty-one vacancies in the Medical Corps of the Army.

University of Minnesota Hospital.—The new Elliott Memorial Hospital at the University of Minnesota will, it is announced, be ready for occupancy on June 15. The hospital will be under the control of the College of Medicine and Surgery in the University.

Condensed Skimmed Milk.—A crusade against the manufacturers of condensed skimmed milk who misrepresent their product has been started by the United States Department of Agriculture. As a result of an investigation of the condensed milk situation, which has been in progress at the Bureau of Chemistry for some time, Dr. Harvey Wiley is convinced that the lives of an almost unlimited number of infants are endangered by the use of such milk, and he has recommended that certain manufacturers be prosecuted for violation of the pure food law.

Prevalence of Measles.—During the first week of May about 600 cases of measles were reported in the Borough of Manhattan, New York, while for the week ending May 20 the number had increased to 700, indicating that the spring outbreak had begun rather earlier than usual. In 1907, when the last epidemic occurred, there were 7,542 cases reported in one month, with a total for the year of 38,276, as compared with 16,622 for the previous year.

Yellow Fever on Ship.—The French steamer *Peron*, which arrived at La Guayra, Venezuela, from Colon on May 25, was reported to have eight cases of yellow fever on board. By the time the same vessel had arrived at Fort de France, Martinique, on May 29, there had been fifteen cases, two of which had terminated fatally.

Census of London.—The total population within the limits of greater London is given, as the result of the recent census, as 7,252,963, an increase of 10.20 per cent. over the population ten years ago. In the City of London proper there was a considerable decrease, but the outer ring shows an increase of 33.49 per cent., indicating that the trend of population is towards the suburbs.

Population of Ireland.—The census returns for Ireland, announced on May 26, give the island a population of 4,381,951, a decrease of 1.7 per cent. from that of ten years ago, the net decrease being 76,814. This decrease, however, is less than for any period since 1841. Among the male population the decline was 0.6 and among the female 2.8 per cent.

Death at 101.—Mrs. Hannah Van Tassel, who died at her home in Cold Spring, New York, on May 20 after a short illness, celebrated her 101st birthday last January. Her last illness was said to have been also her first serious one.

California State Homeopathic Medical Society.—The following officers were elected at the annual meeting in Pasadena on May 10: *President*, Dr. Edgar P. Bryant of San Francisco; *Vice-presidents*, Dr. W. J. Hawkes of Los Angeles and Dr. Floella Estes of Los Angeles; *Secretary*, Dr. Guy E. Manning of San Francisco; *Treasurer*, Dr. T. C. Low of Los Angeles.

Minnesota State Homeopathic Society.—At the annual meeting in St. Paul on May 11 the following officers were elected: *President*, Dr. S. T. Cobb of St. Paul; *Vice-presidents*, Dr. F. A. Williams of Slayton and Dr. L. E. Penny of St. Paul; *Secretary*, Dr. A. E. Ahrens of St. Paul; *Treasurer*, Dr. Margaret Hoch of Minneapolis.

Iowa Society of Medical Women.—The convention of this society held at Des Moines closed with the election of the following officers: *President*, Dr. Jennie Grist of Anamosa; *Vice-presidents*, Dr. Georgia Stewart of Des Moines and Dr. Jessie V. Hudson of Iowa City; *Secretary*, Dr. Lena A. Beach of Cherokee; *Treasurer*, Dr. Grace Gerger of Waterloo.

Texas Medical Association.—At the annual meeting held on May 11 and 12 at Amarillo the following officers were elected: *President*, Dr. David R. Fly of Amarillo; *Vice-presidents*, Dr. W. H. Freeman of Lockney, Dr. A. L. Linecum of El Campo and Dr. J. H. McCracken of Mineral Wells; *Trustee*, Dr. John T. Moore of Houston.

International Congress of Medicine.—The first meeting of the permanent commission of the congress was held in London on April 21 at the Royal College of Physicians, Dr. F. W. Pavy presiding. The right of representation on the permanent commission which was requested by Canada and by Poland was refused, although the executive committee was instructed to extend all the honors of the committees to these two countries. The request that Spanish and Esperanto be added to the official languages of the congress was also refused, since while the importance of Spanish was recognized it was thought undesirable to add to the official languages already adopted. Esperanto was an artificial language and was understood by so few that it would add confusion to admit it. The request from the International Federation of Dentists for admission to the congress was not granted, nor was the request for the stablishment of a section devoted to the professional interests of physicians, since it was considered wiser to maintain the purely scientific character of the congress. The proposition of the executive committee that the date of the congress be fixed for August 6 to 12, 1913, London to be the meeting place, was accepted. Information concerning the congress may be obtained from the secretary-general of the permanent commission, Prof. H. Burger, Vondelstrat, Amsterdam, Holland.

International Association of Urology.—The second congress of this association will be held in London on July 24 to 28, 1911, under the presidency of Prof. Harry Fenwick. The following subjects will be considered: 1, Phospaturia and Oxaluria; 2, The End. Results of Prostatectomies:

3, Extensive Resection of the Bladder. Applications for places on the programme should be addressed to M. C. Dr. Desnos, secrétaire général, 59 rue La Boëtie, Paris.

The American Dermatological Association.—At the thirty-fifth annual meeting of this Association, held in Boston, Mass., May 25, 26, and 27, 1911, the following officers were elected for the ensuing year: *President,* Dr. Grover William Wende of Buffalo; *Vice-President,* Dr. James Sullivan Howe of Boston; *Secretary and Treasurer,* Dr. James MacFarlane Winfield of Brooklyn; *Councillor-at-Large,* Dr. William Allen Pusey of Chicago. St. Louis was selected as the next place of meeting.

Iowa State Medical Society.—At the annual meeting held in Des Moines on May 18 and 19 the following officers were elected: *President,* Dr. L. W. Littig of Davenport; *Vice-presidents,* Dr. H. A. Leipziger of Burlington and Dr. Van Buren Knott of Sioux City; *Secretary,* Dr. V. L. Treynor of Council Bluffs; *Treasurer,* Dr. W. B. Small of Waterloo. The next meeting will be held in Burlington.

Illinois State Medical Society.—The following officers were elected at the annual meeting held in Aurora on May 17 and 18: *President,* Dr. L. H. Nickerson of Quincy; *Vice-presidents,* Dr. J. W. MacDonald of Aurora and Dr. J. A. Miller of Pittsfield; *Treasurer,* Dr. E. J. Brown of Decatur; *Secretary,* Dr. E. W. Weis of Ottawa. Springfield was chosen as the place of meeting in 1912.

Medical Legislation.—The Illinois State Legislature recently passed the bill amending the law regulating the practice of medicine, which was commented on in the MEDICAL RECORD on April 15. The amendments, which become effective on July 1, 1911, provide for a limited license to practice which may be issued to a student in a medical college and will make it possible for such a student to practice in a hospital during a fifth year of college work.

Brainerd Medical Society.—At a meeting of the society held in Lincoln, Ill., on April 27, officers for the ensuing year were elected as follows: *President,* Dr. E. P. Sloan of Bloomington; *Vice-Presidents,* Dr. C. W. Carter of Clinton, Dr. C. B. Caldwell of Lincoln, and Dr. R. A. Noble of Bloomington; *Secretary,* Dr. H. S. Oyler of Lincoln; *Treasurer,* Dr. C. C. Reed of Lincoln.

Kansas State Medical Society.—At the annual convention held in Kansas City on May 4 the following officers were elected: *President,* Dr. J. T. Axtel of Newton; *Vice-Presidents,* Dr. George M. Gray of Kansas City, Dr. H. G. Welch of Newton, and Dr. Anderson Lincoln of Kansas City; *Secretary,* Dr. C. S. Huffman of Columbus; *Treasurer,* Dr. L. H. Munn of Topeka.

Nebraska State Medical Society.—The annual meeting was held in Omaha on May 4 and 5, when the following officers were elected: *President,* Dr. A. D. Nesbitt of Tekamah; *Vice-Presidents,* Dr. V. *Lucas of North Platte, and Dr. N. T. Johnson of* Upland. The secretary, Dr. A. D. Wilkinson, and the treasurer, Dr. Von Mansfelde, hold office until next year. The next convention will be held in Lincoln.

Lewis and Clark County (Montana) Medical Association.—The annual meeting of the society was held in Helena on April 27 when the following officers were elected: *President,* Dr. Maria M. Dean of Helena; *Vice-President,* Dr. S. A. Cooney of Helena; *Secretary,* Dr. B. V. McCabe; *Treasurer,* Dr. G. W. King of Grand Rapids.

Wisconsin State Medical Society.—The annual meeting of the association will be held at Waukesha on June 7, 8, and 9. Dr. Richard C. Cabot and Dr. Joel C. Goldthwait of Boston are included among the list of speakers announced by the president of the society, Dr. Byron M. Caples.

Yellowstone Valley Medical Association.—At the annual meeting on May 3, in Billings, Mont., the following officers were elected: *President,* Dr. James Barrett; *Vice-president,* Dr. W. R. Morrison; *Secretary,* D. E. G. Balsam; *Treasurer,* Dr. Carl Schulin.

Fergus County (Montana) Medical Society.—The election of officers at the annual meeting on May 8 resulted as follows: *President,* Dr. C. C. Wallin of Lewistown; *Vice-presidents,* D. C. E. Hagen of Hedgesville and Dr. A. E. Myrick of Stanford; *Secretary-Treasurer,* Dr. J. T. Foley of Lewistown.

The Late Dr. Edward Gamaliel Janeway.—The following resolutions were passed by the Medical Society of the County of New York at a stated meeting held April 24, 1911: *Whereas:* It has pleased God to bring to a close the life of our associate and fellow member, Dr. Edward Gamaliel Janeway, on the tenth day of February, nineteen hundred and eleven; and *Whereas:* The life and career of Dr. Janeway was such in his unwearied, painstaking work, his brilliant attainments, the respect and esteem in which he was held by his colleagues and his friends, as to make him an honor to his profession and to this Society as well as to the city and State; be it *Resolved:* That we, the members of the Medical Society of the County of New York, do express our sense of loss in the death of a revered colleague who was truly a great man and a great physician; and be it further *Resolved:* That these resolutions be spread upon the minutes of the Society and published in the MEDICAL RECORD and the *New York Medical Journal.* Signed: H. SEYMOUR HOUGHTON, M.D., FREDERIC E. SONDERN, M.D., KARL M. VOGEL, M.D.

The Late Dr. Charles H. Lewis.—The following minute was adopted at a recent meeting of the Hospital Graduate Club. "Dr. Lewis became a member of the Club in November, 1887, and was the President during the year 1905. From the beginning he was most loyal in his interest and support, attending the meetings with great regularity, and contributing to its proceedings from a well stocked mind, evidencing a broad professional culture. Added to this was an honesty of purpose, an upright life, and a geniality which made him universally beloved. He was a musician of no mean order, and no estimate of his character should omit this feature of his charming personality. No one of our entire membership will be missed from our meetings more than he. Therefore be it *Resolved:* That this minute be entered in full on the records of the Club, and be it *Resolved:* That we 'mingle our sorrows at the loss of an honored and beloved associate with the greater sorrows of those nearest and dearest to him, assuring them of our tender sympathy in their affliction.' And be it *Resolved:* That a copy of this minute be sent to the family of our late colleague, and that it be published in the medical journals of our city." Signed, JAMES E. NEWCOMB, M.D., Chairman, CORNELIUS G. COAKLEY, M.D., H. SEYMOUR HOUGHTON, M.D.

Obituary Notes.—Dr. William H. Pickford of Philadelphia, Pennsylvania, a graduate of the Jefferson Medical College in the class of 1881, died at his home on May 15, aged 51 years.

Dr. Stephen Harrison Griffith of Gaffney, South Carolina, a graduate of the University of Maryland School of Medicine, Baltimore, in 1890, and a member of the South Carolina State and Cherokee County Medical Societies, died suddenly at his home on May 4, aged 44 years.

Dr. Harry H. Baker of Chicago, Illinois, a graduate of the Chicago Homeopathic Medical College in 1897, died at the home of his mother in Brooklyn, New York, of heart disease, on May 13, aged 45 years.

Dr. Francis M. Prince of Bessemer, Alabama, a graduate of the Jefferson Medical College, Philadelphia, in 1849, a member of the Alabama State and Jefferson County Medical Societies, having been the first president of the latter, and a charter member of the Southern Medical Association, the Southern Surgical and Gynecological Association and the Tri-State Medical Society, and a surgeon in the Confederate Army during the Civil War, died at his home on May 17, aged 84 years.

Dr. A. Grant Brubaker of St. Joseph, Missouri, a graduate of the University Medical College of Kansas City in 1899, died suddenly in his office on May 15 of heart disease.

Dr. John S. Poynor of Thorp Spring, Texas, a graduate of the University of Nashville, Tennessee, Medical Department in 1865, died at his home after a short illness on May 14, aged 78 years.

Dr. Harris Howey of Wapello, Iowa, a graduate of the Geneva Medical College in 1837, a veteran of the Civil War, died at his home on May 13, aged 94 years.

Dr. Stanford Emerson Chaillé, for many years dean of the Medical Department of Tulane University of Louisiana, died at his home in New Orleans on May 27, aged 82 years. Dr. Chaillé was graduated from Harvard University in 1851 and from the Medical Department of Tulane in 1853. He then became resident physician of the United States Marine Hospital at New Orleans, and later editor of the *New Orleans Medical Journal* and demonstrator in anatomy at Tulane in 1858. In 1867 he was made professor of physiology and pathological anatomy and in 1885 became dean of the Medical Department, an office which he held until 1908, when he retired with the title of professor emeritus. During the Civil War he served as surgeon in the Confederate Army of Tennessee and was the personal physician of Jefferson Davis. Dr. Chaillé was the president of the Havana Yellow Fever Commission in 1879 and a member of the College of Physicians of Philadelphia, the Medical and Chirurgical Faculty of Maryland, the Academy of Sciences of Havana, the Louisiana Pharmaceutical Association, the American Public Health Association, the American Medical Association and the Louisiana State and Orleans County Medical Societies.

Dr. Henry Clay Angell, for twenty years professor of ophthalomology in the Boston University Medical College, died at his home on May 27, aged 81 years. Dr. Angell was graduated from the Hahnemann Medical College of Philadelphia in 1853, and after three years of study in Vienna began the practice of his profession in Boston. He was greatly interested in music, and in 1882 was president of the Philharmonic Society of Boston.

Correspondence.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

GOVERNMENT INSURANCE SCHEME—ORAL SEPSIS—606 IN CONGENITAL DISEASE—ALBUMINURIA—RAT PLAGUE—PHTHISIS IN SOUTH AFRICA—OBITUARY.

London, May 12, 1911.

The State Insurance scheme was received at first with approval by most parties. It was, in fact, too extensive and too complicated to encourage criticism until time had allowed its provisions to be grasped. Already, however, various doubts are being expressed and in some quarters opposition will evidently be made. This is quite as much so in medical as in other circles—probably more so, for the general practitioner has a rather close experience of clubs, friendly societies, parochial authorities, and so on. He knows what 4s. a year means and feels that if the state undertakes to provide free attendance the patients of that class will be more exacting than ever. A club on such terms, I am assured, cannot yield a living profit, unless so large that no other practice can be done and a motor kept to carry the doctor round with speed. Hospital managers do not look on the scheme with favor. It would tend to increase patients and decrease funds. Employers compelled to pay to the state insurance may not be such generous subscribers to hospitals as they have hitherto been. Another objection is to the new health committees proposed. There is already too much overlapping of health authorities. We have county councils and their committees, district and rural councils, guardians, friendly societies, charity committees, hospitals, dispensaries, and other bodies, besides medical officers of health. What need then for another authority? It is urged that an additional body can find nothing to do unless to interfere with the smooth working of those in existence by assuming a position which will not be admitted. Perhaps the local government board is less active than it might be, but at all events it works through the recognized authorities and will not permit a new committee to assume its powers.

Another point that gives pause to well-wishers of the plan is the proposal to build and maintain sanatoriums. Too much money has already been spent on such buildings and many are asking whether they are not as much homes for germs as for patients. The open-air treatment for which they were designed cannot be carried out in them in perfection because many parts in these huge structures cannot be continually flooded with fresh air.

The dangers of oral sepsis have for a long time occupied the attention of doctors and dentists. Many, indeed, are of opinion that they have been too freely exploited. But it cannot be denied that much investigation has been carried out with valuable results. As an instance, take Mr. Goadby's Hunterian lecture, in which he dwelt on the interrelations of mouth and joint disease (summarized in my letter in the Medical Record for April 29). The importance of the subject is further shown in its being selected by the College of Surgeons for the next Jacksonian prize. At the same time so numerous are the lesions attributed to oral sepsis that there is point in the taunt that "put out your tongue" must give away to a newer formula—such as "open your mouth."

The streptobacillus isolated by Goadby in the oral secretion offers a reasonable explanation of disorders further along the alimentary canal, the continuity of the mucous membrane affording the means of access throughout. The connection with joints is not quite so simple, but the facts adduced demand the closest investigation. As to some other diseases great doubt is expressed, and it is remarked by sceptics that enthusiasts are guessing a single cause for most invalids. The subject was brought before the Odontological Section (R. S. M.) on April 24 by Dr. Knowsley Sibley in a paper claiming a connection of unhealthy teeth and gums with skin diseases. He suggested that irritation of a branch of the fifth nerve inside the mouth might be reflected on a point supplied by another branch. A second explanation might be septic absorption. To one or both of these causes he thought might often be traced acne, acne rosacea, alopecia areata, eczema, erythema, herpes, edema, seborrhea—a fairly long list—but he mentioned further some more general skin eruptions due to septic absorption; *e.g.* erythematous rashes, purpura hemorrhagica, furunculosis. Many cases of urticaria and even of psoriasis have been recognized as the results of gastrointestinal affections, often originating in neglected pyorrhea alveolaris. Dr. Sibley had treated some cases by vaccine from the pus obtained from the gums. He showed two such patients and the microorganisms he had found. These bacteria were streptococci, staphylococci, and a spirochete. Presence of the last named demands confirmation unless perchance it was an accidental contamination.

The effect of 606 has been tried in congenital cases. Dr. Bunch reported to the Children's Section the case of a boy of 7½ months, who had shown typhoid signs when three weeks old. In January spirochetes were detected and an intramuscular injection given. In 17 days signs had disappeared, but Wassermann reaction was still positive.

This reaction was also seen in another case, a boy of 16, who had been operated on several times for disease at the lower end of the femur and was admitted to the Glasgow Western Infirmary and injected in November in the intrascapular region and in December into the median basilic vein, and again in January. On March 6 the reaction was negative. Dr. Browning, who carried out the treatment reported to the Glasgow Medico-Chirurgical Society, remarked on the painful effects on the subcutaneous tissues in many cases and said he and Dr. Ivy Mackenzie had treated more than fifty cases by venous transfusion without any untoward side-effects. A positively reacting serum was the most delicate test of infection. Treatment should not only disperse lesions, but be continued until the reaction was converted into the permanently negative form.

The Wassermann reaction has further been observed in mental deficiency by Drs. E. B. Smith and A. W. G. Woodforde, who think it important to recognize the underlying cause with a view to treatment of the parents to prevent the birth of other infected children. The mothers, in their cases, showed a negative reaction which they cannot explain, but suggest possibly the mother need not be infected in order to transmit infection; or, more probably, the reaction itself is not infallible; the factors which govern its presence or absence not being understood.

Referring to the debate on cyclic albuminuria I sent you so full a report last week that there is little to add, but by way of completion I will quote some other speakers. Mr. Clement Lucas said that out of a number of bank clerks he had examined he found 10 per cent. passing albumin. Dr. West refers to the grouping he made some years ago, prerenal, renal, and postrenal. The last is simply accidental contamination. As this is easier to exclude in males they are mostly used in statistics, but if females were included functional albuminuria would be equally common. The general curve of pregnancy was at the lowest about the age of 25, therefore adolescent cases had disappeared while insurance statistics would then begin. Diagnosis depended on whether there was evidence of renal disease. Clear history of past acute nephritis generally indicated that some disease of kidney remained. But necropsis proved that patches of degenerative lesions might be present and yet compatible with perfect health. Dr. Nestor Tirard said it seemed that different types had been spoken of in the discussion and that the main thing was diagnosis. Dr. Parkes Weber said in insurance practice he had never heard of adolescent cases giving bad results. Dr. Gossage emphasized that many cases were very transient, often only appearing once for a short time. Dr. Mitchell Bruce found that of thirteen typical cases, ten of the patients were alive and well after intervals of from eleven to thirty-one years. Not one of these survivors was out of health. As a result of his experience, the speaker concluded that the occurrence of such cases should be regarded merely as the temporary consequence of some innocent disturbance of health.

The question whether a recurrence of rat plague may take place this year in East Suffolk is occupying the attention of the local health authorities. They seem to have done all they could in the outbreak last winter, and the medical officer appointed *pro tem.* to organize a campaign against rats has issued a report of the work done. He considers surrounding the corn ricks with wire netting until threshing is finished a most important thing, and the country people should be encouraged to wage war in every way on the rodents. Of poisons he prefers barium carbonate.

From Cape Town grave news has arrived this week in reference to the prevalence of phthisis in South Africa. A committee proposing to establish an order of nurses as a memorial to Edward VII has reported to General Botha that the disease is spreading widely, and it is hoped the government will take steps accordingly.

Dr. Thomas Ligertwood, C.B., M.D., R.A.M.C., late physician to the Royal Hospital, Chelsea, died on the 10th inst., aged 81. He was an Aberdeen graduate, M.B., 1851, when he entered the army. He served in the Crimea and was present at the battles of Alma and Inkerman and the assault on the Radan. He received the medal and three clasps, the Turkish medal, the Legion of Honor, and C.B. He proceeded to M.D. and F.R.C.S., Ed. He retired in 1869.

Dr. John Tatham Thompson, Consulting Ophthalmic Surgeon to Cardiff Infirmary, died on April 28 of malignant gastric disease, aged 52. He was appointed to the special department on its formation in 1887. He was an Edinburgh graduate, M.B. and C.M. He contributed to the Ophthalmological Society (of which he became V. P.) various papers.

SANITATION IN AUSTRALIA.

(From Our Philippine Correspondent.)

SYDNEY, AUSTRALIA, March 25, 1911.

THERE is probably no civilized country of which there is so little known by the outside world as of Australia, and this in spite of the fact that nowhere does one find more carefully compiled data and statistics, printed in convenient form and available to all who may want them. It is, therefore, an agreeable surprise to find health conditions better than in any known country of the globe, if the extraordinarily low death rate of 10.95 per thousand per annum may be accepted as an index.

Much has been said and written in other parts of the world about measures to stamp out tuberculosis. Less of this has probably been done in Australia than elsewhere, but in no other country has so much practicable progress been made. The death rate from tuberculosis has been steadily declining during the past twenty-five years and now is less than 9 per cent. of the total deaths, which is a lower percentage than any published by any other country which compiles its statistics in an equally reliable manner. It may be of interest to mention the measures which were enforced and which are considered by Australian authorities to have a bearing upon this satisfactory condition of affairs. These are all the more noteworthy when it is remembered that in 1885 over 16 per cent. of the total deaths were due to tuberculosis in New South Wales.

In 1881 a Board of Health was organized in New South Wales, to which considerable powers were given to combat disease. From the time the board brought the provisions of this law into force there has been a rapid decline in the tuberculosis death rate. In 1886 a Dairies Supervison Act was passed. It required that all dairymen and milk vendors must be registered, the dairies kept in a sanitary condition, and that any person working in a dairy must be reported to the Board of Health immediately if he was suffering from an infectious disease. The enforcement of this act was followed by a marked reduction in the infant mortality. The rate for the latter for the years 1883 to 1886 was 81.6 per cent. This steadily declined, and for the years 1905 to 1908 it reached 25.9 per cent.

In 1892 the Diseased Animals Act was passed, which prohibited the sale of diseased animals and authorized the condemning and destruction of meat which was unsound.

In New South Wales the notification of cases of pulmonary and throat tuberculosis has been compulsory for over ten years. The walls and ceilings of houses in which cases occur are sprayed with a solution of formalin and the floors are washed with a solution of corrosive sublimate.

The effectiveness of the educational campaign is well shown by the fact that open air sleeping is more general than in any other country. There is scarcely a dwelling house constructed nowadays in Australia, even a laborer's cottage, which is not provided with a suitable veranda for outdoor sleeping. There is very little expectorating on the sidewalks or other public places. Ordinances to prevent the contamination of milk and other foodstuffs are well observed. In shops where fresh meat is offered for sale it is customary to find sheets of water running over the front windows and walls for the purpose of catching dust. All large cities like Sydney (population 700,000), Melbourne (population 600,000), Adelaide, and others, have tuberculosis sanatoria and also a large number of beds for chronic cases. The Greenvale Sanatorium near Melbourne will compare favorably with similar institutions in Europe or America. There are also many private sanatoria. Most gratifying progress has been made in isolating chronic and more particularly open cases of tuberculosis. In New South Wales, Victoria, and South Australia it is estimated that at least 50 per cent. of these cases have been placed in hospitals and a good proportion of the remainder under supervision. The health officials believe that only a few years will elapse before every case of pulmonary and throat tuberculosis will be under such control as to reduce the danger of transmitting the infection to a minimum.

The advaced state of the tuberculosis campaign in Australia may be judged by some of the following recommendations which were made by a conference of the principal medical officers of the Commonwealth, consisting of J. Ashburton Thompson for New South Wales, B. Burnett Ham for Victoria, W. Ramsay Smith for South Australia, J. W. Hope for Western Australia, and J. S. Purdy for Tasmania, held in Melbourne on March 8 last: "Legal power to regulate the home management of consumptives; legal power to remove dangerous or infective consumptives into segregation; legal power to detain such consumptives in segregation; legal power to examine medically contacts and housemates of consumptives; financial assistance to the wives and families of necessitous consumptives admitted to hospitals or sanatoria." In Australia legislatures usually act favorably upon the recommendations made by their responsible medical men, so that it is quite probable that the above recommendation will soon be enacted into law. The conference stated that forcible segregation was necessary for "the small number of persons who persistently decline to take the precautions enjoined upon them for the safety of others," and "to the somewhat larger number of persons whose circumstances, either of poverty or of advanced illness combined with small means, render observance of the necessary precautions by them physically impossible. This form of control should be applicable not merely to persons in dwellings, institutions, and the like places, but also to those frequenting workshops and places of public resort."

The conference estimated that the accommodation necessary for advanced cases would require a number of beds equal to a minimum of 25 per cent. of the average number of annual deaths in the preceding three years.

In South Australia the head of the Health Department, W. Ramsay Smith, and M. J. R. Wilton have worked out a very practical mortality curve for phthisis, by which the number of living cases of this form of tuberculosis can be readily estimated. Briefly, it may be summarized in the words of Mr. Wilton: "At any time the number of those who will die in the next month is one-twelfth of the original number who are yet alive." In other words, the total number of annual deaths among phthisis cases represents the number of cases alive at any given time.

From the foregoing facts and figures it will be evident that tuberculosis is rapidly decreasing in Australia and that if the health officials are given a free hand there is every prospect that the disease may be entirely eradicated from at least one country. Aside from the great humanitarian value, such

a result would be of tremendous economic worth to Australia on account of its vast fertile areas and its small population, but greater still would be the educational impetus which such a result would give the remaining countries of the world, which, with such an example before them, could scarcely help but strive for similar results.

A Case of Progressive Muscular Atrophy, Charcot-Marie-Tooth Type. F. J. Farnell.
Hemorrhagic Disease of the Newborn; Report of Two Cases in One Family. O. V. Wells.

Meningitis in Infancy.—J. L. Morse states that 75 per cent. of the cases of tuberculous meningitis occur during the first five years of life, and when cerebrospinal meningitis is not epidemic at least 70 per cent. of the cases of meningitis in infancy are tuberculous. The diagnosis between meningitis and nervous symptoms due to cerebral irritation is usually easy when the fontanelle is open. The fontanelle is almost invariably bulging when there is meningitis. In the vast majority of cases a positive diagnosis can only be made by lumbar puncture. Most of the types of cerebrospinal meningitis seen in adults occur in infancy. The following types are distinguishable: (1) the malignant or hyperacute; (2) the ordinary; (3) the mild or abortive; (4) the intermittent, and (5) the chronic. The prognosis of cerebrospinal meningitis in infancy before the introduction of the serum treatment was practically hopeless, the mortality being between 85 per cent. and 100 per cent. This has been materially changed, however, by the serum treatment. Flexner and Jobling, for example, report a mortality of 19 in 44 cases, or only 43 per cent. Pneumococcus meningitis is especially common in the early months of infancy and its symptomatology is similar to that of the cerebrospinal and influenzal varieties. Influenzal meningitis resembles cerebrospinal more than it does tuberculous meningitis.

Rupture of Supraspinatus Tendon.—E. A. Codman reports two cases of complete rupture of the supraspinatus tendon on which he operated, and in both of which he was able not only to demonstrate the existence of the anatomical lesion, but succeeded by suturing the tendon to the tuberosity in bringing about complete restoration of the function of abduction.

Intussusception in Children.—J. H. Young states that the differential diagnosis practically narrows down to those diseases which show blood in the stools. Excluding local causes of bleeding and the hemorrhagic diseases, there are only infectious and fermental diarrhea left to consider. Both have temperature, which is absent in intussusception in the early stages; neither has colicky pain, and the stools always show fecal matter mixed with the blood and mucus. Appendicitis may show the presence of a tumor, but it is usually less distinct and not movable, as is the tumor in intussusception, and there are fever, leucocytosis, and the absence of blood in the stools. Of the other causes of intestinal obstruction nothing need be said; treatment is the same.

Treatment of Intussusception in Children.—W. E. Ladd concludes that intussusception is a very fatal disease, that the mortality of irrigation and palliative treatment is high (about 70 per cent. at least); that the mortality of surgical treatment is about 50 per cent. better than that of irrigation; that the way to reduce the still high operative mortality is to operate early and not after exhausting the patient by attempted palliation and delay, but as soon as the diagnosis is made.

Progressive Muscular Atrophy.—F. J. Farnell reports a case in which the patient's first symptom of a neurological disorder was stiffness and numbness in her hands followed four months later by the development of a typical *main en griffe*. In less than a year her gait became that of the steppage type. During the ensuing three years atrophy of the proximal portion of the forearms and hands and the lower third of her legs, assuming the spindle shape, fibrillary tremors, reduction in reflexes, and both quantitative and qualitative changes in the electrical response were manifested.

Hemorrhagic Disease of the Newborn.—O. V. Wells reports two cases of this condition occurring in one family. The first child died from epistaxis that had continued for twelve hours. The second child had umbilical hemorrhage, ecchymoses, and hematoma; it was cured by means of injections of fresh rabbit serum.

Causes of Constipation. S. Floersheim.
Removal of the Third Digital Phalanx with Formation of a New Joint. E. Beck.

Aneurysm of Aortic Arch.—J. Tyson reports a case of this condition in which the treatment by means of wiring was resorted to. At autopsy it was found that the wire passed from the aneurysm through the aortic orifice into the left ventricle. The author favors wiring in cases where the aneurysm is easily accessible, because of the relief to pain afforded, if for no other reason. The essential accessibility in a given case is secured by the proximity of the sac to the surface.

Facial Expression and the Eyes.—G. T. Stevens states that physical health, intellectual force, and beauty of expression are all favored by the perfect equilibrium of the motor muscles of the eyes and the correct positions of the ocular meridians, of which orthophoria without declinations constitutes the type.

Certain Lesions of the Lymph Nodes.—D. Symmers states that primary disseminated epithelioid tuberculosis of the lymph nodes, while rare, is by no means unknown. Its occurrence as an epiphenomenon in status lymphaticus, however, appears not to have been recorded. The histological changes in Hodgkin's disease resolve themselves into three stages, the first of which is characterized by focal hyperplasia of lymphoid cells and is succeeded, among other features, by the formation of multinucleated giant cells and interstitial connective tissue overgrowth. Although the lesion may not progress beyond this granulomatous stage, cases occur in which the connective tissue stroma undergoes such extensive hyaline metamorphosis that the cellular details are obscured and the histological individuality of the process is established only with difficulty. This transformation would appear to represent an attempt at healing. A type of Hodgkin's disease exists, either primarily in the cervical region, or in the thorax, in which the growth may invade surrounding structures and initiate secondary nodules in distant parts.

Manual Treatment of Ulcers.—E. F. Cyriax describes the manual treatment of simple inflammatory ulcers, which treatment consists of local manipulations on and around the ulcer, local manipulations on the affected limb or part of the body, and general manipulations.

Pick's Syndrome.—E. E. Cornwall, in reporting a case illustrating this condition, states that the signs and symptoms which essentially constitute Pick's syndrome

are: enlargement of the liver with obstinately recurring ascites, but without jaundice and without signs of cardiac abnormality, in a patient who gives a previous history of pericarditis. Pick believes that the latent pericarditis disturbs the circulation, thereby producing hepatic engorgement and also connective tissue hyperplasia which interferes with the ramifications of the portal vein and thus brings about the ascites. He calls this pathological complex pericarditic pseudocirrhosis of the liver.

Training for Public Health Work.—A. E. Shipley discusses the lines along which physicians and nurses may be developed for taking an effective part in public health work.

Constipation.—S. Floersheim states that among the unknown causes of constipation are those included under heredity. Among the known causes are the habit of taking laxatives; a neglected diarrhea causing pathological changes in the glandular or muscular structures of the intestines; chronic dilatation of either a portion or the whole length of the large intestine; spasmodic contractions of the gut due to reflex neuroses; deficiency of the acid secretion in the stomach; and, finally, a hypochlorhydria or an achlorhydria. Diet is a most important factor in the production of constipation.

Removal of Phalanx.—E. Beck reports a case of the removal of the median phalanx of the index finger in a girl six years old. The fingers had been smashed while the child was trying to close the front door. A practically new joint was formed as the result of the contact of the tissues.

Cranial Neuritis and Salvarsan.—J. F. Schamberg concludes that inflammation of the optic, auditory, and other cranial nerves has developed in a minute percentage of cases after the use of salvarsan in syphilis. The same complications may occur spontaneously or after the use of mercury. Whether the incidence of such neuritic complications is larger after salvarsan than after mercury is a mooted question, on which foreign specialists are not agreed. These inflammations have occurred almost exclusively in cases of recent syphilis. They appear to have occurred exclusively after intramuscular and subcutaneous injections and not after intravenous administration of the drug. Optic and auditory neuritis have in many instances cleared up under a second dose of salvarsan or under mercury and the iodides. Most of the cases of neuritis have occurred two to three months after a single injection.

Surgical Treatment of Cardiospasm.—W. Meyer reports a case of impermeable cardiospasm which may be of some practical value on account of the operative method employed. The success of the operation was due, first, to the forcible separation of both pneumogastrics from the esophagus, tearing the many tiny nerve fibers that enter it from either side, and, second, to the artificial reduction of the circumference of the dilated pouch of the esophagus by a double esophageal plication after the manner of Kader's gastrotomy. The operation was performed under differential pressure by means of the positive chamber. The patient was returned to the apparatus on account of respiratory trouble the day after the operation and left in it for almost ten hours. The author's experience in this case has led him to question the entire applicability of air-tight closure of the thorax as soon as the intrathoracic work is finished.

Cardiospasm.—J. H. Iden reports a case occurring in a boy of 18 who had always before been in good health until the sudden appearance of symptoms of choking directly after a meal. The attacks of choking became more frequent until finally swallowing became almost impossible. The patient was operated on by gastrostomy according to the Witzel method and the cardiac orifice dilated by the insertion of the intestinal clamp with the blades guarded with rubber tubing and gradually and repeatedly opened and shut. No measurement of the distance between the blades was made, but care was taken against rupture. The subsequent course of the case was favorable, the cardia being dilated every day or two for some time by a rubber bag dilator.

Treatment of Cough.—F. M. Class discusses the various measures applicable in the treatment of the cough of consumptives. Unless inordinate the early morning cough is beneficial rather than otherwise. Retching is often due to excessive pharyngeal mucus, and is to be combated by a simple gargle. Mental suggestion and breathing exercises are useful aids in the treatment of cough. A long uvula, large turbinates, adenoids, large tonsils, and ulcers of the larynx need appropriate treatment. For cough due to fever rest in bed is necessary. For cough due to a small patch of pleurisy mild counterirritation and strapping of the chest are efficacious.

Meningismus from Cervical Adenitis.—W. P. Coues reports a case of meningism from acute cervical adenitis and peritonsillar infiltration, closely simulating meningitis.

Good and Bad Corsets.—G. B. Somers describes the requisites of a good corset as follows: It is laced about the hips and holds its place independently of garters or straps. It supports the lower abdomen and reduces the hips. It has a straight front. It is only form-fitting or loose about the waist and bust. It does not diminish the waist measure. It laces from below upward by means of two or more lace strings. A bad corset exercises its greatest compression about the waist and diminishes its measure from 2 to 4 inches. It is loose about the hips and held down by garters or by the tight lacing above.

Intestinal Anastomosis.—C. E. Tennant describes a new clamp which is adapted to facilitate end-to-end intestinal anastomosis.

Meningococcus Septicemia.—A. W. Skilton reports a case of this condition in which the meningococcus was demonstrated in the blood-smear.

Venous Anastomosis.—H. E. Castle describes the operation of venovenostomy devised by H. A. L. Ryfkogel and himself in the treatment of varicose veins. Delbet's operation, which they first performed, consists of terminal implantation of the proximal end of the distal fragment of the internal saphenous vein into the side of the superficial femoral vein. Its drawback is the danger of forming a thrombus occluding the femoral vein, and to avoid this they concluded to make an end-to-end anastomosi of a branch of the superficial femoral with the internal saphenous vein. Thus the valves of the femoral vein are utilized to support the heavy column of blood which in the normal subject is supported by the valves

of the saphenous, and the lower part of the saphenous is relieved of all backward pressure from the inflow of blood into it from the superficial external pudic, superficial epigastric, superficial circumflex iliac and other smaller tributaries.

Resuscitation by Cardiac Massage.—C. H. Frazier reports a case of resuscitation by subdiaphragmatic cardiac massage in a patient in a state of collapse during operation and under artificial respiration. While the majority of cases in which this procedure has been resorted to hav been those of chloroform syncope, as in the case reported, it has been recommended when the syncope is the result of drowning or asphyxia and in cases when the suspension of function is due to simple exhaustion or injury. Perhaps the most important practical consideration is the method. Shall the heart be massaged directly through a thoracoplastic opening or shall the subdiaphragmatic route be followed? The best results seem to be obtained by the latter.

Noma in the Adult.—H. D. King states that noma in the aged does not differ materially from the disease as seen in childhood. The supposed predilection of this malady for the female sex is due alone to the fact that the female genitalia offer a more suitable field for infection. No certain and definite organism has been definitely established as the causative factor; the indictment of the long, thread-like bacillus, so frequently regarded as the cause of the disease, is on purely conjectural grounds. Infectious submaxillary angina may be the forerunner of noma, and once the gangrene arises it would be difficult, indeed, to say whether the condition was due to angina or noma. This, too, despite bacteriological observations, as it is more than probable that the two conditions could be coexistent. It is highly probable that noma is a process caused by more than one type of organism.

Chemistry of Nephritis.—H. T. Karsner finds that in the acute disease, especially in the early stage, the retention of protein products as shown by the nitrogen eliminated is very considerable. Later, however, if the amount of urine increases the nitrogen also increases and may be relatively excessive for a time, being apparently an attempt to get rid of the hitherto retained material. The sodium chloride excretion is generally parallel to the nitrogen. In both forms of chronic nephritis the nitrogen elimination is variable, sometimes retention is followed by later excessive elimination. These variations cannot at present be definitely explained. Attempts to differentiate parenchymatous and interstitial nephritis by the use of phenolsulphonephthalein have not yet been sufficiently confirmed by autopsy findings to be considered final. Naturally, the amount of urea varies with the nitrogen. Uric acid and the purins show much less variation and the creatinin is also said to vary, though that is not definitely settled. Phosphates and sulphates are retained and eliminated parallel with the nitrogen output.

Diphtheritic Conjunctivitis.—H. Friedenwald reports a case of this condition in which he thinks it probable that the eye was the primary seat of infection, as the nasal and pharyngeal symptoms came on several days after the appearance of the conjunctival disorder.

Gangrene from Carbon Monoxide Poisoning.—A. McLean reports a case of carbon monoxide poisonning resulting in gangrene of both legs.

Blood Platelets.—J. H. Wright and E. Kinnicutt describe their new method of counting the blood-platelets for clinical purposes.

Heredity and Insanity.—F. W. Mott states that hereditary predisposition is the most important factor in the production of insanity, imbecility, and epilepsy. It is the tendency to nervous and mental disease, generally speaking, which is inherited. This may be termed the neuropathic taint. Education, sanitation, and the rest, as Bateson has stated, are only the giving or withholding of opportunity for good or ill. Alcohol is a powerful coefficient, but not of itself the main cause, in the production of insanity, except in the rather infrequent cases of alcoholic dementia. Certain types of insanity may be transmitted with greater frequency than others. This has been termed similar heredity. The types are: periodic insanity (also termed "manic-depressive"), delusional insanity, and epilepsy. The general rule, however, is for a different type to appear. Mothers transmit insanity and epilepsy with much greater frequency than do fathers, and the transmission is especially to the daughters. Anticipation or antedating is the rule whereby the offspring suffers at a much earlier stage than the parent. Regression to the normal average may be by marriage into sound stocks, or by anticipation or antedating leading to congenital or adolescent mental disease terminating the perpetuation of the unsound elements of the stock. High-grade imbeciles who are not at present in any way checked in procreating owing to social conditions interfering with survival of the fittest, together with chronic drunkards, neurasthenics, and neuropaths, are continually reinforcing and providing fresh tainted stocks. Recurrent insanity owing to the fact that patients are not segregated for any length of time is probably the most potent cause of insane inheritance. Facts tend to support the opinion that the recurrent types of insanity during lucid intervals may breed a stock of potential lunatics and paupers. Nature is always striving to go back to the normal average and only relatively few of a stock are insane.

Abnormal Forms of Breathing in Angina Pectoris.—J. D. Windle reports a number of observations that have reference to a group of symptoms embracing angina pectoris, pulsus alternans, and abnormal respiratory rhythm. Usually the first and most common complaint of these patients is of breathlessness on exertion, hitherto undergone without distress. This is often associated with paroxysms of dyspnea, which occur more usually at night. The disturbance in rhythm may consist of an altered time relationship between the inspiratory and expiratory phases of the individual respiratory movements, which is normally as 3 : 4; either period may be abnormally shortened or prolonged, and so give rise to an inverted rhythm of the individual respiratory movements. Respiratory alternation of pulse is the name given to that form of pulse in which the strongest and slowest beats do not correspond with expiration. There are forms of irregularity in breathing in which periodic variations in the rate and depth of respiration are present. At times the rate of breathing rhythmically changes without marked alteration in its depth. This variation occurs while the patient is at rest, but on the least exertion breathlessness is pronounced and the rhythm becomes quite regular. Mild and pronounced forms of Cheyne-Stokes breathing may occur.

Utriculoplasty for Uterine Hemorrhage.—V. Bonney reports cases which seem to show that the operation of utriculoplasty is a legitimate alternative to hysterectomy in the treatment of intractable uterine hemorrhage due to the condition variously known as "hemorrhagic metritis."

"chronic fibrotic metritis," and other similar terms, and also that it is feasible to apply it to a uterus the seat of small multiple myomata. It would appear to be preferable to hysterectomy when the patient is still of child-bearing age, and the cervix is reasonably healthy, and especially if the patient herself objects to an enforced abolition of the menses. In the reverse of these conditions removal of the uterus is the more suitable operation—by total hysterectomy if the cervix be unhealthy, by subtotal hysterectomy in all other cases. In the event of pregnancy following utriculoplasty it would be desirable to induce the labor some weeks in advance in order to lighten the work of the uterus.

Hematocolpos.—W. B. Bell states that hematometra rarely occurs with hematocolpos, and can only be a very late complication. The non-coagulability of menstrual blood is due to the removal of fibrin ferment and fibrinogen, probably effected by the endometrium. The lactic acid present is not produced by bacteria. The calcium content of menstrual discharge is very high. The vagina is for the most part developed from the Müllerian ducts, and its lining epithelium may therefore occasionally be of a columnar type, and glands may be present.

Hidden Dangers of Appendicitis.—H. J. Paterson advocates immediate operation as soon as the diagnosis is made. He reports eight cases in none of which the patient appeared to be seriously ill. In two of them there was general peritonitis and in all the appendix was gangrenous or perforated.

Perforated Gastric Ulcer.—W. P. S. Branson and T. P. Legg report a case that presented an unusual train of symptoms. The first symptom of the series was the pain announcing perforation of a gastric ulcer. This produced the pleurisy from which the illness dated, and, to judge by the extent and density of the adhesions about the stomach, led also to a subdiaphragmatic abscess, the shrunken cavity of which was still in communication with the interior of the stomach. The pains which were the predominating feature of the malady in its later stages were neuralgic in character, apparently excited by the involvement of branches of the intercostal nerves in the cicatrix which bound the stomach to the anterior abdominal wall.

Cancer Research.—C. E. Walker describes the progress of cancer research as conducted at the Glasgow Cancer Hospital. This research is being conducted along three principal lines: the cytological investigation of malignant growths, chemical investigations, and experimental work with malignant growths occurring in animals.

Official Tariff for Medical Attendance.—G. P. Forrester describes the official scale of charges for professional services rendered by physicians and surgeons which is in existence in Germany. Its provisions are legally applicable in all cases in which a dispute as to the fee arises in the absence of any special agreement between patient and doctor.

The Etiology of Iritis. R. A. Yeld.

Functional Derangements of Nervous System.—G. E. Rennie refers to Ziehen's definition of hysteria as an abnormal accentuation of emotional activity, while neurasthenia is described as a condition of irritable weakness of the nervous system marked by a host of subjective and a few objective symptoms.

Lead Poisoning and the Race.—Sir Thomas Oliver states that quite apart from its effects upon emunctories such as the kidneys, also upon the blood-making organs and the nervous system, lead hits hard the productive powers of man and woman, but especially of woman. Lead destroys developing life by directly poisoning it, or it checks the growth of the fetus in the womb by cutting off its channels of nutrition. Females who worked in lead before marriage miscarried twice more frequently and females working in lead after their marriage miscarried three times more frequently than those engaged in ordinary housework. The worst examples of industrial disease are seen in Hungary, in which country the manufacture of cheap pottery causes unusually severe types of plumbism among the women and children. Among the few children that are born there are many examples of rickets and infantilism. Hydrocephalus and acute meningitis are common.

Granular Kidney and Its Surprises.—S. West states that granular kidney is for a long time compatible with apparent health—that is, is associated with no striking loss of energy or strength. The symptoms when present may be most misleading, and point almost anywhere else rather than to the kidney. Yet the pulse usually gives the indication if properly examined—not the pulse beats, for they may be unaltered; nor the pulse wave, for it may not be characteristic; nor the arterial tension, for this is not at all times high—but the artery itself, which is almost always markedly thickened. Among the first conditions that may arise in the course of granular kidney are acute nephritis, hematuria, epistaxis, cerebral hemorrhage, and cardiac failure. Thoracic aneurysm is a common associated condition, while pericarditis, although it develops in the later stages, is frequently insidious and is detected only on physical examination. Some of the most startling surprises arise in connection with the eye. Sometimes cachexia and asthenia suggest malignant disease and gastrointestinal symptoms are of common occurrence. Headache is the commonest complaint that brings the patient under observation. Convulsions may be the first symptom. Acute uremia, like apoplexy, is one of the most startling surprises.

Secondary Syphilitic Nephritis.—A. J. Hall and J. M. Beattie report a case of this condition in which the kidney disease began at or about the time the symptoms showed themselves, that is, within a few weeks of becoming infected. Whether syphilis was the actual or only the predisposing cause cannot be with certainty decided, but the fact that similar cases have from time to time been recorded and have completely recovered under antisyphilitic treatment suggests that the relationship between the two conditions is a close one.

Vasomotor System in Tabes.—H. Matthews states that, in addition to impairment of the cerebrospinal reflexes in tabes, there are perversions of functions in the sympathetic system. These manifest themselves as edema of the extremities, extravasations of blood, vasoconstriction, as evidenced by anemia, and coldness of the extremities, and various other peripheral vasomotor disturbances.

Congenital Aphasia.—E. McCall reports two cases of this condition in children: one, a case of word-blindness, the other, a case of word-deafness.

Vaccines in Rheumatoid Arthritis.—C. P. Ball reports five cases of this condition which were favorably influenced by the use of streptococcus vaccines.

Rise of Temperature after Exercise.—N. D. Bardswell and J. E. Chapman present records which show the rise of temperature which occurs in normal individuals as the result of exercise and which are of interest apropos of pulmonary tuberculosis in several respects. It has fre-

quently been stated that a rise of temperature following exercise is a characteristic sign of pulmonary tuberculosis, and, in fact, that the disease can be recognized by such a rise. This obviously is not the case. Again, a rise of temperature occurring in a consumptive patient after exercise is by many considered to be evidence that the patient has inoculated himself. What is termed autoinoculation may have taken place, but the fact of the temperature being raised, even to a considerable extent, is in itself no evidence of such autoinoculation. It is a fact of some interest in this respect that the consumptive in good general condition, but with well-marked physical signs and with bacilli still in his sputum, will often be found to have a lower temperature after a given amount of exercise than a healthy person who has done exactly the same work. The rise of temperature in the consumptive in such a case is not due to an autoinoculation, it is a physiological rise as a result of the exercise.

The Proscription of Glasses.—R. A. Morrell states that eyestrain is frequently a manifestation of breakdown of the general health, the treatment of which is just as important as the fitting of glasses.

Etiology of Iritis.—R. A. Yeld, in an analysis of 159 cases of iritis, notes the following causes, in the order of their importance: syphilis, rheumatism, gonorrhea, toxemia, gout, osteoarthritis, and exposure to cold.

Berliner klinische Wochenschrift.

May 1 and 8, 1911.

Syphilitic Chancre of the Scalp.—Despite the vast recorded material of extragenital chancre, Weiss can find notes of but 21 locations in the scalp during the past fourteen years. To this number he adds another case—in a nursling with multiple chancres. These, two in number, were seated close together on the occiput, and eventually became confluent with formation of a large indurated lesion. At the birth of the child both it and the parents seemed healthy, although there was a history in the mother of a mild attack of syphilis five years before, which after an inunction cure remained latent. The Wassermann reaction in the mother was but weakly positive. The spirochete was found in the chancre, but the Wassermann test was negative! The infant was but 9 weeks old and must have been infected for at least six weeks when first seen. The secondary rash appeared in due season and both primary and secondary lesions yielded promptly to injections of sublimate. The virus could not have come from the mother, and its source was quite unknown.

Bacillus Coli in the Cerebrospinal Fluid.—Hartwich gives a very brief account of a case of this finding. Patient was a man aged 42 years, admitted to a hospital for supposed acute miliary tuberculosis of the meningeal and typhoid types after typhoid and paratyphoid had been definitely excluded. The spinal fluid was examined to confirm the diagnosis of tuberculous meningitis, but instead of Koch's bacillus was found in abundance the *Bacillus coli* which responded positively to the five or more classic tests. Upon the death of the patient was found miliary tuberculosis of the lungs, kidneys, spleen, liver, and intestines; also tuberculosis of some of the cerebral vessels, and a small tuberculous tumor of the brain. From this tumor the *Bacillus coli* was obtained in pure culture. The rationale of the case should be somewhat as follows: The primary lesions were in the intestine, and from this point the *Bacillus coli* may have entered the blood along with the tubercle bacillus. The lesions in the brain followed. The tumor was of long standing, and the presence of the *Bacillus coli* in the blood-supply doubtless caused the suppuration in the outlying area. The tuberculosis of the blood-vessels of the brain would explain the sudden development of acute miliary tuberculosis, but the meningeal symptoms could only have been due to the *Bacillus coli*.

Treatment of Enuresis Nocturna.—Klotz, after alluding to the vast number of alleged remedies for this condition, expresses the conviction that the profession is not sufficiently aware of the importance of two therapeutic measures. One is psychotherapy, and especially the so-called "surprise" or "counter shock" process. This may be carried out by the cold douche or faradic brush at bed time. The child is placed naked on an infant chair or similar arrangement, and the douche directed against the anus and genitals. He or she is taken wholly by surprise. Naturally but one sitting is practicable, but this is often sufficient for a permanent cure. The treatment may be varied by beginning with a warm douche and switching suddenly to the cold one. The procedure cannot be used if the child has been previously subjected to cold water "hardening." The second resource cited by the author is based on the fact that bed wetters are usually very sound sleepers, and are correspondingly hard to rouse. The child is in a state approaching sleep-drunkenness, as shown by the fact that even after waking he may void his urine if he is not yet capable of orientation. Hence he may be waked up regularly at a definite hour and be made to urinate, until this becomes a habit. He does this automatically at last, without being actually roused from sleep. A nap in the day time makes the night sleep less profound. The child should also be discouraged from too hard work and play as these favor deep sleep.

Psychical State of the Recently Injured.—Meyer speaks of the interest manifested at present in this subject. Not much material is as yet available, and a research into the literature of the past two years brings to light only 37 cases, of which all but 3 deal with head injuries. Of this number no less than 25 presented psychical alternations, 5 being of a severe and persistent character. Two patients died, both in delirium, which developed on the second day. Before the delirium one patient was capable of orientation, while the other was incapable thereof. Subtracting the 2 fatalities and 5 severe and persistent examples, we have 18 relatively mild cases. Of this number there was disturbed orientation in all but 2. This disturbance was chiefly one of time relations. For one day and upwards patients were unable to recall the date or day of the week, respectively. The longest interval before orientation was completely recovered was two weeks, and concerned only the calendar year. Space orientation was not much disturbed, and this is also true of personality orientation. In the majority of cases the power of attention was somewhat affected, and generally speaking there was a depression of all psychical activities. Thus simple problems like subtraction were performed with difficulty. The intelligence tired very rapidly after slight exertion. This abnormal fatigue was quite characteristic, and perseveration was also common. In marked contrast with the abeyance of intellectual power was the sense of well being. The patients were often cheerful and made no complaints. Euphoria in connection with commotio cerebri has been noted by several observers. In other cases, however, there were mental depression, irritability—in short, the opposite picture. Of the original 37 cases tested 12 showed no psychical disorders.

Intermittent Dyskinesia of the Arm as a Symptom of Sclerosis of the Aortic Arch.—Bretschneider relates a case in detail from which it appeared that an arteriosclerotic man aged sixty-one suffered from paroxysms of cardiac oppression with cramp-like pains which reached from the angle of the jaw to the shoulder, and thence down the left upper extremity along the radial side to the thumb and index finger. The musculature of the entire extremity was rendered incapable of contraction

during the paroxysms. The tonus was abolished, the muscles were flaccid, voluntary motion was impossible after the first effort. The pain in the arm was associated with numbness. The diagnosis of aortic sclerosis was made as follows: There was no radial pulse in the left arm, while the pulsation of the left subclavian was less marked than that of the right. The left brachial and cubital arteries were pulseless. Aneurysm could be excluded. There was a soft systolic murmur over the aorta, and also a systolic mitral murmur. To account for the dyskinesia in the left arm the author makes free use of the teachings of Head that a pathological visceral process may be projected as a reflex to peripheral structures which lie in certain zones. In aortic disease the characteristic projection is in the third and fourth cervical and first dorsal zones, which correspond closely to the distribution in the author's case.

Appendicitis from Coprostasis.—Maier gives a brief account of a case which he believes to be of importance from the general standpoint of etiology. A girl aged fifteen was admitted to a hospital with the partial clinical picture of nonfebrile appendicitis (muscular defence over cecum, tender McBurney's point, and the appearance of a very sick patient). There were conjoined to this picture evidences of intestinal obstruction (meteorism, gas pains, scyaloucs masses in sigmoid flexure). Patient also had a dilated stomach, with diminished acidity and insufficient digestion of starch. She was put to bed and treated solely with HCl and diet. The scybalous masses were soon expelled (spontaneously?). With these simple measures, which resulted in proper assimilation of a suitable quantity of nourishment and regular evacuations, the child made a complete recovery in three weeks. The condition had come about apparently from neglect of the bowels, leading to chronic appendicitis and coprostasis. The cure was completed by an interval operation.

Muenchener medizinische Wochenschrift.

May 2 and 9, 1911.

Autoreinfection with Syphilis.—This unheard of phenomenon has been placed on record by Bering. Patient, male, aged 28. Typical indurated chancre on left side of glans five weeks after exposure. Enlarged lymphnodes. No exanthem as yet. Wassermann positive. Gray oil injections began, and chancre and enlargement of glands disappeared. Patient without symptoms or treatment for over a year. In the meantime his wife and one child had developed syphilis, the former then having condylomata of the vulva. At this time patient, who had reacted negatively to Wassermann was reinfected fourteen days after connection with his wife. A chancre, with enlarged inguinal lymphnodes, developed on the right side of the glans (the first chancre had been on the left side, scar still in evidence). The spirochete was found in the chancre, a malular eruption appeared and the Wassermann reaction was positive. Patient treated with salvarsan, symptoms all vanishing. Investigation showed that the wife had undoubtedly been contaminated from the husband's first chancre. She had given at the time a negative Wassermann. Two months later the chancre appeared at the mouth of the urethra. Patient treated with calomel injections, and appeared to have been cured. She was in the last months of pregnancy at the time and the child was healthy at birth but developed anal condylomata when a week or so old. Just a year later, the mother developed the vulval condylomata from which the husband had been reinfected. That a reinfection took place does not admit of doubt, nor can it be doubted that the patient was cured of the first attack by Hg. Quite recently all authentic cases of reinfection have been compiled by John. In all this number there seems to have been no instance of reinfection from the patient's own virus. The author's case is therefore unique, although the distinction between this and the common type is not of vital significance, for there is no reason *a priori* why a man should not become reinfected from a woman originally contaminated by himself. With the improvements in diagnosis and treatment, it might be easy to show that a couple could reinfect each other indefinitely unless both were radically cured at the same period.

Cesarean Section On the Dead.—Stern calls attention to the great antiquity of this procedure. Merely to open the abdomen and uterus of a woman already deceased for the purpose of saving her child alive is a procedure so simple as to be within the power of any layman. In the great majority of cases the child failed to survive the operation, but the percentage has steadily increased, until the zero or 1 per cent. of the former survivals has so improved that it now amounts to 50 per cent. and more. The death rate of the children is not inherent but is due chiefly to delay on one hand (the physician arriving too late) or to death of the infant just before the death of the mother from failure of oxygen in the maternal blood. If the physician is on the ground at the time, he must decide whether he has a right to operate just at the moment of the death agony. This problem will doubtless be decided negatively for the apparently impending death may not occur and the physician will never know whether the death should be laid to his door or to the disease which had led up to the fatal termination. The fetal heart beat must be controlled and if it is in evidence at the death agony it will be safe to await the inevitable death. On the other hand there are certain cases in which prompt evacuation of the uterus before the death agony may actually give the mother a chance for survival (eclampsia, heart disease with pulmonary edema).

Orthostatic Albuminuria in Tuberculosis.—Lüdke and Sturm believe that the frequent occurrence of orthostatic albuminuria in subjects with pulmonary tuberculosis is due to the irritant action of the toxin upon the kidneys. They tested 140 cases of tuberculosis comprising all stages of the disease and found that after an hour in the standing position albumin appeared in the urine of 102 patients. The percentage is greatest in the first stage and smallest in the third. This variety of albuminuria is also present at times in the so-called pretuberculosis stage, for the diagnosis of which it presents a certain value. The albumin in these cases is chiefly englobin. In cases of tuberculosis without the presence of orthostatic albuminuria, a small injection of tuberculin which stops short of causing a febrile reaction will set up the phenomenon in 50 per cent. of cases. Tubercle bacilli are not infrequently found in the urine of tuberculous subjects having orthostatic albuminuria.

Connection between the Skin and Adrenals.—Meirowsky states that the adrenals regulate and inhibit the pigment metabolism of the skin. They work upon certain albuminous cleavage products of the epidermis (tyrosin and its derivatives). In case of disturbance of this process through functional or structural disease of the adrenals the cleavage products of the epidermis are transformed by oxidases into pigment before they can be absorbed into the circulation. Thus is naturally explained the pigmentation of Addison's disease.

Fatal Pyemia Following Spermatocystitis.—Gruber relates a case of this sequence in which the staphylococcus was the peccant microorganism. The case is probably unique, although staphylococcus pyemia, originating in other portions of the male genital tract, has been recorded. The autopsy in the author's case showed inflammation of the left seminal vesicle, with metastases to the lungs, purulent pleurisy and pericarditis, and nephritis. Naturally,

the part played by gonorrhea in such cases is of prime significance, since primary suppuration from other causes in nontraumatic cases is hardly likely to develop. The patient was aged twenty-four, and recently released from military service. He had always been well. The affection began with high fever and pectoral symptoms, and from first to last the picture was one of cryptogenetic pyemia. A provisional series of diagnoses was made which referred the condition to a possible appendicitis or peritonitis. Evidences of cardiac and circulatory failure were abundant. Autopsy revealed the primary lesion in the left seminal vesicle. No gonococci were to be found, and in the absence of all evidences of the results of gonorrhea and the negative history the author is obliged to regard the infection as a primary staphylococcus lesion in the urethra of unknown character. The germs may have found their way into the prostatic urethra through the blood stream.

Plague in North China.—Schreyer calls attention to the two forms of lung plague known respectively as pneumonia and septicemia. The period of incubation is from five to seven days, the duration of the disease from twelve to twenty hours. The disease is communicated during this short period. The transmission results from the spray projected from the air passages as a result of speaking and coughing. Masks protect the wearer from contagion, as does also the turning away of the face.

Deutsche medizinische Wochenschrift.

May 11, 1911.

Cellular Anaphylaxis.—Schittenhelm and Weichardt write briefly on this subject, which is believed to underlie a hitherto overlooked series of pathological conditions. The authors have already described an enteritis anaphylactica. This was produced in dogs by sensibilizing them with egg albumin, a substance nontoxic to the animals. Upon reinjection after a considerable interval enteritis developed of a severe and hemorrhagic type. The condition extended from the pyloric half of the stomach to the anus. Nonsensibilized dogs tolerated large quantities of the albumin injections, the intestine remaining absolutely intact. According to the authors the anaphylaxis in these experiments is local and confined to the intestinal cells. The specific character is further shown by the fact that the enteritis showed areas of maximum intensity, viz.: in the upper segment of the small gut and in the lower portion of the ileum near the ileocecal valve. Hay fever may also be shown with plausibility to be a form of local cellular (epithelial) anaphylaxis which affects the conjunctiva and Schneiderian membrane. The pollen albumin of certain flowers evidently sensibilizes the epithelia of these membranes, so that repeated exposure gives rise to anaphylactic coryea and conjunctivitis. Clinically an anaphylactic enteritis in man may be produced at times as a result of excessive injection of albumin.

Medical Treatment of Gastric Hyperacidity.—Roubitschek manages this condition as follows: He gives hydrogen peroxide in ½ per cent. solution on the plan of a medicated spring cure, *i.e.* 300 c.c. are taken on a fasting stomach. After three days the acidity is tested, and if it has not fallen notably a ¾ to 1 per cent. solution is substituted. This percentage is never exceeded, as it marks the limit of tolerance. By following this plan the author obtains 80 per cent. of cures. The remainder are not only not cured, but are not benefited. The average time required for cure is fourteen days. If the condition does not return after three months' observation period the patient is regarded as cured. The diet must, of course, be regulated.

Hysterical Pseudoaphasia.—Becker relates the following case: A young man, previously free from neuropathy, and otherwise sound, was injured in a railway wreck, developing traumatic hysteroneurasthenia, with an abulic syndrome—exaggerated reflexes, tremor, tachycardia, weakness of will, indifference, fatigue on slight exertion, hypochondriacal introspection. He sustained a second accident—a fall—and several weeks later speech disorder developed suggestive of motor and sensory aphasia, and isolating him from the world. Careful analysis, however, showed that neither a motor nor a sensory aphasia was present in a typical form, the cardinal evidences of each being absent. The condition resembled much more strongly amnesic aphasia, but even the latter was excluded by absence of an essential point. If patient was unable to locate a given word, the pronouncing of the latter by another person would not aid in its recognition. By exclusion of all the forms of true aphasia, therefore, the author arrived at the diagnosis of hysterical pseudoaphasia.

Intrauterine Respiratory Movements of the Fetus.—Reifferscheid alludes to Ahlfeld's pioneer report of the discovery of fetal respiratory movements in 1888. These numbered on the average sixty-one per minute, and were remarked as a rule in the vicinity of the internal umbilicus. That these movements were of fetal origin, let alone the claim that they were respiratory in character, was a pure assumption. Others had seen these rhythmic movements without seeking to explain them offhand. Animal experiment showed that compression of the umbilical cord in a pregnant sheep appeared to set up respiratory movements in the fetus as a result of apnea. A controversy was begun between Ahlfeld and his opponents which has persisted for years, the former not recognizing the validity of the animal experiments, and holding to his belief that the respiratory movements were of purely fetal origin. The author made most elaborate experiments on a pregnant woman, which dealt with the maternal circulation and respiration, and appears to have shown beyond doubt that the fetus may exhibit true respiratory movements in utero, the rationale of which cannot yet be explained.

Hygiene of Popular Alimentation.—E. Hamaide discusses the ordinary diet of the laboring man in reference to the nutritive values of the various foods. Hazard and caprice have had too much to do with the selection of foods. The author reviews the work of Marcel Labbé on this subject. He finds that most people do not eat enough nourishing food. Others eat too much for the work that they are doing. We eat too much meat and too few vegetables and fruits. To say that meat makes strength and vegetables weakness is false. Meat is in no way necessary to the production of energy, and its excess is prejudicial to health. Albumins and mineral salts are reparative, fats are heat producers, carbohydrates are energy producers. Appetite does not measure the needs of the body. Milk should enter largely into the diet in the form of chocolate, milk soups, etc. Cheeses of all kinds are a very valuable kind of food. Eggs contain both albumin and phosphoric acid needed by the system. Meat is an excitant of the nervous system; it acts like alcohol, coffee, and tea. The author recommends horse meat for general use. Dried vegetables have great nutritive value, since they contain vegetable albumins. They should be made use of extensively in diet. Potatoes are valuable to replace bread. Green vegetables are much less valuable as nutrients, but they serve to alkalinize the organism and facilitate the emptying of the intestines; they are the police of the alimentary canal. Fruits are alkalinizing and laxative, but contain little nourishment. A piece of chocolate has more value than a pound of beefsteak. The author deprecates the use of alcoholics and advocates hot sweetened infusions of coffee, tea, chamomile, etc.—*Journal de Médecine de Paris.*

Book Reviews.

Memoranda on Poisons. By Thomas Hawkes Tanner, M.D., F.L.S. Eleventh revised edition by Henry Leffmann, A.M., M.D. Price, 75 cents net. Philadelphia: P. Blakiston's Son & Company, 1911.

The fact that this little volume has passed through eleven editions is a sufficient guarantee of its usefulness. Its teachings for the most part are sound, but some of the sections have not been brought up to date. Curare is stated to be "the only remedy which offers a chance of recovery" from rabies. Delirium tremens is not mentioned in the description of poisoning by alcohol. But the most surprising error of all is the classification of digitalis among the drugs "producing marked depression of the heart's action."

Die Klinik der Tuberkulose. Handbuch der gesamten Tuberkulose fur Aerzte und Studierende. Von Dr. B. Bandelier und Dr. O. Roepke. Price, 9.50 marks; bound, 10.70 marks. Wurzburg, Curt Kabitzsch (A. Stuber's Verlag), 1911.

This volume of nearly 500 pages is, to the best knowledge of the reviewer, the only complete handbook covering the etiology, prophylaxis, and treatment of all organs which may be attacked by the tubercle bacillus. The diagnosis with the careful description of symptoms and pathological lesions of tuberculosis of the lungs, the pleura, the upper respiratory tract, the digestive tract, the genito-urinary organs of both sexes, tuberculosis of the glands, liver, spleen, skin, bones, joints, the nervous system, and the eye and the ear are given in a clear and concise way.

A chapter on miliary tuberculosis, scrofulosis and tuberculosis in childhood completes this unique work. While the book is mainly intended for the practicing physician and the senior students of medicine, to the specialist it will be of value for reference and guidance in unusual and complicated cases. The book deserves to be translated into English and other languages, as has already been done with its companion, "Lehrbuch der Spezifischen Diagnostik und Therapie der Tuberkulose fur Aerzte und Studierende," by the same authors.

Lehrbuch der Spezifischen Diagnostik und Therapie der Tuberkulose fur Aerzte und Studierende. Von Dr. Bandelier und Dr. Roepke. Price, 6.60 marks; bound, 7.80 marks. Wurzburg. Curt Kabitzsch (A. Stuber's Verlag), 1911. 292 pages.

This is the fifth edition of this remarkable book since 1907. The present edition differs from its predecessors in that it is more complete and gives a few remarkably good illustrations of local tuberculin reactions and a large number of temperature charts. The book contains all that is known up to date of tuberculin as a diagnostic and therapeutic agent. With a few of the conclusions and statements of the authors some of our American tuberculotherapeutists may not quite agree. Thus, for example, while the authors admit the necessity of avoiding a rise of temperature, as far as it is possible, in their administration of tuberculin, they do not consider a temperature rise an indication to either refrain from a continued tuberculin administration, or at least to limit themselves to the smallest doses; the authors claim that an increase of doses is essential even under such conditions in order to obtain active immunization. Such disputed points must, however, be left to the attending physician's judgment and it only emphasizes the value of individualization which the authors also admit.

The rapid succession of new editions, and the fact that the book has already been translated into English, French, Japanese, Portuguese, Russian, and Spanish is perhaps as good a recommendation as can be desired. The present edition is dedicated to the great master Robert Koch and in it is reprinted the preface which Koch wrote for the third edition. The book cannot be too highly recommended to all those interested in this specific treatment of tuberculosis. To those who feel not quite at home in the German language, Dr. E. C. Morland's excellent English translation of the volume, published by Wm. Wood & Company, will be of great service.

Reflexions sur la Tuberculose. Par le Dr. E. Pettidi. Price, 3 francs. Paris: A. Maloine, 1911.

This little volume is written by a general practitioner of large experience. It gives his views on diet, on the sanatorium, on the contagiousness or rather the communicability, and on the therapeutics of pulmonary tuberculosis. The author's opinion on the fallacy of overfeeding (suralimentation) are sound and good; on the other hand, it would seem he goes to the other extreme when he speaks of a minimum alimentation with absolute rest in bed, always in the recumbent position and no manual or intellectual occupation whatsoever for weeks and months. Such treatment may be feasible and advisable in rare cases, but the practice of advising patients to remain constantly in the recumbent position has long been abandoned because of the danger of hypostasis of the lungs. Judicious, carefully supervised exercise has given better results than the exclusive and prolonged rest cure in bed or on the reclining chair.

It is refreshing to read what this French general practitioner has to say on the value of pure water in preference to the customary red and white wine drunk almost by everyone in France. Amusingly he speaks of the horror which French families have of pure water as a daily drink. He opposes strong liquors, cognacs, and whiskeys, but allows his patients moderate quantities of beer. The author does not speak too enthusiastically of the sanatorium treatment, but at the same time deeply deplores the treatment of the consumptive poor in general wards still in vogue in some of the great French hospitals, and he favors special institutions for this class of patients. He believes in the systematic treatment and is opposed to all medication or therapeutic measures which cause the patient any suffering whatsoever. The book, which is written in a pleasing style, carries conviction, and its perusal will be a pleasure and benefit to the specialist as well as to the general practitioner.

Urgent Surgery. By Felix Lejars, Professor Agrégé à la Faculté de Médecine de Paris; Chirurgien de l'Hôpital Saint-Antoine; Membre de la Société de Chirurgie. Translated from the sixth French edition by William S. Dickie, F.R.C.S. Surgeon North Riding Infirmary, Middlesbrough; Consulting Surgeon Middlesbrough Union Infirmary; Consulting Surgeon Eston Hospital. With 20 full-page plates and 994 illustrations, of which 602 are drawn by Dr. E. Daleine and A. Leuba, and 217 are from original photographs. Vol. II. The Genitrourinary organs. The rectum and anus. The strangulated hernias. The extremities. Price, $7.00. New York: William Wood & Company, 1910.

The contents of the second volume of this work includes the consideration of the genitourinary organ, the rectum, strangulated hernia, and the extremities. As in the first volume, the clinical features and operative treatment form the principle elements in the discussion, illustrative cases being interposed at frequent intervals to further elucidate the same. The references are almost entirely limited to the French writers, a matter of congratulation in view of the almost uniform exclusion of these from the usual English and German textbooks. The illustrations are numerous and very satisfactory and the general make up of the book is deserving of praise. Interest attaches to certain surgical procedures advised by the author, among them the treatment of cellulitis by incision with the thermocautery point. The discussion of strangulated hernia is very thorough and the author emphasises the value of early operation in preference to taxis unless in the most exceptional cases. He believes that the general practitioner should be prepared to practice the operation itself. The colloquial form of writing which is largely followed may not appeal to us and the urgency of some of the operations is likewise questionable, but this need not be regarded as a vital criticism and does not detract from the value of the work.

Insanity in Every-Day Practice. By E. G. Younger, M.D. (Brux.), M.R.C.P. (Lond.), D.P.H., etc., Senior Physician Frisbury Dispensary; late Senior Assistant Medical Officer London County Asylum, Hanwell; Formerly Assistant Medical Superintendent Metropolitan District Asylum, Caterham; Fellow of the Medical Society of London; Member of the Medico-Psychological Association of Great Britain. Second edition, revised and enlarged. Price, $1.25. Chicago: Chicago Medical Book Company, 1910.

Within this small volume of 124 pages there are presented the broad outlines of insanity with which the general practitioner ought to be familiar. The subject is treated from a practical standpoint, the author placing himself, as far as possible, in the position of the medical man, who, with little previous knowledge of insanity, may have to deal with a case of mental aberration at a moment's notice. The mode of examining a patient with a view to certification, and the various legal bearings of insanity, are presented in detail. Among the forms of insanity described are puerperal, epileptic and syphilitic insanity, syphilophobia, borderland states, feigned insanity, and "police court" insanity.

Society Reports.

AMERICAN GASTROENTEROLOGICAL ASSOCIATION.

Annual Meeting held at Philadelphia, Pa., April 19 and 20, 1911.

DR. WALTER B. CANNON OF BOSTON, PRESIDENT, IN THE CHAIR.

The Importance of Tonus in the Mechanical Activities of the Alimentary Canal.—Dr. WALTER B. CANNON of Boston, in his presidential address, said that the view that tonicity of the neuromusculature of the alimentary canal was a fundamental necessity in the appearance of rhythmic movements gave an explanation of many features regarding digestion and harmonized many diverse observations. It gave a reasonable explanation of the existence and importance of extrinsic motor nerves, it indicated the function of inhibitory nerves in the reduction or abolition of the tone, it accounted for the failure of efficient motility in atonic states of the stomach and intestines, it was in agreement with the observation that tonic contraction and rhythmical peristalsis reappeared later in cases of general body weakness, and it fitted admirably with the fact that the stomach of hungry animals was strongly contracted, the tonic state making the organ ready for instant action on swallowing food. Indeed, he was willing to believe that the sensation of hunger resulted from tonic contraction of the empty stomach.

Stretching of the Pylorus in Benign Stenosis.—Dr. MAX EINHORN of New York City read this paper, which was divided into two parts. In the first he described the stretching of the pylorus in children by means of an instrument called the infantile pyloric dilating catheter. This was a flexible tube with an inflatable rubber balloon at its end. In order to introduce it beyond the pylorus, the infant must first swallow either a small duodenal bucket or a metal olive attached to a silk string. After having ascertained that this has wandered beyond the pylorus, the dilating catheter is pushed along the silk thread into the duodenum, the balloon inflated, and the instrument withdrawn. Dr. Einhorn described the cases of two infants with congenital stenosis of the pylorus in whom he had applied this treatment. One patient had entirely recovered; the other had not been benefited. In the second part of the paper the author considered the subject of stretching of the pylorus in the adult, and described a new instrument, called the pyloric dilator and diaphane, consisting of a pyloric dilator with a tantalum (cold) lamp at its end. The advantage of this instrument consisted in the fact that it was possible by means of it to ascertain whether the end is in the stomach or the duodenum by means of internal illumination. The author then proceeded to describe three cases of real benign stenosis of the pylorus that had been very much benefited by the treatment. In order to insure success there must be no active ulceration in or near the pylorus, nor must the stricture be too far advanced.

Dr. MORRIS GROSS of New York did not consider it possible to get such a tube through a stenotic pylorus. He thought that if Dr. Einhorn had succeeded in getting his dilator to pass either stenosis did not exist at all or it was present to such a slight degree that stretching was not called for.

Dr. S. J. MELTZER of New York said that it did not sound very plausible to him that a single passage of the instrument could have been sufficient to reestablish function. Nobody had succeeded in stretching the cardia in so short a time, yet pylorospasm was much harder to reach than cardiospasm.

Dr. A. L. BENEDICT of Buffalo admitted frankly that he could not, as a rule, get a tube down through the pylorus, and said that bile on the end of the thread was no proof that the tube had entered the duodenum. He thought that a little medication would usually overcome the condition in a case of spasm.

Dr. CHARLES D. AARON of Detroit stated that he had pulled the tube through the pylorus, whether he had dilated it or not, fourteen times in a patient, with the result that she had gained eight pounds and was still increasing.

Dr. JESSE S. MYER of St. Louis said that Dr. Einhorn's experience proved that the condition called pylorospasm did exist and that it was evident that his method was curative in a certain number of cases.

Dr. WILLIAM GERRY MORGAN of Washington, D. C., cited a case in which the patient had had no symptoms on the first night after passing the dilator, probably owing to the psychic effect produced by that procedure, the pylorospasm recurring the next night. At operation it was found that no stretching would probably have been effective, owing to the nature of the cicatrix.

Dr. J. C. JOHNSON of Atlanta remarked that stenosis does not mean absolute closure. He thought that the fact that the size of the lumen can be increased by the withdrawal of instruments passed through the pylorus promised much in the treatment of these conditions.

Dr. MELTZER remarked that any foreign body in the duodenum near the pylorus would normally increase the pyloric contraction.

Dr. EINHORN agreed with Dr. Meltzer regarding this, but said that if the resistance at first encountered was gradually lessened with the same sized bulb one could conclude that there had been a real stricture. He considered his method applicable only to beginning strictures.

The Operative Treatment of Impermeable Cardiospasm.—Dr. WILLY MEYER of New York said that the cure of impermeable cardiospasm by means of dilatation was difficult or impossible. Therefore, operative measures would often be required. Von Mikulicz and Wendel had attacked the cardia from the abdomen, but the trouble could also be successfully and permanently cured by way of the thorax. In support of this view Dr. Myer mentioned a case in which a cure was obtained by means of thoracotomy, tearing the nerve filaments that enter the esophagus on each side from the pneumogastrics and reducing the large esophageal pouch above the diaphragm with the help of a double plication.

Cardiospasm in Infants, with Report of Cases.—Dr. WILLIAM GERRY MORGAN of Washington, D. C., said that reports of cases of idiopathic dilatation of the esophagus occurring in young children had appeared in medical literature from time to time, but that in a very few instances had stenosis of the cardia not due to injury been noted. Cardiospasm with dilatation of the esophagus occurring in infants under one year of age had not, thus far, been reported, and it was such cases with which his paper had to deal. He had had such a case, which was treated by Dr. Einhorn's method, and had also had a case of cardiospasm in an adult, which had been treated by gradual dilatation with bougies, the patient failing all the time. He stretched the cardia with Dr. Einhorn's forcible cardia dilator. This patient is now eating everything and has gained nineteen pounds in weight.

Remarks on Cardiospasm.—Dr. S. J. MELTZER of New York referred to a case of cardiospasm published by him twenty years ago under the term "dysphagia," in which he had given the entire clinical course of cardiospasm and predicted what would be found at autopsy. The patient did not die for five years after this and circumstances prevented him from publishing the autopsy findings. He then stated that the absence of the deglutition sound in the stomach when it is present down as far as the tenth or eleventh vertebra means an elastic stenosis.

Dr. J. C. Hemmeter of Baltimore gave an account of a very severe case of cardiospasm in which the esophagoscope went in, but in which, when the patient swallowed, there came a spasm that prevented anything from going through. He thought that a distinction should be made between this condition and those cases in which the spasm is always present. He had had only temporary success in dilating the cardia by mechanical methods.

Dr. J. Kaufmann of New York stated that among his patients a surprisingly large number had dated their first attack of cardiospasm to a hot day on which they had taken ice-cold soda water. Probably the first spastic contractions led to the development of erosions, which kept up the irritation. He considered hyperacidity as another cause of erosions.

Dr. L. Kast of New York thought that the term cardiospasm should be dropped in favor of one suggesting the relation of the cardia with the parts of the digestive tract above and below it. He mentioned a case of reversed peristalsis of the stomach, forcing the food through the esophagus to the mouth.

Dr. Jesse S. Myer did not see why Dr. Willy Meyer had not in his case tried gastrostomy with forcible stretching of the cardiospasm and did not consider the size of the pouch a contraindication to this procedure.

Dr. Johnson mentioned a case of almost complete esophageal obstruction in which operation could not be considered, and described how he had managed to get a dilating instrument to pass by means of the galvanic current. The patient will probably get entirely well.

Dr. Robert T. Morris of New York stated that in cases of cardiospasm careful examinations should first be made to eliminate the possibility of irritation of the vagus at the base of the brain through eye-strain, floating kidney, adhesions in the bile tract region, a neurotic temperament, and the stigmata of decadence.

Dr. Einhorn referred to absence of the swallowing sound as an aid in the diagnosis of partial cardiospasm with dilatation of the esophagus, and said that patients treated by his method get entirely well. He did not consider that there should be any difficulty in making the differential diagnosis between this and malignancy.

Dr. Willy Meyer stated that his patient had been too weak for an abdominal operation and it seemed better to adopt the thoracic route. He did not feel sure whether the double plication had really been necessary or not.

Some General Remarks on the Treatment of Gastric Disturbances.—Dr. J. Kaufmann of New York said that correct treatment required correct diagnosis and referred to the progress made in the reading of gastric analyses, especially regarding the relationship of motor and secretory disorders, assisted in directing treatment along the right lines. Aside from properly interpreting disorders of gastric function, one should consider their pathological meaning. There must be a differentiation of primary and secondary gastric disturbances. Among the latter, those caused by chronic appendicitis, cholelithiasis, etc., are much emphasized at present. While undoubtedly occurring, Dr. Kaufmann thought that their frequency was greatly overrated and that too much importance was given to this special etiological factor at the cost of others known as provokers of gastric disturbances. Every etiological factor should be taken into account. At the same time, the condition of the stomach proper required consideration.

Dr. John A. Lichty of Pittsburg said that in spite of medical treatment carried on for a long time in cases of hyperchlorhydria patients would often continue to oversecrete, although they might improve in general health. Quite a number of such cases, he thought, could be improved by surgical intervention. This continuance of oversecretion after the removal of the original irritant was attributed to cell-habit.

The Gastric Weak Line in Wounds of the Abdominal Wall.—Dr. Robert T. Morris of New York said that failure of union of the abdominal wall wound after many of the stomach operations seemed to call for special explanation. The failure of union apparently meant a trophic disturbance, and this incidentally corresponded to the area of superficial sensory disturbance described by Head for the gastric zone. It was probable that irritation of the nerves of the stomach, referred to their respective segments of the spinal cord, was continued as an impulse to the superficial gastric area, which was commonly irritated coincidently with irritative processes of the stomach. This feature had been recorded with reference to hyperesthesia of skin zones, but the question of trophic nerve disturbance leading to failure of operative processes in the superficial gastric zone seemed to have escaped attention previously.

Dr. J. C. Hemmeter said that before accepting the hypothesis of Dr. Morris it would be necessary to prove that the stimulus went from the gastric zone to a segment of the cord from which the trophic nerve came out.

Dr. Kast considered the idea a very happy one, and said that it would again attract attention to the viscerocutaneous reflex and to the mutual reflex association between the internal organs and certain areas of the skin.

Dr. Meltzer was surprised that the idea should not have suggested itself to Dr. Morris that the stimulus might not be a nervous, but a chemical one. He thought it possible that it might be due to bile and pancreatic secretion that the stitches gave way.

Dr. A. G. Gerster of New York said that this occurred after operations in every region of the body, and thought Dr. Meltzer's explanation quite plausible. Anesthesia alone was often sufficient to disturb the pancreatic and gastric secretions so much as profoundly to change the chemical processes of the body for a long time after the operation.

Dr. Morris stated that the fact that repair did not take place in a case in which there was irritation of the pylorus had led him to the conclusion that there was a trophic disturbance in that particular group of nerves coming from a certain definite segment of the cord.

A Case of Banti's Disease.—Dr. J. Fuhs of Brooklyn said that the case of Banti's disease that he wished to present was successfully treated by splenectomy, the patient afterward passing through an attack of typhoid fever and an operation for appendicitis. Dr. Fuhs emphasized the remarkable results that followed splenectomy in this case, the lasting improvement, and the ability to combat infection, and also the restoration of the blood to its normal condition as to the formed elements, and to a marked increase in its coagulability. She had a typical, characteristic attack of typhoid fever, differing in no way from such attacks in patients not operated upon, with the exception of the blood findings, which showed a rather high leukocyte count for a case of typhoid, and a relatively high polymorphonuclear leukocytosis. The reaction to the surgical interference during the course of the typhoid did not present anything characteristic, and her recovery was as rapid as could be expected in a patient not splenectomized.

Dr. Hemmeter exhibited a patient with Banti's disease showing some very peculiar landmarks. This patient had profuse hemorrhage from the bowels, ascites, a very large spleen, and cirrhosis of the liver, and had been operated on for appendicitis and had had typhoid fever. The blood-picture was typical of Banti's disease. The fact that typical splenic cells have been found by Mallory in the portal veins Dr. Hemmeter considered striking evidence that the spleen is really the starting point of the troble and not the liver.

Dr. Kaufmann referred to a case of his in which some clinical facts pointed to the origin of the disease in the spleen and said that this organ should be removed when

one can be sure that it is the primary seat of the trouble. He did not consider the blood-picture typical, it having been that of pernicious anemia in his case.

Dr. J. C. Bloodgood of Baltimore said that in three cases of Banti's disease in which splenectomy was not done the results had been just as good as in three in which it was done. The treatment was rest with arsenic and iron.

Dr. L. Kast believed Banti's disease to be only a symptom-complex and stated that the fact that it might be a syphilitic or a post-syphilitic condition should be borne in mind.

Dr. Fuhs stated that clinically it was impossible to differentiate between cases of Banti's disease and cases in which tuberculosis or granulomata of the spleen were found. He thought that the hemorrhage and the blood-findings spoke in favor of its being a toxemia. The Wassermann reaction had been positive in two recently published cases.

The Relation of Symptoms to Pathological Findings in Cancer and Ulcer of the Stomach.—Dr. J. C. Bloodgood of Baltimore spoke of a case of ptosis of the stomach and colon, the first case that he had resected for ptosis. He resected a little beyond the pylorus to a point that would make a straight line of the greater curvature and of the duodenum, suturing the duodenum to the stomach according to the method of Kocher, and then turning in the end. Dr. Bloodgood considered resection of the stomach for ptosis the simplest resection, because there are no adhesions. Things are so relaxed that there is very little shock. This patient had no postoperative complications after thirty-six hours. He had been relieved of the stasis of material in his stomach and colon, causing constipation, and the diarrhea is also over. The operation has been done ten weeks and the man has gone back to his work. The other case was one in which he suspected cancer of the pancreas. On exploring the abdomen he found a small nodule on the head of the pancreas. There was a large gall-bladder, and in the common duct he could feel this nodule. It was not a stone. Dr. Bloodgood considered it impossible to imagine a cancer of the diverticulum of Vater that would not infiltrate the duodenum. Local resections of the tumor itself have been done without any success, owing to the fact that the cancer has been cut through. In this case, in which there were clay-colored stools before operation, bile appeared with the first stool, and the patient is gaining in weight, showing that the loss of the pancreatic secretion is not incompatible with a gain in weight.

Some Leading Points in X-Ray Examination of the Digestive Tract; Lantern-Slide Demonstration.—Dr. P. M. Hickey of Detroit accentuated the following points: (1) That it is exceedingly unwise to form opinions from the Röntgen examination without due consideration of all the factors in the case; (2) that, though a fluoroscopic examination of the gastrointestinal tract offers certain advantages, yet the inherent danger at the present time does not warrant its wide application; (3) that a stereoscopic method of examination offers certain advantages in selected cases; (4) that by the use of plates made at succeeding intervals after the bsmuth meal the diagnosis and degree of pyloric insufficiency can be determined; (5) that the position of the stomach as found at operation or autopsy does not correspond with the position of the stomach when the patient is in the erect position and when it is filled with food; (6) that the mobility or immobility due to adhesion of the colon can be determined by a careful comparison of the plates made in the erect, horizontal, and Trendelenburg positions.

Further Experiences with the X-Ray Diagnosis of Ulcer of the Stomach and Duodenum, Embracing Fifty Cases; Lantern-Slide Demonstration.—Drs. Henry Adler and Howard E. Ashbury of Baltimore presented this paper. From a study of these cases, they held, the following conclusions seemed to be justified: (1) The retention of bismuth given according to their method for a period of over four hours signified a pathological condition other than mere displacement; (2) the absence of a bismuth shadow from the stomach area examined in small, isolated spots was not due to stenosis or simple dilatation, but to ulcers; (3) while they believed that a distinct effect had been made in ulcer diagnosis, that a valuable sign had been developed which, when present, would justify them in carrying out their treatment with assurance in otherwise doubtful cases, yet they felt that the *x*-ray examination should not at present be looked upon as giving by itself a final verdict, but rather should bear weighty evidence when taken in combination with the other clinical data. The *x*-ray examination having shown a definite ulcer-shadow before treatment was instituted, its persistence or absence in later radiograms after the treatment should be an index of the result of such treatment. Some work has been done on this line, but the writers' experience was too young to report data of value.

Neuromuscular and Secretory Coordination Between the Stomach and the Duodenum.—Dr. J. C. Hemmeter of Baltimore brought out the following points: (1) Secretion in the duodenum was not augmented by the presence of hydrochloric acid in the stomach side of the sphincter pylori. The hydrochloric acid or its derivatives must enter the duodenum. There was a periodic undulatory secretion of the intestinal juices in the fasting condition. (2) Psychic secretion of pancreatic juice occurred in man. (3) Jejune or fasting peristalsis occurred in the human being, probably as a means of evacuating products of excretion. This could not be observed by the bismuth and *x*-ray method, because the digestive tract was not empty when bismuth was given. Observations on duodenal and ileocecal fistulas showed it, however. (4) There was a relation between the presence of bile and pancreatic juice in the fasting stomach to (*a*) disturbance of reciprocal intervention between the sphincter of Vater and the gall-bladder in enteroptosis and (*b*) the normal jejune or fasting peristalsis of Pavlov and Boldyreff.

A Contribution to the Knowledge of the Function of the Duodenum.—Dr. L. Kast of New York said the bulbus duodeni frequently showed food retention, which could be seen on the fluoroscope, if bismuth was mixed with the food. The food retention was ofte nassociated with altered peristalsis of the pyloric portion of the stomach and was the explanation for a variety of subjective gastric symptoms. The duodenal food retention had a diagnostic significance.

Duodenal Ulcer.—Dr. Lewis Brinton's paper was read by Dr. Walker in the author's absence. It stated that the principal symptom of duodenal ulcer was pain. There were several remarkable features about the pain of duodenal ulcer that served to differentiate it from any other kind of pain. Hemorrhage, while quite frequent in small quantity, was seldom so severe or so productive of alarming symptoms as in gastric ulcer. Vomiting occurred in one-fourth of the cases and showed nothing of uncommon interest. Tenderness over the stomach was usually pretty constant in its position. Occasionally there were signs of gastroptosia associated with the ulcer. Gastric analysis offered but little aid in the diagnosis. Dr. Brinton considered pancreatic action as a factor in the sum total of our diagnostic evidence in duodenal ulcer. No claim was put forth that this test is pathognomonic, but he believed that it did afford a link in our chain of diagnosis. The diagnosis having been established, the examination of the feces at frequent intervals for occult blood constitutes a valuable index to control the modification of the diet and surgical treatment.

The Cause and Relief of Pain in Duodenal Ulcer.—Dr. James Taft Pilcher, Brooklyn, after a study of one

hundred cases in which this diagnosis had been made and confirmed by operation, together with some experiments on a series of dogs, reached the following conclusions: (1) Ulcer of the duodenum reflexly excited a hyperacidity of the gastric juice. (2) The maximum amount of secretion of hydrochloric acid in the stomach was due to a direct chemical action (hormones) and was at its height from one to four hours after meals. (3) It passed into the duodenum as hydrochloric acid, there being no food four hours after meals for it to work upon. (4) It did not excite a flow of the duodenal juice directly, and was not neutralized by the small amount present. The relief of pain in duodenal ulcer followed the ingestion of any substance into the stomach which neutralized the acid gastric juice. This conclusion was based on the following facts, already demonstrated in the above experiments: (1) Food taken into the stomach excited at once a reflex secretion in the duodenum; (2) the duodenal secretion was alkaline in approximately the same degree as the gastric juice was acid; and (3) this secretion was of sufficient quantity and concentration to neutralize the hydrochloric acid of the gastric juice.

Perforation in Duodenal Ulcer, with Report of Cases.—Dr. Lichty considered the diagnosis of duodenal ulcer as essential for the prompt diagnosis of perforation. He reviewed some of the leading points necessary to make a diagnosis of chronic ulcer, and referred to the distinction between acute perforation and so-called subacute and chronic perforation. From observations in the operating-room, as well as in the autopsy-room, he thought that it could be readily seen how an acute perforation not operated upon might not necessarily be immediately fatal. For this reason, perforating duodenal ulcer was frequently unrecognized. He reported a case illustrating this point, and also one of acute perforating duodenal ulcer that before operation had presented the symptoms of cholecystitis.

Hyperchlorhydria and Pyloric Obstruction Due to Cancer Developing in Duodenal Ulcer.—Dr. A. L. Benedict of Buffalo stated that the lesion had probably existed quite a while before the beginning of the period covered by the history, six weeks. There were no marked gastric symptoms. It was not until sudden collapse took place that the real state of the patient's nutrition was realized. The ischochymia was appreciated. The absence of liquid bowel movements was attributed to organic pyloric obstruction of some kind, even before the momentary feeling of a tumor; but it was obvious that the obstruction was not absolute. Owing to the distortion of landmarks, the questions of gastric dilation and hepatic contraction were not answered by the physical examination. While the extracted stomach contents were abnormal they were well within the limits to which one was justified in speaking of gastric dilatation. Owing to the restriction placed on the post-mortem examiner, neither question was positively answered at necropsy. The question of cancer arose early, and this diagnosis was considered highly probable at the outset; but with the demonstration of a degree of free hydrochloric acid this diagnosis of carcinoma, unless in its incipiency, did not seem so probable, until the tumor was felt. In the author's experience, every case in which food had been retained in the stomach over twenty-four hours had proved to be malignant; but even considerable degrees of ischochymia did not warrant the diagnosis of malignancy. The location of the lesions in the duodenum, even the pyloric tumor being an invasion from the duodenum, explained the inconsistent findings. There was no history of bloody or dark passages. Apparently the ulcer had not bled recently; but no fecal matter was available, and the duodenum obviously could not have been infected through the stomach.

Dr. Robert T. Morris believed that Dr. Kast's work would give an opportunity to make a diagnosis in these cases of cobwebs in the attic of the abdomen, which occurred most commonly from the influence of toxins taken from the colon by the efferent vessels of the portal system and excreted by the liver. He considered that both hypersecretion and hyposecretion meant a derangment of the hormones through deranged hematin secretions acting on the area of the bowel secondarily from adhesions throwing off endothelium of blood-vessels, and causing proliferating endarteritis of terminal arteries.

Dr. Fuhs stated that, if the urine of a patient suspected of malignant disease be examined by adding methylene blue and allowing this mixture to stand in a test-tube from twelve to twenty-four hours, the blue would be found decolorized when malignant disease was present, but not if it was absent. Those few other diseases in which it is decolorized can readily be differentiated from malignancy.

A Study of Six Cases of So-called Larval Hyperacidity.—Dr. Julius Friedenwald of Baltimore said that cases were not uncommon in which symptoms of hyperchlorhydria existed, and yet the gastric contents showed a diminution or a complete absence of hydrochloric acid. This condition was explained on the basis of a gastric hyperesthesia. In addition, there were a certain number of cases manifesting similar symptoms, in which the gastric contents presented a normal or a lessened proportion of acid; and yet in which, during the earlier periods of digestion, a hyperchlorhydria was at hand. Roth and Strauss first drew attention to this condition; but it was more carefully investigated by Schuler, who termed it "hyperaciditas larvata." In the larval hyperacidity there was an actual hyperacidity, which was often not revealed, inasmuch as the gastric contents were not extracted early enough; for the secretion, which at an earlier period would present a hyperacidity, was gradually neutralized before the end of an hour when taking an Ewald test-breakfast. Observations over a series of six cases had been made. Test-meals were given, and removed at varying intervals; and while the percentage of free hydrochloric acid was normal and subnormal at the end of an hour after an Ewald test-breakfast, yet it was found that there was a period in which a hyperchlorhydria was manifested.

Gastric Hypersecretion.—Dr. Arthur F. Chace of New York stated that the results regarding the secretory function of the stomach obtained by the original Ewald-Boas test-breakfast were not so conclusive as they were originally assumed to be, mainly on account of the closely interrelated and overlapping effect of motility and secretion. In this respect, the dry test-breakfast, as proposed by Boas, eliminated certain features. The result obtained from more than two hundred tests threw light on the extent to which secretion is influenced by motility, and suggested that in cases of disordered motility the dry test-meal was a more accurate index of the secretory function of the stomach than is the wet. The rôle of fatigue in gastric function was important.

A New Test-Breakfast.—Dr. Dudley Roberts of Brooklyn considered the Sahli test meal and its modification by Friedman, for the estimation of the actual residue of test-meal and secreted gastric juice, to have inherent disadvantages dependent upon the use of a fat-emulsion. The writer suggested the use of lactos added to weak tea to the strength of ten per cent. After the lapse of one hour a portion of chyme was extracted, and water in known amount added; and a second extraction was performed. By the Mathieu-Raymond formula, the total residue was calculated; and by the estimation of the lactose present, the amount of test-meal remaining was accurately determined. The estimation of the lactose in such a solution was simple. It would seem that the

method, because of its simplicity and accuracy, might be worth general adoption.

A New Sigmoidoscope.—Dr. DUDLEY ROBERTS thought that sigmoidoscopy should be an important work of the gastroenterologist. The writer had made it a routine part of the examination in cases of disturbed function of the bowel and others in which it was indicated. In this instrument, the obturator was much more olive-shaped than in the other forms of sigmoidoscope and proctoscope. Dr. Roberts considered it a foolish idea that obturators must be made rounded because it was dangerous to shove anything with a sharp point into the bowel; for the instrument was not introduced any further than the anus. There was in this sigmoidoscope a side tube, carrying a small light, the light-holder being standard in all instruments. The rays were passed down, and, by reflection became parallel. At the proximal end of the instrument there was a window which was screwed on. The glass was the full size of the lumen of the tube. Therefore, there was no obstruction whatever to the view. There was another small tube for connection with the rubber dilating bulb. It was surprising what a bright light one could get with this instrument, and it apparently worked as well in a small-caliber tube as in one of larger caliber. The light was thrown two or three inches from the end of the tube, which was as far as the curve in the bowel would allow one to see. The instruments were made in four sizes.

Further Experience with the Benzidin Test for Occult Blood in Diseases of the Digestive Organs.—Dr. F. W. WHITE of Boston gave a review of the literature of the subject, and referred to the results with the Schlesinger and Holst modifications of the benzidin test in several hundred recent cases. He described the technique of the test, and said that he did not consider it over-delicate, a large majority of negative results having been obtained. In feces, positive results were obtained only with ulcerative lesions of the gastrointestinal tract and hepatic cirrhosis. The benzidin test has many advantages over the guaiac test. The author also made a brief comparison between the benzidin test and the phenolphthalein test for occult blood.

Dr. ALBERT BERNHEIM of Philadelphia stated that within the last few weeks he had tried a new test with fluorescin, which acted in the same way as phenolphthalein, and was more delicate than the latter in some cases.

Dr. ROBERTS had come to the conclusion that positive findings were of great value in the benzidin test, but that negative findings indicated comparatively little. Several times he had been much confused because patients had taken hemoglobin preparations, and he had had to guard against this source of error with great care.

Dr. FUHS stated that in testing for blood in the stomach contents he always tested the saliva also for blood. Benzidin added to stomach contents, he further stated, seemed to have the property of liquefying mucus.

Dr. BENEDICT had found several cases in which the occult blood in the feces came from a spot but ten inches above the anus.

Dr. WHITE thought that both the positive and the negative findings had a good deal of value. If in patients with suspicious symptoms he found no occult blood after they had had time to develop cancer, he considered this good evidence against the existence of malignant disease. He considered positive results in the feces of much more value than the same results in the stomach contents.

Lymphocytosis in Certain Gastrointestinal Cases.—Dr. JOHN P. SAWYER of Cleveland stated that in practically all his cases, for several years, a differential count has been made under his own control; and in the course of these observations he had often found the differential count of clinical advantage. He did not refer in this clinical study to established departures from normal counts, as found in the known so-called blood diseases. He wished to speak more especially of the considerable variations from the usually accepted average differential counts in adults; for in children the known mononuclear lymphocyte counts were in high proportion. The average lymphocyte count was about 30 per cent. A slight variation from this was not of considerable moment; but when the lymphocyte count rose to forty or fifty per cent., this was probably indicative of a considerable departure from the usual blood formation. The lymphocytes were the product of the lymph tissues, discharged into the blood. Therefore, from a study of cases of high lymphocytosis, it was possible to gather information regarding possible stimulation of lymphatic tissue. These large lymphocyte counts were found without leucocytosis in a considerable number of diseases; among them cases of gastrointestinal disease. It occurred in cases in which gastrointestinal catarrh was not discoverable by examination of the test-meal or of the stool; and in which the history showed no record of the existence of such catarrh recently. The condition of the gastric secretion seemed to have no determining influence upon this lymphocytosis. It was usually found in persons whose resistance was low. In such cases it was possible, by treatment of the patient, to bring about a very prompt and decisive change in this lymphocytosis. This treatment consisted in the administration of iodide of iron for a few weeks and the exhibition of arsenic. It brought about a prompt reduction in the lymphocyte count, and the patients gained rapidly in weight and strength.

Dr. MELTZER had come to the conclusion that there was a difference in the ferment between the leucocytes and the lymphocytes, one acting in alkaline, and the other in acid media; and he thought that there might be a definite relation between acidity and lymphocytosis.

Is Pellagra Primarily a Disease of the Digestive Tract?—Dr. J. C. JOHNSON considered pellagra as a disease distinct from all others. It was not acute in the sense that idiopathic fevers were. Its duration was strangely variable. Necessary to its development were certain positive conditions of the organism: chiefly a disturbance of inorganic balance. These conditions were emphasized with the progress of the disease. It often existed long before it was recognized or suspected. Gastrointestinal symptoms were usually the first to appear, and were in proportion to the gravity of the attack. There was an absence of hydrochloric acid in advanced cases; and in many a lack of ferments. The cases were treated successfully with chloride of potassium, tincture of iron, and essence of pepsin.

Dr. MELTZER thought that the fact that in the serious cases of pellagra there was no hydrochloric acid, and that the cases that in which there was hydrochloric acid had no serious symptoms, indicated that the cause of the disease was of a kind that had to pass the stomach. If hydrochloric acid was present in sufficient strength there the disease would not develop.

Demonstration of a Case of Voluntary and Intentional Regurgitation.—Dr. ALBERT BERNHEIM of Philadelphia said the patient, a young physician, could regurgitate food voluntarily and intentionally, whenever he desired to relieve symptoms of gastric distress. He usually took a glass of water, to liquefy the contents of his stomach, so that they might come up easy; and also some bicarbonate of sodium, so that the acidity of the regurgitated material might not injure the mucous membrane of the throat and mouth. He then bent over, so that the abdominal muscles compressed the stomach. The esophageal opening of the stomach then dilated, and the food came out.

Dr. Meltzer said that he could hear what he called the second deglutition sound, which occurred immediately after the beginning of swallowing, indicating that the cardia was patent. He considered this the reason why the patient could relieve himself so readily of the contents of the stomach.

Dr. A. Owaroff of Philadelphia (the patient) said that if the cardia were always open he would get some fluid in his mouth when he bent down; but that it was only when he wished it to do so that the fluid came up into his mouth.

Dr. Meltzer explained that a patent cardia did not mean one that was always entirely open. It had a moderate degree of closure, which was overcome by a very slight stimulus, such as that afforded either by the beginning of deglutition or by the pressure with the abdominal muscles. He was not inclined to believe the opening of the cardia voluntary.

Constipation with Diarrhea.—Dr. Albert Bernheim of Philadelphia said that some varieties of constipation were found in cases of gout after operation (adhesions, kinks, spasms and some in tuberculosis; and others manifested themselves, not as constipation in the usual conception of that condition, but apparently as cases of diarrhea. There were symptoms of autointoxication (vasomotor ataxia) and nervous conditions; also symptoms simulating appendicitis. Tests should be made for peristalsis and fecal matter. The treatment was medicinal, physical, hygienic, and dietetic.

Dr. Fuhs, in connection with the difficulty in differentiating between appendicitis and stagnation and impaction of fecal matter in the cecum, mentioned the fact that there was a point of marked tenderness at the second intercostal space in the latter condition, on a line drawn from the middle of the clavicle downward.

Mitral Murmurs in Gallstone Disease.—Dr. David Riesman of Philadelphia said that in a number of cases of gallstone disease he had heard a mitral systolic murmur during and shortly after an attack of colic. He had found these murmurs perplexing when the advisability of operative treatment was to be weighed. In all the cases seen by him the murmur had not existed prior to the attack of colic. It was not due to endocarditis, for it disappeared soon after the attack. It was not due to anemia, and it was not due to jaundice, because it could be heard in cases that did not have icterus. It probably depended on temporary dilatation of the heart. Dr. Riesman believed that the chronic disease of the biliary tract, with its accompanying infection, had caused a myocardial degeneration, somewhat akin to that found in connection with fibroid tumors of the uterus. The degeneration predisposed the heart to dilatation when, during the attack of colic, the blood-pressure rose. The murmur was loud and unmistakable. The heart was enlarged, but not to any great degree. Dr. Riesman did not consider the presence of the murmur any contraindication to surgical intervention. Indeed, if the pathogenesis was as stated, it would constitute a point in favor of operation. Care should, however, be taken in giving the anesthetic.

Dr. Meltzer drew attention to the fact that sometimes a murmur would exist in association with pain so excruciating as to lead one to believe it due to some trouble with the gall-bladder, while it was really a symptom of angina pectoris. He had no doubt, however, that in Dr. Riesman's cases there were definite evidences of the existence of gallstones.

Dr. Fuhs had seen two cases of distinct biliary colic with asthmatic attacks in patients who had never had any asthmatic attacks before the attack of cholelithiasis, and never had one after it. There was no functional or organic disturbance of the circulatory system either before or after the attack of gallstones.

Dr. Riesman agreed with Dr. Meltzer that angina pectoris might manifest itself wth pain in the epigastrium or upper abdomen, but stated that he had been speaking of genuine cases of gallstone disease.

Officers.—Dr. Walter B. Cannon was reelected *President*, and Dr. F. W. White of Boston was elected *Secretary-Treasurer*.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting held May 4, 1911.

The President, Dr. William M. Polk, in the Chair.

This meeting was held under the auspices of the Section on Genitourinary Diseases.

To Abolish the Section on Public Health.—It was moved, seconded, and carried that this section of the New York Academy of Medicine be abolished. It was suggested that this might come up again for consideration at the next meeting of the Academy.

The Use of Common Drinking Cups.—Bill No. 505, introduced into the Senate by Mr. Sanner, states as follows: "The People of the State of New York, represented in Senate and Assembly, do enact as follows: Section 1. Article sixteen of chapter forty-nine of the laws of 1909, entitled 'An act in relation to the public health, constituting chapter forty-five of the consolidated laws,' is hereby amended by inserting at the end thereof a new section, to be section three hundred and thirty-five, to read as follows: 'The establishment of a public drinking cup in any public place, vehicle, or building is prohibited, except in accordance with rules and regulations adopted by the State Commissioner of Health, which he is hereby authorized to adopt for the purpose of preventing the spread of communicable diseases by the use of such cup. Any person who violates this section or any rule or regulation of the State Commissioner of Health made in pursuance thereof shall be guilty of a misdemeanor punishable by a fine of not more than twenty-five dollars. This act shall take effect September 1, 1911.'"

Dr. Alfred Meyer moved that the Academy of Medicine endorse this bill which was now before the Legislature. Dr. A. Jacobi seconded this motion, which was unanimously carried.

Resolution Regarding the Practice of Midwifery.—The Section of Obstetrics and Gynecology presented the following resolution, which was adopted: *Whereas*, It is estimated that about 50 per cent. of the births in the large cities of this country are attended by midwives (in New York City, approximately 50,000 births are reported annually by midwives), and *Whereas*, The profession of midwifery in this country is followed, in most instances, by ignorant, untrained, incompetent women, and *Whereas*, Some of the results of obstetrical malpractice are unnecessary blindness, mental and physical degeneracy, and death of infants, and unnecessary suffering, invalidism and death of others, and *Whereas*, Although both doctors and nurses in this country are given instruction in the treatment and care of child-bearing women and new-born infants, there is no existing provision for the adequate training of women who take into their keeping the lives and future well being of this large number of both mothers and infants, be it *Resolved*, That the New York Academy of Medicine recommends that measures be taken in the State to secure State legislation which shall provide for the training, registration, licensure, supervision, regulation, and control of women engaged in the practice of midwifery.

Resolution Regarding the Open Air Stairway.—The Section on Pediatrics presented the following resolution, which was adopted: *Whereas*, In the Tenement House Law there is no recognition of the new open air stairway, and *Whereas*, The air shaft becomes superfluous in open stairway construction of tenements as illustrated by the

buildings in Seventy-seventh street and the East River, and *Whereas,* The air shaft, besides being superfluous for the purpose of ventilation, takes from the living quarters needed room space, and is, furthermore, a possible means of close communication between adjacent apartments, transmitting noise, possibly dust, germs, and fire; be it *Resolved,* That it is the sense of this meeting that in buildings having open stairs of this type the shaft should not be required, and that bathrooms be allowed to ventilate upon the open stairs, and be it *Resolved,* That it is better to locate and ventilate the bathrooms on the open stairs rather than to locate them on the outside walls of the building, as this space is better utilized for bedrooms, living rooms, and kitchens; and be it *Resolved,* That a copy of this resolution, after endorsement by the Academy of Medicine, be forwarded to the departments having jurisdiction.

The evening was devoted to the discussion of recent developments in kidney surgery.

The Phenolsulphonephthalein Test in Relation to Prostatectomy and Nephrectomy.—Drs. E. L. Keyes and A. R. Stevens presented this communication. About a year ago Drs. Rowntree and Geraghty reported the results obtained with the phenolsulphonephthalein test upon one hundred and thirty patients, and set forth the advantages of this test over those previously used. A few weeks after this report Dr. Stevens began a series of observations upon the efficiency of phenolsulphonephthalein as a renal functional test, and in October Dr. Keyes joined him. They had applied the test to ninety-four cases. Phenolsulphonephthalein was injected subcutaneously, the amount administered being six milligrams in one cubic centimeter. It was excreted almost exclusively by the kidneys, and was readily identified in the urine by its brilliant scarlet color in alkaline solution (the alkalinity being obtained by the addition of a few drops of sodium hydroxide in solution). Rowntree and Geraghty found as a result of twenty-seven tests upon twenty-one patients with apparently normal kidneys that the drug appeared in from five to twelve minutes, that, as measured by the Duboscq colorimeter, from 41.6 per cent. to 66 per cent. was excreted within the first hour thereafter, from 11.9 per cent. to 26.5 per cent. in the second hour: a total for the two hours of from 61 to 85.8 per cent. In Dr. Keyes' and Dr. Stevens' observations upon eight normal cases they obtained similar but lower figures. The onset of secretion varied from 5 to 13 minutes. Excretion in the first hour was 38.2 to 57.9 per cent.; during the second hour, 5 to 13.3 per cent.; the total for two hours was 49.4 to 71.2 per cent. After the second hour the percentages were always very small, though, of course, when renal disease restricted the early output the later output was relatively higher. Their observations confirmed the opinion that 40 per cent. for the first hour and 50 per cent. for the first two hours was a sufficient output for two normal kidneys. Their experience confirmed what Rowntree and Geraghty had noted, that the output of color was quite independent of the renal output of water. They found no advantage in having the patient drink 300 or 400 c.c. of water, except when the ureters were to be catheterized. They had found a very grave source of error in studying the total kidney function from specimens obtained by ureter catheterization, and this was retention of the drug as a result of functional disturbance incident to ureteral catheterization. This error was readily disclosed by control observations taken the day before or the day after the cystoscopy. Among fourteen cases upon whom this comparative test was made only six failed to show a marked deficiency, due to ureteral catheterization. In exceptional cases even the passage of a catheter in order to determine the exact time of the appearance of the color may cause sufficient inhibition to vitiate the test. They purposed in the future to omit all notice of the delay in appearance of the drug in estimating percentages and to count the hours from the time of injection instead of from the time when the drug appeared in the urine. In regard to the results obtained by the phenolsulphonephthalein test in cases of prostatic hypertrophy they found that: (1) The phenolsulphonephthalein test did indeed indicate renal deficiency in prostatics more accurately than any other urinary test. (2) Operation was contraindicated when only traces of the drug appeared in two hours after injection. They disagreed with the following points: (1) They did not recognize a diminished phenolsulphonephthalein output as an absolute contraindication to operation. (2) They did not pretend to know how low the phenolsulphonephthalein output might be, and yet the patient survive prostatectomy. (3) They felt that, apart from hexamethylenamine and water before operation (both of which might be overdone), the patient's greatest safeguard in desperate cases lay in preliminary drainage by suprapubic or perineal section, followed after a suitable interval by prostatectomy under spinal anesthesia. In their study of cases of renal infection, of which they had thirty-three cases, five of whom had been nephrectomized for tuberculosis and five others upon whom for various reasons the phenolsulphonephthalein test was not employed in conjunction with the ureter catheter, leaving twenty-three upon whom the combined test was applied, ten cases came to nephrectomy after the test was applied, and upon these they based their conclusions, which agreed quite closely with those of Rowntree and Geraghty. However, they ventured the following criticisms: (1) While they found the phenolsulphonephthalein test far superior to the other artificial color tests in that it showed marked superiority to the estimation of urea percentage and urea in cgm., and especially the experimental polyuria test, this was true only as an index of the total kidney function, not of the relative function of the kidneys as compared with each other. (2) They had found that in eight out of fourteen cases ureteral catheterism so diminished the output of phenolsulphonephthalein as to render it most misleading as regarded the total kidney capacity; although, as they had observed, the relative inefficiency of the diseased kidney as compared with its mate was correctly indicated by the test. (3) In eight out of ten ureter catheter examinations in which phenolsulphonephthalein output was compared with the urea in cgm., the two told the same tale, while the two cases in which they differed were better diagnosed by comparison of successive specimens obtained by ureter catheter than by any evidence derived from single specimens. Hence they deemed it advisable usually to make two phenolsulphonephthalein tests, one with ureter catheterism and one without, just as they made two urea tests, one with ureter catheterism and one on a twenty-four-hour specimen of urine. The microscopic findings remained as ever the most important elements in ureter catheter diagnosis. Other tests should confirm these. The phenolsulphonephthalein test was not to be depended upon as an absolute or infallible guide of the actual renal function or of the reserve force of the kidneys to withstand the shock of nephrectomy any more than any other test.

The Phenolsulphonephthalein Test for Estimating Renal Function.—Dr. J. T. Geraghty and Dr. L. G. Rowntree presented this communication, which was a résumé of their experience with this test during the past two years and dealt particularly with its value in relation to nephritis. They described the technique which they employed and which they had improved since they made the earlier experiments. Excretion had been studied in several hundred normal individuals. In their earlier work they had used the subcutaneous administration exclusively, but recently they had employed the intramuscular and intravenous methods. The time of appearance following

the intramuscular administration was practically the same as after the subcutaneous, but the output averaged from 5 to 10 per cent. more for the first hour. Following the intravenous injection the drug normally appeared in from three to five minutes, and from 50 to 60 per cent of the drug was eliminated in the first half hour, and 63 to 80 per cent. during the first hour. With this method observations for a half hour only should be employed. For general use they advocated the subcutaneous or intramuscular methods, the latter particularly when edema was present. They concluded that: (1) The phenolsulphonephthalein as used by them had many advantages over all other functional tests so far proposed. (2) It was better adapted for use as a functional test than any other drug previously employed for the same purpose, on account of its early appearance in the urine and the rapidity and completeness of its elimination by the kidneys and the reliance to be placed on its findings. (3) The method of quantitative estimation of the amount of drug excreted was simple and exceedingly accurate. (4) It was of immense value from a diagnostic and prognostic standpoint in nephritis, as it revealed the degree of functional derangement in nephritis, whether of the acute or chronic variety. (5) In the cardiorenal cases so far studied the test had proven of value in determining to what degree renal insufficiency was responsible for the clinical picture presented. (6) The test had proven of value not only in diagnosing uremia from conditions simulating it, but had also successfully indicated that uremia was impending when no clinical evidence of its existence at the time was present. (7) The test had proven of great value in revealing the true renal condition in cases of urinary obstruction. It was here of more value than the urinary output, total solids, urea, or total nitrogen, and enabled the surgeon to select a time for operation when the kidneys were at their most favorable functional condition. The improvement in the renal condition in cases of urinary obstruction following the institution of preliminary treatment was strikingly indicated by this test. (8) In unilateral and bilateral kidney disease the absolute amount of work done by each kidney as well as the relative proportion could be determined when the urines were obtained separately. They did not feel that this was always mathematically accurate, but in their series it had indicated the functional capacity to a degree not attainable by other tests.

Some Recent Advances in the Diagnosis of Renal Pain.—Dr. Hugh Cabot of Boston read this paper. He said that he wished to call attention to the status of the newer methods of diagnosis in moninflammatory conditions of the kidney and to point out the extent to which our advance in knowledge had added to the responsibility of those who would undertake the care and management of these conditions. The kidney was not an organ which adapted itself readily to the exploratory methods of the surgeon. There were now few conditions which justified an operation upon the kidney properly spoken of as exploratory, and they were entitled to demand of the surgeon who attempted renal surgery that he be able to plan in advance the procedures necessary and to expose only such portions of the urinary tract as demanded treatment. Dr. Cabot divided the conditions of the kidney causing pain into three groups. First, those due to the presence of stone in the kidney or ureter. Second, those due to conditions other than stone which obstructed the flow of urine to the bladder. Third, sources of pain in the kidney region not due to conditions in or about the kidney. If stones were present in the kidney or ureter the following important facts should be known before operation: (1) The position of the stone, whether in the kidney or ureter. (2) The size of the stone. (3) Which part of the kidney the stone occupied so that it might be removed by opening the pelvis, in appropriate cases, or the proper calix should it lie without the pelvis. They were not justified in exploring the entire kidney in order to find a small stone in one calix and too frequently the kidney proper had been incised when the stone could have been removed with far less damage by opening the pelvis. (4) If the stone was in the ureter they should in most cases require a knowledge of the conditions above the stone, to what extent the ureter was dilated, and whether or not the stone could be removed through the opening made above it, thereby diminishing the risk of stricture. They might in most cases insist upon an accurate knowledge of the amount of damage to the kidney tissue and thereby enable an operator to select with great accuracy those cases in which the kidney should be removed rather than to leave it to haphazard judgment at the time of operation. The conditions other than stone belonging to the second group included cases of distinct hydronephrosis and also that far more obscure group most frequently occurring in subjects of movable kidney, in which it had been difficult to decide whether the kidney or some other viscera was the cause of trouble. No doubt many harmless vagrant kidneys had been anchored in an awkward position because they were movable rather than because they interfered with the patient's health. It was equally true that many had failed to get relief because the amount of mobility was apparently within normal limits. Moderate strictures of the ureter had been extremely liable to escape detection. The third group comprised a large number of cases in which the right rather than the left upper quadrant of the abdomen was involved, and in which only by searching methods of diagnosis could the kidney be excluded. In these cases accurate diagnosis was essential to accurate surgery. To explore the kidney when stones should have been taken from the gall-bladder was a blunder unjustifiable to-day. Dr. Cabot illustrated with lantern slides the methods necessary to obtain these facts, drawing largely from his own experience.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

Board of Medical Examiners, Florida.

November 9 and 10, 1910.

ANATOMY.

1. Describe the bony pelvis.
2. What are the three divisions of the skeleton of the foot? Name the bones comprised in each.
3. Describe the articulation of the hip-joint, and name its ligaments.
4. Name the visceral branches of the abdominal aorta.
5. Describe the brachial artery and give its relations.
6. Name and describe the membranes enveloping the brain.
7. Describe the sinuses of the dura mater.
8. Give the origin, function and general distribution of the 5th cranial nerve.
9. Describe the mediastinum.
10. Describe the diaphragm and name its openings.

PHYSIOLOGY.

1. What are the causes of the variation in the rate and strength in the heart beat?
2. Describe the digestion of fat, and how and where is it mixed with the blood.
3. What are the constituents of bile as secreted by the liver?
4. Describe the difference and the cause of the difference between an anterior and a posterior spinal nerve root.
5. Which of the cranial nerves contain afferent nerve fibers?
6. What part of the brain is responsible for co-ordination of muscular movements, i. e., maintaining equilibrium?
7. What is the difference in the blood of the renal artery and the renal veins?
8. What is the effect of stimulating the superior laryngeal nerve?

9. What is the difference between nucleo-albumins and nucleo-proteins?
10. What is phagocytosis?

CHEMISTRY.

1. Define the terms distillation, sublimation, porosity, osmosis, and element.
2. What is a definite compound?
3. What are the physical properties of hydrogen di-oxide? Give its formula.
4. Mention the antidote for arsenical poisoning, and how prepared.
5. Describe the flame test for sodium salts, and mention characteristic color.
6. Give antidotes, both local and constitutional, for carbolic acid poisoning.
7. Mention two good tests for albumen in the urine, and describe their application.
8. What is the most common salt found in the urine?
9. Describe the method of applying Haines' test solution for sugar in the urine.
10. Describe treatment of poisoning by silver nitrate in solution.

MATERIA MEDICA—THERAPEUTICS.

1. State the antidote to practically all alkaloids, explaining its action.
2. Give the official name and the minimum poisonous dose of strychninæ sulphas, morphinæ sulphas, and chloral. Give the antidote for each.
3. Name the preparations of belladonna, describe the toxic effects and give antidote.
4. How is opium obtained? What per cent of morphine should it nominally yield? Name two alkaloids of opium and give antidotes.
5. Explain the difference between the physiological action and the therapeutical use of medical agents.
6. What is cumulative action? Name one drug that has this tendency and give symptoms of such action.
7. What are the principal therapeutic uses of the preparations of mercury?
8. In what diseases are preparations of arsenic useful?
9. What is the dose of Fowler's solution and what precautions should be observed in its administration?
10. What are the principal alkaloids obtained from cinchona bark and used in medicine?

OBSTETRICS.

1. Give the anatomy of the uterus, including size, shape, location, and suspensory ligaments.
2. Define puberty, menstruation, menopause.
3. Define ectopic gestation. Does it ever result in a living child?
4. What is meant by the 1st, 2nd and 3rd stages of labor?
5. Give diagnosis and treatment of placenta prævia.
6. Define mastitis.
7. Give best methods of removing placenta.
8. What is phlegmasia alba dolens? Its cause?
9. What is the difference between position and presentation of the fetus?
10. What changes take place in the structure of the uterus after delivery?

GYNECOLOGY.

1. Give indications and contra-indications for the use of the curette.
2. State under what conditions hysterectomy for cancer of the uterus is not justifiable; how determined, and give treatment in inoperable cases.
3. Give symptoms, diagnosis, and differential diagnosis for submucous fibro-myoma.
4. Give causes, symptoms and treatment for various forms of dysmenorrhea.
5. Differential diagnosis of ascities from ovarian cyst.
6. Describe in detail operation for complete laceration of perineum, involving recto-vaginal septum.
7. Describe operation for removal of intraligamentous myoma.
8. Give description as to treatment of abscess of the cul-de-sac of Douglas.
9. Give symptoms of pelvic hematocele.
10. Outline symptoms of torsion of pedicle of ovarian cyst.

SURGERY.

1. Name the agents most employed for general anaesthesia and tell what are contraindications for use of those named.
2. Describe aseptic and antiseptic methods of treating wounds.
3. Give treatment of gunshot wounds of the abdomen.
4. What is an abscess?
5. What is aneurysm and how would you diagnose from abscess?
6. Describe a method of reducing a dislocation of the inferior maxillary bone.
7. Give symptoms and treatment of fracture of the ribs.
8. How would you treat a compound comminuted fracture of the femur at the middle third?
9. Give symptoms and treatment of stone in bladder.
10. Give indication for tracheotomy and describe operation.

ANSWERS TO STATE BOARD EXAMINATION QUESTIONS.

BOARD OF MEDICAL EXAMINERS, FLORIDA.

November 9 and 10, 1910.

ANATOMY.

1. See Cunningham's "Anatomy" (1910), pages 212 and 219; or Gray's "Anatomy" (1910), page 215.
2. The foot consists of (1) *Tarsus* (os calcis, astragalus, cuboid, scaphoid, internal, middle, and external cuneiform); (2) Five *metatarsal* bones; and (3) Fourteen *phalanges.*
3. The *hip-joint* is an enarthrodial joint formed by the head of the femur and the acetabulum. The articular surfaces are covered with cartilage. Near the center of the head of the femur is attached the ligamentum teres. The *ligaments* are: (1) The capsular, which embraces the margin of the acetabulum above, and the neck of the femur below. (2) The ileofemoral or Y ligament, which passes obliquely across the front of the joint, and is attached above to the anterior inferior spine of the ileum, and below to the anterior intertrochanteric line. (3) The ligamentum teres. (4) The cotyloid ligament, which deepens the acetabulum, and bridges over the cotyloid notch, being there called (5) the transverse ligament. The joint has a very extensive synovial membrane. It is capable of the following movements: Flexion, extension, abduction, adduction, circumduction, and rotation.
4. The *visceral branches of the abdominal aorta* are: Celiac axis (Gastric, Hepatic, Splenic), Superior Mesenteric, Inferior Mesenteric, Suprarenal, Renal, Spermatic or Ovarian.
5. See Cunningham's "Anatomy" (1910), page 830; or Gray's "Anatomy" (1910), page 642.
6. See Cunningham's "Anatomy" (1910), page 597; or Gray's "Anatomy" (1910), page 966.
7. See Cunningham's "Anatomy" (1910), page 883; or Gray's "Anatomy" (1910), page 723.
8. FIFTH CRANIAL NERVE. *Origin:*—(1) *Superficial,* from the side of the pons varolii; (2) *Deep* (sensory root) from the medulla, and upper part of cord; (motor root) from floor of fourth ventricle, and side of the aqueduct of Sylvius.

Distribution and Function: First, or *ophthalmic branch* supplies sensation to conjunctiva and skin of upper eyelid, cornea, skin of forehead and nose, lachrymal glands, mucous membrane of nose. *Second,* or *superior, maxillary branch* supplies sensation to skin and conjunctiva of lower lid, nose, cheek, upper lip, upper teeth and alveolar processes, and palate. *Third,* or *inferior maxillary, branch* supplies sensation to external auditory meatus, side of head, mucous membrane of mouth, anterior two-thirds of tongue, lower teeth, lower lip, and skin of the lower part of the face. This branch, in addition, supplies motion to the muscles of mastication (masseter, temporal, external pterygoid, internal pterygoid), also to mylohyoid and anterior belly of digastric.

9. See Cunningham's "Anatomy" (1910), page 976; or Gray's "Anatomy" (1910), page 1187.
10. The *diaphragm* is a musculofibrous septum which divides the thoracic from the abdominal cavity; it is fan-shaped; the broad elliptical portion is horizontal, and the crura are vertical. It is attached to the ensiform, to the internal surfaces of the lower six costal cartilages, to bodies and intervertebral substances of first, second, and third lumbar vertebræ. Its *openings* are: (1) The aortic, transmitting the aorta, vena azygos major, and the thoracic duct; (2) the esophageal, transmitting the esophagus, pneumogastric nerves, and some small esophageal arteries; (3) the opening for the vena cava, transmitting the inferior vena cava, and small branches of the right phrenic nerve; (4) the right crural, transmitting the right splanchnic nerves; (5) the left crural, transmitting the left splanchnic nerves and the vena azygos minor.

PHYSIOLOGY.

1. *Variations in the rate and strength of the heart beat* may depend on: Age, sex, weight, food, drink, exercise, posture, quantity of blood, nervous influences.

2. Fat is digested in the small intestine by the *bile*, which emulsifies and saponifies it, and by the *steapsin* of the *pancreatic juice*. Fats are absorbed by the lymph vessels of the small intestine, which converge to empty into the thoracic duct; this latter empties into the blood circulation at the union of the left internal jugular and subclavian veins.

3. Bile is composed of: Water, sodium glycocholate, sodium taurocholate, bile pigments (biliverdin, bilirubin), cholesterin, fat, mucus, and inorganic salts.

4. "The *anterior roots* contain centrifugal fibers—motor fibers, vasomotor fibers, sweat, and inhibitory fibers of the splanchnics. The motor fibers take their origin in the cells of the anterior horns, while other centrifugal fibers are united to the cerebral cortex. As to the vasomotor fibers they have their centers of origin in the medulla oblongata and cord to penetrate the anterior roots. They probably do this without entering into communication with the cells of the anterior horns.

"The *posterior roots* have centripetal reflex fibers. These leave the skin, muscles, and other organs; penetrate the spinal cord, and are in direct connection with the reflex centers located partly in the cord itself and partly in the medulla oblongata, pons, corpora quadrigemina, cerebellum, and optic thalami. The other sensory and sense fibers penetrate the cord by way of the posterior roots to ascend toward the cerebral cortex. Here are received the several conscious sensations: touch, pressure, temperature, pain, and muscular sense." (Ott's *Physiology*.)

5. *Afferent nerve fibers* are found in the 1st, 2nd, 5th, 8th, 9th, and 10th cranial nerves.

6. The cerebellum.

7. The blood in the renal artery contains more water, more urea, more uric acid, more oxygen, more carbon dioxide, more mineral salts, and less albuminoids than the blood in the renal vein.

8. Stimulation of the superior laryngeal nerve produces slowed or inhibited respirations and a tendency toward expiration.

9. *Nucoalbumins* do *not* have nucleic acid and xanthine bases as decomposition products; *nucleoproteids* do have these as decomposition products.

10. *Phagocytosis* is the faculty of certain cells (notably the mononuclear and polynuclear leucocytes) to take up and destroy bacteria.

CHEMISTRY.

1. *Distillation* is the process of converting a liquid to a vapor, and then by condensation restoring the vapor to a liquid.

Sublimation is the process of converting a volatile solid to a vapor and then condensing the latter.

Porosity is the condition of being porous (or having pores).

Osmosis is the passage of liquids and substances in solution through a porous membrane.

Element is a substance which cannot by any known means be split up into dissimilar substances.

2. A *compound* is a substance made up of two or more elements, chemically united, in definite proportions.

3. Hydrogen dioxide is a syrupy liquid, colorless, odorless, with a metallic, astringent taste, miscible with water, an oxidizing and bleaching agent, a disinfectant and antiseptic. *Formula:* H_2O_2.

4. The *antidote for arsenical poisoning* is freshly prepared solution of ferric hydroxide. It is prepared by mixing 40 c.c. of solution of ferric sulphate with 125 cc. of water, and keeping the liquid in a large well-stoppered bottle. Rub 10 grams of magnesium oxide with cold water to a smooth and thin mixture, transfer this to a bottle capable of holding about 1000 c.c. and fill it with water to about three-fourths of its capacity. When the preparation is wanted for use shake the magnesium oxide mixture to a homogeneous, thin magma, add it gradually to the diluted solution of ferric sulphate, and shake them together till a uniform, smooth mixture results. (U. S. P.)

5. A fragment of a solid, or a drop of solution is placed on a sterile platinum wire and introduced into a Bunsen flame; the presence of sodium is indicated by an intense yellow color.

6. Alcohol, soluble sulphates such as magnesium sulphate or sodium sulphate, white of egg, lavage.

7. *Two reliable tests for albumin in the urine:* "The urine must be perfectly clear. If not so, it is to be filtered, and if this does not render it transparent it is to be treated with a few drops of magnesia mixture and again filtered."

I.—*The heat test:* "The reaction is first observed. If it be acid, the urine is simply heated to near the boiling point. If the urine be neutral or alkaline, it is rendered *faintly* acid by the addition of dilute acetic acid, and heated. If albumin be present, a coagulum is formed, varying in quantity from a faint cloudiness to entire solidification, according to the quantity of albumin present. The coagulum is not redissolved upon the addition of HNO_3."

II.—*Heller's modification of the nitric acid test:* "Place in a test-tube a layer of HNO_3 about 2 cm. in thickness, then, with a pipette, carefully float upon the surface of this a layer of the urine in such a manner that the liquids do not mix. If albumin be present, a cloudy ring appears *at* the point of juncture of the two layers, the borders of the cloud being sharply defined. A cloudy ring may be formed by the presence of an excess of urates, but in this case it is not *at*, but *above*, the point of junction of the layers, and its upper border is not sharply defined, but fades off gradually."—(Witthaus' *Essentials of Chemistry*.)

8. Sodium chloride.

9. *Haines' test for sugar in the urine:* Gently boil a few c.c. of Haines' solution in a test tube, add drop by drop six or eight drops of the urine, boil gently for a moment only; if a yellow or red precipitate does not appear sugar is absent.

10. Give solution of common salt (sodium chloride), and follow with an emetic.

MATERIA MEDICA AND THERAPEUTICS.

1. Tannin is the antidote; with the alkaloid it forms a tannate which is comparatively insoluble.

2. Strychnine sulphate, probably 3 grains, chloral or chloroform. Morphine sulphate, probably 1 grain, potassium permanganate. Hydrated chloral, probably about 20 grains, strychnine.

3. *Preparations* of belladonna:—the extract, the fluid extract, tincture, ointment, the plaster, and the liniment. Atropine, with its oleate and sulphate, and homatropine hydrobromide.

Toxic effects: Dryness of the mouth and throat, thirst, drowsiness, dysphagia, face flushed, pupils much dilated, eyes prominent, numbness and partial paralysis of the extremities, and there may be delirium and coma.

Antidotes: There is no antidote; pilocarpin is the best physiological antagonist, and opium will counteract the effect on the pupils.

4. Opium is obtained by incising the unripe capsules of Papaver somniferum. It should yield not less than 9 per cent. of crystallized morphine. *Two alkaloids:* Morphine and codeine. *Antidotes:* Potassium permanganate, strychnine, amyl nitrite, atropine.

5. *Physiological action* is the influence which a drug exerts upon the various bodily organs or tissues in health; *therapeutic use* signifies, in some cases, the conditions in which the physiological action counteracts some abnormal process; in other cases, it is based upon empiricism, the drug having by experience been found useful in certain conditions, having no reference to its physiological action.

6. *Cumulative action* is the property which some drugs have of producing more or less sudden and violent action, after single and successive doses have been taken with no untoward effect. *Example:* Digitalis; this produces fast and irregular pulse, gastroenteritis, small pulse, low blood pressure.

7. *Mercury is used:* As an antiseptic, caustic, stimulating application, for parasitic and other skin affections, as a purgative, in inflammatory conditions, in diphtheria, syphilis, and other conditions.

8. *Arsenic is used:* In stomach disorders, bronchial and pulmonary affections, diabetes, diarrhea, anemia, chlorosis, chorea, malaria, and chronic skin diseases.

9. Dose of Fowler's solution is about 7 minims. It should be given diluted and after meals, and the dosage should be steadily reduced.

10. Quinine, quinidine, cinchonine, cinchonidine.

OBSTETRICS.

1. In the nulliparous adult the uterus is about three inches long, about two inches wide at the upper part, and about one inch thick. It is pear-shaped, and lies between the rectum behind and the bladder in front; it is below the abdominal cavity and above the vagina. Its position is one of slight anteflexion, with its long axis at right angles to the long axis of the vagina. The anterior surface of its body rests on the bladder, and the cervix points

backward toward the coccyx. The uterus is not fixed, but moves freely within certain limits. It is held in place by ligaments—broad ligaments, round ligaments, vesicouterine, rectouterine, ovarian, and uterosacral. The arteries are the uterine and ovarian; the nerves are from the uterovaginal plexus, the hypogastric plexus, and the vesical plexus.

2. *Puberty* is the period when the child becomes sexually mature; and, in the case of the female, when menstruation commences.

Menstruation is a periodical disturbance in the female, characterized by a bloody mucus discharge from the uterine cavity; it lasts during the period of woman's sexual activity, but is temporarily suspended during pregnancy and early lactation.

Menopause is the period when menstruation ceases.

3. *Ectopic gestation* is a pregnancy in which the ovum is developed outside of the uterine cavity. It sometimes results in a living child.

4. Labor is divided into three stages: The *first stage* begins with the commencement of labor, and ends with the complete dilatation of the os uteri. The *second stage* begins with a complete dilatation of the os uteri, and ends with the birth of the child. The *third step* immediately follows the second, and ends with the expulsion of the placenta and the beginning contraction of the uterus.

5. *Placenta prævia* is the condition in which the placenta is attached in the lower uterine segment, and may be near or over (partially or completely) the internal os. *Symptoms:* Sudden hemorrhage, accompanied by syncope, vertigo, restlessness, and feeble pulse. *Treatment:* Stop the hemorrhage by a vaginal tampon; this must be tight and thorough. *Accouchement forcé* is indicated; this consists of dilatation of cervix, version, and immediate extraction of the child.

6. *Mastitis* is inflammation of the mammary gland.

7. See Williams' "Obstetrics" (1909), page 298; or Hirst's "Obstetrics" (1909), page 343.

8. PHLEGMASIA ALBA DOLENS is a form of manifestation of puerperal sepsis in which there is a thrombosis of the iliac or femoral vein. Sometimes it occurs after a uterine phlebitis, in which clots are carried from the uterine sinuses to the hypogastric veins, where they cause obstruction to the blood flow in the crural veins. The trouble may also begin as a crural phlebitis. It is thus due either to cellulitis or to thrombosis. It usually appears about the third or fourth week of the puerperium.

9. By *presentation* is meant the part of the fetus which presents at the pelvic brim; examples—vertex, breech, face.

By *position* is meant the relation between a point on the fetus and a point on the maternal pelvis; examples—in a vertex presentation the position may be (1) left occipitoanterior, (2) right occipitoposterior, (3) right occipitoanterior, (4) left occipitoposterior.

10. See Williams' "Obstetrics" (1909), page 332; or Hirst's "Obstetrics" (1909), page 348.

GYNECOLOGY.

1. *Curettage is indicated:* (1) For removal of placental débris (2) in hemorrhagic endometritis, (3) in some forms of dysmenorrhea (membranous), (4) for diagnostic purposes, (5) in some cases of puerperal sepsis, (6) sometimes to check hemorrhage, due to fibroids. *Contraindications:* (1) The least suspicion of even the possibility of pregnancy; (2) menstruation; (3) acute endometritis; (4) malignant disease of the uterus or vagina; (5) acute pelvic inflammation.

2. "*Indications and Contraindications for Hysterectomy.* Hysterectomy is indicated if the disease is limited to the uterus. Such limitation will be inferred:—1. By the normal mobility of the uterus; 2. By the absence of any enlargement of the lymphatic glands in the parametria; 3. By the absence of the disease on the vaginal walls. Enlargement of the glands is evidence that the disease has extended beyond the uterus. This does not positively contraindicate hysterectomy, but renders the prognosis less favorable. Whether enlarged or not the glands should, if practicable, be removed. Extension of cancer to the vaginal walls, if slight, does not definitely contraindicate hysterectomy, provided the diseased portion of the vagina can be removed with the uterus. Extensive involvement of the vagina and fixation of the uterus in surrounding cancer contraindicate the operation.

"When the disease has passed beyond the hope of radical cure, but not beyond the limits of palliative hysterectomy, hysterectomy is sometimes performed for the temporary relief of symptoms; its benefits, however, are not usually sufficient to overbalance its dangers." (Dudley's *Gynecology.*)

Inoperable cases require deodorizing and cleansing douches; tampons (frequently removed) to check hemorrhage; morphine, for pain; regulation of bowels, kidneys; tonics, nutritious food, and mild exercise.

3. See Rose and Carless' "Surgery" (1908), page 1281.

4. DYSMENORRHEA. *Causes:* Pelvic congestion, pelvic inflammation, malnutrition, overwork, lack of development, neuralgia, stenosis, or obstruction of the cervix, prolapse, or displacement of the uterus. *Symptoms:* Pain, varying from malaise to agony; chiefly noticed before or during menstruation. There may be also tumor, inflammation, obstruction or malformation or malposition of the uterus. *Treatment:* If possible remove cause; attend to the general condition, hygiene, tonics, regular habits, etc.; curettage may be necessary, and may have to be repeated (perhaps more than once).

5.

ASCITES.	OVARIAN CYST.
1. Previous history of visceral disease.	1. No such history.
2. Enlargement comparatively sudden.	2. Gradual.
3. Face puffy; color waxy; early anemia.	3. Facies ovariana. Anemia absent, or later.
4. Patient on back, enlargement symmetrical; flat in front.	4. Asymmetrical until tumor is quite large; prominent in front.
5. Sitting up, abdomen bulges below.	5. No appreciable change.
6. Navel prominent and thinned.	6. Navel usually unchanged.
7. Fluctuation decidedly clear, diffuse throughout abdomen, but avoids highest parts in all positions, and always has a hydrostatic level.	7. Less clear; limited to cyst; not modified by change of position. No hydrostatic level.
8. Intestines float on top of fluid; hence percussion gives clear tympanitic note over the highest parts of abdominal cavity, and dulness in lowest parts for all positions—*i.e.* areas of resonance and dullness change with position.	8. No change in areas of dullness and resonance with change of position. Dullness over cyst. Clear resonant note in all parts beyond cyst limits, *i.e.* in flanks and toward the diaphragm.
9. Vaginal touch detects fluctuation, bulging into vagina.	9. Vaginal fluctuation less clear or absent.
10. Uterus in prolapsed location, but position unchanged. Size and mobility unchanged.	10. Uterus displaced forward or backward, or laterally by pressure of cyst.
11. Hydragogues and diuretics temporarily remove the fluid.	11. Medicines have no effect.
12. Fluid light straw color and thin. Coagulates spontaneously.	12. Fuid light or dark and of varying consistency; albuminous, but does not coagulate spontaneously; may contain colloid matter

—(From Dudley's *Gynecology.*)

6. See Williams' "Obstetrics" (1909), page 326; or Hirst's "Obstetrics" (1909), page 867.

7. See Rose and Carless' "Surgery" (1908), page 1282.

8. The abscess should be opened and drained through the vagina.

9. *Symptoms* are: Pain, which is sudden and severe, over abdomen and pelvis; nausea, cold perspiration, cold extremities, rapid and weak pulse, pinched features, and shock.

10. In *torsion of the pedicle of an ovarian cyst,* there will be: Sudden abdominal pain, growing worse as the abdomen becomes more tense and increases in size; if the sac ruptures the tenseness disappears; symptoms of peritonitis may appear.

SURGERY.

1. Ether, chloroform, and nitrous oxide.

Contraindications to use of nitrous oxide: Vascular degeneration; advanced heart disease; conditions in which muscular relaxation is required.

The following contraindications for ether and chloroform are from Hare's *Practical Therapeutics:* "Ether should not be used by inhalation in bronchitis or acute nephritis, because of its irritant properties; in peritonitis or gastritis, because it is apt to induce vomiting; in aneurysm or in the presence of marked vascular atheroma, be-

cause it may rupture a blood-vessel by raising arterial pressure; nor in diabetes, lest it produce diabetic coma, and if anemia is present and an examination of the blood shows that the homoglobin is below 50 per cent., the use of the drug should be avoided if possible.

"*Chloroform* is not to be used in cases of fatty heart or dilatation of the heart, in those with a known idiosyncrasy, nor in the so-called lymphatic persons with overgrowth of lymphoid tissues, as, for example, adenoids. In the latter case it is particularly apt to cause sudden death. In valvular disease of the heart chloroform may be used with caution, although ether is preferable. Given a case of valvular disease that must be subjected to operation, the chances are better with an anesthetic than without it, as the pain and mental shock are worse for the heart than is the anesthetic."

2. See Rose and Carless' "Surgery" (1908), pages 264 and 266; or Da Costa's "Surgery" (1908), pages 244 and 51.

3. See Rose and Carless' "Surgery" (1908), page 244, or Da Costa's "Surgery" (1908), page 821.

4. An *abscess* is a circumscribed collection of pus in a cavity of new formation.

5. An *aneurysm* is a pulsating sac, containing blood, and communicating with the lumen of an artery.

See Rose and Carless' "Surgery" (1908), page 311; or Da Costa's "Surgery" (1908), page 361.

6. See Rose and Carless' "Surgery" (1908), page 617; Da Costa's "Surgery" (1908), page 584.

7. See Rose and Carless' "Surgery" (1908), page 493; or Da Costa's "Surgery" (1908), page 475.

8. See Rose and Carless' "Surgery" (1908), page 481; or Da Costa's "Surgery" (1908), page 464.

9. *The symptoms of stone in the bladder* are: Increased frequently of micturition; pain at end of urination, chiefly felt at the end of the penis or in the neck of the bladder; the urine may contain pus, mucus, or blood; a "click" can be obtained by using a searcher or sound; examination by the cystoscope may reveal the presence of the stone.

The *treatment* consists in removing the calculus, by litholapaxy, or lithotrity, or lithotomy (suprapubic or perineal).

10. See Rose and Carless' "Surgery" (1908), page 914; or Da Costa's "Surgery" (1908), page 769.

BULLETIN OF APPROACHING EXAMINATIONS.

STATE	NAME AND ADDRESS OF SECRETARY	PLACE AND DATE OF NEXT EXAMINATION†	
Alabama*	W. H. Sanders, Montgomery	Montgomery	July 11
Arizona*	Ancil Martin, Phoenix	Phoenix	July 5
Arkansas	F. T. Murphy, Brinkley	Little Rock	Nov. 14
California*	Chas. L. Tisdale, 929 Butler Building, San Francisco	San Francisco	Aug. 1
Colorado	S. D. Van Meter, 1723 Tremont Street, Denver	Denver	July 4
Connecticut*	Chas. A. Tuttle, New Haven	New Haven	July 11
Delaware	J. H. Wilson, Dover	Dover	June 20
Dist. of Col'bia	Geo. C. Ober, Washington	Washington	July 11
Florida*	I. D. Fernandez, Jacksonville	Jacksonville	Nov 7
Georgia	T. H. Goss, Athens	Atlanta	
Idaho*	O. J. Allen, Bellevue	Boise	Oct. 3
Illinois	J. A. Egan, Springfield	Chicago	June 13
Indiana	W. T. Gott, Crawfordsville	Indianapolis	July 11
Iowa	G. H. Sumner, Des Moines	Des Moines / Iowa City	June 5 / June 8
Kansas	H. A. Dykes, Lebanon	Kansas City	June 13
Kentucky	J. N. McCormack Bowling Green	Louisville	
Louisiana	A. B. Brown, Cusach's Bldg.	New Orleans	May 18
Maine	F. W. Searle, Portland	Augusta	July 6
Maryland	J. McP. Scott, Hagerstown	Baltimore	June 20
Massachusetts*	E. B. Harvey, State House, Boston	Boston	July 11
Michigan	B. D. Harrison, 205 Whitney Building, Detroit	Ann Arbor	June 13
Minnesota	W. S. Fullerton, St. Paul	Minneapolis	June 20
Mississippi	S. H. McLean, Jackson	Jackson	
Missouri	Frank B. Hiller, Jefferson City	St. Louis	June 12
Montana*	Wm. C. Riddell, Helena	Helena	Oct. 3
Nebraska	E. A. Carr, Lincoln	Lincoln	
Nevada	S. L. Lee, Carson City	Carson City	Nov 6
N. Hampshire	Henry C. Morrison, State Library, Concord	Concord	July 6
New Jersey	H. G. Norton, Trenton	Trenton	June 20
New Mexico	J. A. Massie, Santa Fe	Santa Fe	July 10
New York	C. F. Wheelock, Univ. of State of New York, Albany	New York / Albany / Syracuse / Buffalo	June 27
N. Carolina	B. K. Hays, Oxford	Charlotte	June 14
N. Dakota	H. M. Wheeler, Grand Forks	Grand Forks	July 5
Ohio	Geo. H. Matson, Columbus	Columbus	June 6
Oklahoma*	J. W. Duke, Guthrie	Oklahoma	July 11
Oregon	B. E. Miller, Portland	Portland	July 3
Pennsylvania*	A. R. Allen, Carlisle	Philadelphia / Pittsburg	June 27
Rhode Island	G. T. Swarts, Providence	Providence	July 6
S. Carolina	H. H. Wyman, Aiken	Columbus	June 13
S. Dakota	F. W. Freyberg, Mitchell	Pierre	July 12
Tennessee	C. A. Abernathy, Pulaski	Memphis / Nashville / Knoxville	
Texas	J. D. Mitchell, Fort Worth	Austin	June 26
Utah	R. W. Fisher, Salt Lake City	Salt Lake City	July 3
Vermont	W. Scott Nay, Underhill	Montpelier	July 11
Virginia	R. S. Martin, Stuart	Richmond	June 21
Washington*	F. P. Witter, Spokane	Tacoma	July 4
W. Virginia	H. A. Barbee, Point Pleasant	Charleston	July 10
Wisconsin	J. M. Beffel, Milwaukee	Madison	July 11
Wyoming	J. B. Tyrrell, Laramie	Laramie	June 6

*No reciprocity recognized by these States.

†Applicants should in every case write to the secretary for all the details regarding the examination in any particular State.

Medicolegal Notes.

Injuries from Use of X-Ray Machine.—In an action for damages for personal injuries caused by the use of an *x*-ray machine the following facts appeared. In 1901 the plaintiff was treated by the defendant for enlarged lymphatic nodes or glands on both sides of the neck. The defendant cut them out. In 1903 bunches again appeared on the neck, one on the right side under the chin and the other on the right or left side, the evidence as to this conflicting. The defendant advised *x*-ray treatment. He himself administered the treatment three or four times, and afterwards it was administered, under his direction, as he says, by his office girl. It was administered twenty-five times in all. The plaintiff said it was administered three times a week for fifteen minutes each time; the defendant said twice a week for ten minutes each time. At each treatment the plaintiff was seated in a chair, her head thrown back, and turned somewhat to the right, so as to expose the neck and under part of the chin. Her face as low as the lips was protected from the *x*-rays by a sheet of lead. The tube of the machine was placed somewhat to the left of the patient's neck, and 15 inches distant. The left side of the neck, therefore, where the plaintiff says there was no bunch, was nearer to the tube than the affected parts were. An unintended result of this treatment was a very severe and greatly disfiguring *x*-ray burn on the left side of the plaintiff's neck and lower part of the face, for which she sought to hold the defendant legally responsible. The jury gave a verdict for the plaintiff, which was not disturbed on appeal.

A physician, said the court, contracts with his patient that he has the ordinary skill of members of his profession in like situation, that he will exercise ordinary or reasonable care and diligence in his treatment of the case, and that he will use his best judgment in the application of his skill in the case. But he is not an insurer. He does not warrant favorable results. If he possesses ordinary skill, uses ordinary care, and applies his best judgment he is not liable even for mistakes in judgment. Medical science is not yet, and probably never can be, in many respects an exact, certain science. The practitioner cannot be expected to know, or be bound to diagnose correctly, that which is unknowable, as many hidden ailments are. The burden is on the plaintiff to show a malpractice.

In this case it was conceded that the defendant was a physician of great learning and skill. There was no controversy about that. It was shown that the *x*-ray treatment cannot be administered according to fixed and unvarying rules. All the medical witnesses concurred in saying that it is necessary to watch for the manifestation of burning during the entire period of treatment; that the treatment should be adjusted to the person and the exigencies of the case. The physician might vary or temporarily discontinue the treatment. He must watch, examine, and use his best judgment. That was what the plaintiff said the defendant did not do. The defendant said that he did.

The responsibility of the defendant must be considered with reference to the science of *x*-ray treatment as it was understood in 1903, when the treatment was given. There was testimony that great advances have been made in *x*-ray knowledge since 1903. But in 1903 the defendant knew that *x*-rays could burn, and of the need of watchfulness to detect the signs of burning. It was a question which version of the facts the jury adopted. And unless the jury were not warranted in believing that version the court could not interfere, and there was nothing inherently improbable or inconsistent in the plaintiff's story.—Coombs v. King, Maine Supreme Court, 78 Atl., 468.

Hypothetical Question as to Senile Impotency Admissible.—On a trial for assault with intent to commit rape and taking and detaining a female unlawfully with intent to compel her to be defiled, where the defense is that the defendant is suffering from senile impotency, and hence incapable of forming the intent necessary to constitute either offense, a medical expert may testify as to whether or not, in his opinion as an expert, the conduct of the defendant, set out in a hypothetical question, indicated senile impotency.—Territory v. Pierce, Supreme Court of New Mexico, 113 Pac., 591.

Books Received.

The MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading, but it must be with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

Absorption of Drugs.—W. E. Dixon points out that the rate of absorption of drugs from the alimentary canal may be influenced by the administration of other substances, either previously or simultaneously. Alcohol is not only absorbed with great rapidity itself from the stomach and intestines, but it facilitates the absorption of other substances dissolved in it. This naturally leads one to speculate whether this action of alcohol may not account for some of the toxic effects associated with indulgence. One fact is clear that alcohol is not the direct cause of the various cirrhoses which are commonly associated with alcoholics. But may it not be that in a proportion of these people poisonous products are formed in the alimentary canal as a result of putrefaction, and that the presence of alcohol brings about their absorption? Whether this explanation be correct or not, one such poisonous product is formed in the alimentary canal of man under certain conditions and its injection into animals leads to cirrhoses.—*Practitioner.*

Health Reports.—The following cases of and deaths from smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended May 26, 1911.

STRETCHING OF THE PYLORUS IN BENIGN STENOSIS.*

By MAX EINHORN, M.D.,

NEW YORK,

PROFESSOR OF INTERNAL MEDICINE AT THE NEW YORK POSTGRADUATE MEDICAL SCHOOL.

In two previous publications† I have shown that the pylorus can be reached without difficulty by instruments and can be treated in a similar manner as the cardia. Cases of ischochymia in which the pylorus was stretched were fully described. Most of them were due to pylorospasm, but in a few a benign stenosis must have existed. In the present paper I shall deal mainly with this latter affection.

Benign stenosis of the pylorus is met with in all stages of life. Infants, however, and adults show a greater predilection for this affection than persons during the period of adolescence. I shall first broach the subject of congenital stenosis of the pylorus and its mechanical treatment by stretching.

Congenital stenosis of the pylorus gives rise to symptoms soon after birth (within two or three weeks or somewhat later). There is vomiting with arrest of further development present. I had observed three cases of this kind, one described in the *Illinois Medical Journal* and two new ones which I shall report further on in this paper. In some instances this condition is due to a real stenosis, slight and combined with spasm, or to advanced stenosis with tumor formation.

The differential diagnosis is not always easy. The instruments used for this purpose in grown individuals can be utilized with some slight modifications for infants. Their application is comparatively easy.

It may not be superfluous to describe briefly the mode of procedure. The infantile duodenal bucket (6 mm. long and 13 mm. circumference), or the infantile duodenal metal olives (13 F., 12 F., and 11 F.) are attached to a braided silk thread of about 27 inches length. The bucket or the olive is dipped into warm water, then introduced into the pharynx of the infant. While the physician holds the end of the thread, the little patient is given either the breast or a bottle with milk. During the act of feeding the instrument very quickly moves down into the stomach. The end of the thread is now attached to the outer garment of the infant not far from the mouth. The hands of the infant are wrapped up in such a manner that it cannot pull at the string. The instrument is then left in the digestive tract for several hours (two to six), or over night. Meanwhile the infant's feeding is kept up in the usual manner. Attention is paid to the length of the thread hanging out this side of the mouth. If enough has slipped in to reach the duodenum, a slight pull on the thread is exerted in order to ascertain whether some resistance can be felt. The latter being present, there is a probability that the olive has passed the pylorus. When there is no resistance it is best to leave the instrument in its place for some time longer.

Before withdrawing the olive a knot is made at the lips of the patient, so that the length of the thread within the digestive tract can be gauged exactly. If the olive had passed the pylorus and was beyond Vater's papilla there is a golden yellow discoloration of the thread at the olive and for some distance above it—according to the length of the thread in the duodenum—while the parts lying in the stomach and esophagus retain their whitish color.

Inasmuch as the distances from the lips to the cardia and pylorus will greatly vary in different sized infants, it is well to determine approximately the location of the cardia and pylorus in each individual case. This is done as follows: The end of a string is held at the left corner of the child's mouth, carried from here crosswise to the angle of the jaw, then straight downward to the ensiform process. The length of the string to this point gives the distance of the cardia. If we add to this the length of the line running horizontally from the ensiform process to the right mammillary line, the distance of the pylorus is approximately given. It is self-understood that these are but rough estimates of the location of the two orifices (cardia and pylorus), and serve as a preliminary guide.

The length of the withdrawn thread from the knot to the olive is measured, also the distance from the knot to the beginning yellow discoloration, if such exists, and these measurements are compared with the gauge for cardia and pylorus previously ascertained in the given case. In this way it is possible to state positively whether the pylorus is permeable for the size of the olive used, and thus the differential diagnosis is greatly facilitated.

When a congenital stenosis of the pylorus is found—no matter whether due to mere pylorospasm or to a real stenosis—stretching of the outlet should be attempted. This can be done either by the infantile pyloric dilator (resembling the pyloric dilator for grown persons, only much smaller) or by the infantile inflatable dilating pyloric catheter (see Fig. 1). The latter instrument has mainly been used in infants.

Mode of Application.—The infant is given one of the duodenal olives attached to a silk thread (about 25 inches long), either the night previous to the stretching or about six hours ahead. Three to four hours after the last feeding, the stretching,

*Read before the American Gastroenterological Association, on April 19, 1911, at Philadelphia, Pa.

†Einhorn, Max: "Dilatation of the Stomach and Chronic Benign Tschochymia," *Illinois Medical Journal*, June, 1910; "On Pylorospasm," Medical Record, Jan. 21, 1911.

provided the olive has reached the duodenum, is performed as follows:

The fastened thread is cut off near its outer end and pulled through the eye of the dilating catheter. The latter is pushed with the right hand into the mouth, esophagus, and stomach along the thread, which is held securely by the left hand. This procedure must be performed gently. The catheter is then pushed still further until a resistance is encountered which cannot be overcome (this generally occurs at the angle of the duodenum "ramus horizontalis"). At this point the balloon of the catheter is filled up with air by means of a syringe. The instrument is then drawn somewhat forward until it meets with the pyloric resistance. Here it is slightly deflated, so that the balloon can pass the pylorus by a gentle pull. After reaching the stomach there is no resistance felt when withdrawing the instrument until meeting the cardia. The balloon is now completely deflated and the instrument as well as the olive and the thread are withdrawn. By noting the points at which the catheter met the two resistances (pylorus and cardia) the exact distances of these two orifices can be calculated.

Fig. 1.—The infantile pyloric dilating catheter, with infantile duodenal olives.

I now take pleasure in reporting two new cases of congenital stenosis of the pylorus. In both a relative real stenosis of the pylorus seems to have existed.

Case I.—December 13, 1910, Mildred S., 3½ months old, weight at birth eight pounds and a half. When two months old she weighed eleven pounds and two ounces. She now began to vomit after each feeding and her bowels were loose. The feeding was reduced to about four ounces of the mother's breast milk every four hours. Her stomach was usually washed out daily or every other day. When lavage was practised four hours after the last feeding the stomach would always contain about two ounces of milk and some mucus. From October 24 to December 13, or for about seven weeks, there was no gain in weight (about eleven pounds), and the symptoms persisted unabated. Dr. Kerley, who kindly referred the infant to me, made the probable diagnosis of a slight stenosis of the pylorus. The distance of the cardia from the lips was approximately six inches, and that of the pylorus eight inches.

I introduced the duodenal olive (13 F.) on a silk thread into the stomach of the infant on December 13 about 6 P. M. and left it in the digestive tract until Decemer 14 at 9 A. M. When pulling at the string there was no resistance to be encountered. The olive was withdrawn from the stomach and inspection of the thread showed no trace of a bile stain. The olive, therefore, did not pass the pylorus, notwithstanding it had been left in the stomach for fifteen hours.

On December 14 at 10 A. M. olive No. 11 F. was introduced and left in the digestive tract for six hours. A resistance was distinctly felt when the thread was gently pulled. This appeared to indicate that the olive was lodged in the duodenum. The thread was now pushed through the holes of the pyloric dilating catheter and the latter instrument introduced along the thread into the duodenum. After inflating the balloon and pulling the catheter somewhat forward a distinct resistance was felt at the pylorus. The balloon was then partly deflated and with gentle force I succeeded in drawing the catheter through the pylorus into the stomach. The balloon was then entirely deflated and the catheter as well as the olive were easily withdrawn. On inspection of the thread it was found bile stained at the end toward the olive.

Soon after the stretching the infant began to improve, the vomiting stopped and the stomach, on washing, was found to contain no milk. The little patient made a perfect recovery. It is now about 6 months old, and weighs fifteen pounds and is completely well.

Case II.—January 13, 1911, Sanders K., 13 weeks old, weighs five pounds and five ounces. The infant when born weighed about seven and a half pounds. When two weeks old patient began to vomit almost after every feeding and showed a steady loss. Dr. Sill was kind enough to refer the infant to me. It was emaciated in the highest degree. The stomach was found dilated, showing distinct peristaltic restlessness. The diagnosis of congenital pyloric stenosis (either real or spastic) was made by Dr. Sill and myself.

According to outside measurements, the distance from the lips to the pylorus appeared to be approximately eight inches. The duodenal olive (11F.) was introduced into the stomach by giving the little patient the bottle. The length of the thread was 27¼ inches. After five and a half hours

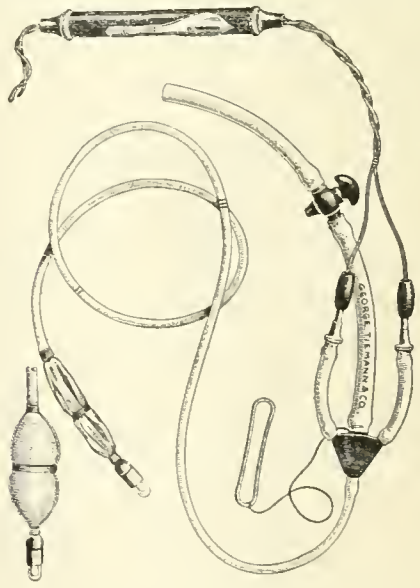

Fig. 2.—The pyloric dilator and diaphane.

there were twelve inches of the thread outside of the mouth, so that 15¼ inches were within the digestive tract. Slight pulling showed some resistance. The dilating pyloric catheter was pushed over the thread into the stomach and then further until it met with an obstacle. Here the balloon

was inflated and pulled forward. At eight inches distance from the lips a strong resistance was encountered (pylorus), which could not be overcome. After deflating the balloon somewhat the pylorus could be passed.

On January 20, 1911, the same procedure was repeated. At eight inches the pyloric resistance was distinctly felt, and this organ was slightly stretched. The little patient rallied somewhat, but the vomiting reappeared, and after living about two weeks longer the child died.

I shall now consider the subject of stretching the pylorus in the adult. Regarding the method I refer to my previous paper cited above. I would like, however, to add that I have constructed an instrument "the pyloric-dilator and diaphane," which consists of a pyloric dilator with a tantalum lamp at the end (cold lamp). (See Fig. 2.)

The advantage of this instrument consists in the fact that it is possible to ascertain whether the end is in the stomach or duodenum by simply connecting it with a weak electric current and looking at the patient's abdomen in a dark room. The lamp being in the stomach, a large area on the left side of the abdomen appears luminous (stomach). When, however, the lamp is lodged in the duodenum, a faint light in a small, lengthy area appears to the right of the linea alba, while nothing is seen over the gastric region. It is self-understood that when using this instrument no food should be in the stomach, as it would obscure the picture. This new instrument was used in a few instances; in most cases, however, the original pyloric dilator without lamp was employed. I have thus far stretched the pylorus in four grown up patients with a moderate stenosis of this outlet. I shall describe three of them.

Case I.—October 10, 1910, Miss Elsa S., 25 years old; has always been delicate. About six years ago while abroad she took a powder and apparently, as it appeared to her, swallowed some glass from a broken bottle that was mixed with it. She was at once treated for this by ingesting plenty of bread and potatoes. From this time she dates her trouble, as she has never since felt well. After swallowing the glass she began to vomit, no food, but watery mucus in large quantities accompanied by high fever. These attacks occurred off and on during her stay abroad about six years ago. She then returned in October of that year to this country. Here she vomited for the first time a quantity of dark blood. She then got some medicine from a physician which stopped the vomiting (silver nitrate?). Whenever she stopped the medicine the vomiting returned. She therefore kept on taking it for a long time. Discomfort, nausea, and a bloating sensation over the gastric region existed almost all the time. Last summer she stopped the medicine entirely and she then for the second time vomited some clotted blood. She has always been constipated and subject to headaches. In the meantime she has been abroad several times, and has been treated for gastric ulcer by rest and diet.

Present condition.—The patient's skin looks dark gray, with a bluish hue (argyrosis). She complains of distress in the gastric region immediately after eating and of great flatulence with constipation. The epigastrium is tender to pressure. The stomach is markedly dilated, extending a hand's width below the navel. The gastric contents showed a normal acidity, but retention of food from the day before.

The duodenal bucket examination showed a brownish discoloration of the thread between 42-46 cm., while the end was golden yellow. The diagnosis of ulcer of the stomach and probably also beginning stenosis of the pylorus was made, and patient first put on duodenal alimentation for two weeks. A new test with the bucket after this period of treatment showed that the ulcer had almost entirely healed. The pyloric dilator was then introduced and the pylorus stretched and also measured. While at first (November, 1910) 40 F. could be pulled through with quite some difficulty, now (March, 1911), by gradual dilatation, 55 F. and even 62 F. can pass the pylorus smoothly.

The measurements of the balloon passing the pylorus were as follows:

1910.	Measure.	Weight.	1911.	Measure.	Weight.
Nov. 27,	4 cm.,	112	Jan. 4,	4¾ cm.,	116
Dec. 5,	4½ cm.,	117½	Jan. 10,	5 cm.,	
Dec. 12,	4½ cm.,	117¾	Mar. 21,	5.5 cm.,	
Dec. 19,	4¾ cm.,	118	Mar. 29,	6.2 cm.,	

As the patient was living in Detroit, Dr. Aaron was kind enough to perform the stretching once weekly. The patient has steadily improved. She has gained twenty pounds in weight. She enjoys most varieties of food without any discomfort.

Case II.—February 3, 1911. F. P. H., age 51, physician. Habits temperate. He had always been well and hearty until six years ago; during the summer of 1904 he was troubled periodically with attacks of indigestion and gastric pain, mild at first, and relieved by the ordinary digestive remedies. The attacks grew more frequent and severe, with gradual loss of flesh, until the late fall of 1904, when he had a slight gastric hemorrhage.

On November 30, 1904, he had a profuse hemorrhage, at which time he entered the German Hospital in New York City, and was there under my care. A marked dilation of the stomach with ischochymia was found. Patient improved steadily on a liquid diet and soon his stomach began to be empty in the fasting condition. After remaining a month at the hospital, patient returned home and continued to improve, attending to active practice of his profession until the following June, when he had another gastric hemorrhage. After a few days' quiet in bed, light diet, he began to improve, until he apparently grew well and hearty, having gained in weight so that he was heavier than at any previous time in life. This favorable condition remained for about five years, or until the summer of 1910, when a slight feeling of the old difficulty manifested itself. But with care in choice of food, manner of living, etc., he kept quite comfortable until about three months ago, or October, 1910, when a slight hemorrhage made its appearance again. Whereupon (February 2, 1911) he returned to the German Hospital and placed himself again under my care. At no time from the beginning of the trouble to the present was the hemorrhage profuse, with two exceptions, when he first entered the hospital (November 30, 1904) and seven months later (June, 1905). Appetite was always good, and, aside from the stomach, all bodily functions were performed in a normal manner.

Present symptoms: Had pain (acidity) in epigastrium daily, more especially two or three hours after meals, which would continue for two to three hours, either until the stomach was empty, or until an alkali or food was taken. The pain was most severe two inches to the right of the median line and a hand's width over the level of navel. Occasionally nausea

would occur, followed by vomiting. The physical examination revealed a markedly dilated stomach extending a hand's width below the navel. There was peristaltic restlessness of the organ visible. The gastric contents showed the presence of free HCl and a high acidity equal to 80 with food remnants from the previous day. After a test supper of rice, gastric lavage performed the following morning in the fasting condition revealed the presence of a considerable amount of rice and gastric juice and some bile. The duodenal bucket passed through the pylorus and failed to show a blood stain. The pyloric dilator was then introduced, on February 6, 1911, at bed time. The following morning it was found that it had passed the pylorus. Upon filling up the balloon a resistance was encountered at about 62 cm. from the lips; after slight deflation this spot was passed and the balloon could be easily dragged forward up to the pylorus. Here, or at about 56 cm. from the teeth, another strong resistance was met. The balloon had to be still further deflated; 40 F. passed with difficulty. The first resistance in the duodenum must have been due to spasmodic contraction, for I have never again encountered it, while the pylorus seems to have been narrowed. For at each stretching we succeeded in passing a somewhat larger balloon, as the following figures show: February 7, 40 F.; February 10, 48 F.; February 12, 53 F.; February 21, 57 F.

Soon after instituting the stretching of the pylorus the patient began to improve. The visible peristalsis disappeared; patient felt no discomfort, and his stomach, after a previous test supper of rice, proved to be perfectly empty on the following morning. On February 21, before leaving the hospital, patient had gained five and a half pounds in weight during his short stay of eighteen days.

Case III.—March 2, 1911. Miss Jean C., 36 years old; has always had some digestive disturbances since early childhood. About fifteen years ago patient had a severe attack of vomiting, lasting a few days, followed by hematemesis. Patient then felt quite well for a few months, when an attack of gastric pains and vomiting would supervene. At such a time patient could not even bear the weight of her clothes on her stomach. These attacks continued to appear every two or three months. They would be relieved and cut short by abstaining from all kinds of food and drink for from two to three days. Nourishment, even liquid, would prolong the attack.

In March, 1910, patient had a severe attack, accompanied by several gastric hemorrhages (hematemesis). In June, 1910, the patient had another spell of vomiting of blood. About the end of February, 1911, the patient again had a period of vomiting lasting an entire week, accompanied by hematemesis and melena. Several times during this spell patient fainted.

Present condition.—The patient feels extremely weak and suffers from pains after the ingestion of food, followed by vomiting. Examination of the abdomen reveals tenderness over the epigastric region. The stomach is dilated, extending three or four fingers' width below the navel. In the pyloric region an indistinct resistance can be felt which is painful to pressure, and which was presumed to be a spasmodically contracted pylorus. The right kidney is movable in the first degree.

The duodenal bucket was given on March 3 at 9 P. M. and removed on the following morning about 8 P. M. The thread showed a brownish stain at about 57 cm. from the lips and the end was golden yellow. The bucket contained a yellowish fluid of an alkaline reaction. The bucket test, therefore, showed that the ulcer was just beyond the pylorus at the beginning of the duodenum, and that the pylorus was permeable for the bucket or over 23 F.

The patient was put on duodenal alimentation for two weeks and given two grams of subnitrate of bismuth three times daily. She felt very comfortable during the entire time. The bucket test was then repeated on March 19, and the thread showed no trace of any brownish discoloration. The ulcer appears to have healed. The pyloric dilator was then introduced on March 20 at 9 P. M. and the pylorus stretched and measured on the following morning. It was found that 38 F. could be pulled through with slight force. The stretching was repeated on March 28.

In the first part of the paper it was shown that the pylorus can be stretched in infants without much difficulty. Cases of congenital stenosis thus treated will reap benefit from it, provided this measure is undertaken before they are in the last stages of marasmus. The second part of the article is devoted to the treatment of real benign stenosis of the pylorus in grown patients in its beginning stage by stretching. In order to be suitable for this mode of treatment the following two conditions must obtain: (1) There should be no active ulceration in the pylorus or in its immediate vicinity. (2) The stricture must not be too far advanced. Most appropriate for this mode of treatment are those cases in which the duodenal bucket (23 F.) still passes the pylorus. If the pylorus is not any more permeable for the bucket, metal olives (17, 15, 13 F.), with a thread attached, may be tried in a similar manner as the bucket. In case one of them still passes the pylorus an attempt at stretching may first be undertaken with the dilating pyloric catheter* in very much the same way as described in the first part of the paper for pyloric stenosis in infants.

When the pylorus has been somewhat widened the ordinary pyloric dilator may then be employed. Cases in which fresh ulcerations in the pylorus or vicinity exist must first be subjected to some mode of treatment with the object of curing them. As soon as the thread test becomes negative, thus showing the absence of denuded mucosa, the pyloric dilator may be employed. Miss Jean C. (Case III) represents such an instance. Here first the ulcer was cured by means of duodenal alimentation and then the slightly stenosed pylorus was stretched.

The ideal way of treatment of benign stenosis of the pylorus consists in widening this outlet. This may be accomplished by stretching of the pylorus as above outlined, or when this is not any more possible (advanced stricture) by the Heinecke-Mikulicz or Finney's operations (pyloroplasty or gastroduodenoplasty).

Gastroenterostomy, which is the easier operation and most often practised, presents the disadvantage that the physiological relations between the stomach, pylorus, and duodenum are thereby more or less disturbed.

The internal means and the surgical measures for the treatment of benign pyloric stenosis are no rivals to each other, but rather work hand in hand. Where one ceases the other steps in, always harmonizing with each other.

*Einhorn, Max: "A New Method of Catheterizing the Pylorus and Duodenum," Medical Record, Oct. 9, 1909.

POLLUTION OF HARBOR WATER USED IN THE FREE FLOATING BATHS.*

By LINSLY R. WILLIAMS, A.M., M.D.,

NEW YORK.

ATTENDING PHYSICIAN, CITY HOSPITAL; ASSOCIATE IN MEDICINE, COLLEGE OF PHYSICIANS AND SURGEONS; MEMBER METROPOLITAN SEWERAGE COMMISSION.

Floating Bathing Establishments.—The floating bathing establishments of New York City, of which there were twelve during the season of 1909 and sixteen during the season of 1910, are constructed in this manner. They are built entirely of wood and of rectangular shape, from 30 to 40 feet wide and from 80 to 100 feet long. The sides of the bath are about 8 feet high, composed of small dressing rooms with a narrow platform running around the water of the bath in front of the dressing rooms. Below the dressing compartments there is a certain amount of boards and planking to render buoyancy, and projecting down below the water to a distance of 6 or 8 feet are planks and slats which also increase the buoyancy and keep out floating débris.

Each bath consists of only one swimming compartment and the bottom is floored over so that the water is not over a depth of 4 or 6 feet, to prevent drowning accidents, and there is no roof over the swimming pool.

The majority of days are reserved for male, and other days for female bathers. In the Manhattan baths the same number of days were reserved for female as for male bathers during the season of 1910. During the summer the baths are in great demand and only as many bathers are allowed at a time as can be accommodated in the bath. It is a common sight on a warm summer day to see hundreds of boys standing ready to make use of the bath, being held back only by a policeman; and after a definite time of twenty or thirty minutes the boys within the bath have to be driven out and driven away from the neighborhood of the bath by the bath attendants and policeman, only to be seen slinking back in twos and threes to await their turn again to make use of the bath.

The bath is undoubtedly enjoyable to these boys and young men, if one can judge by their antics. Good swimming is common, and on the first plunge the mouths of many are filled with water only to be spurted out again like so many young whales. Diving, though prohibited, is also frequent. Boys below puberty go into the baths nude, older boys and men must wear trunks. Women wear bathing suits.

The floating baths were situated, with but one exception, either adjacent to Manhattan or in the East River, moored to docks made available for this purpose.

The baths have been made use of during a season extending from about July 1 to the first week in October. In 1908, during a season of 102 days, there were 1,479,025 male baths and 934,936 female baths, a total of 2,413,961 baths, an average of 1,067 baths daily. How many different individual bathers use the baths during a season is purely conjectural.

During the season of 1909 there were 1,392,310 male and 930,760 female baths, a total of 2,323,070 baths. Besides these free public baths there were a number of private floating baths and bathing beaches open to the general public during the summer of 1909. (See Table I.)

*Part of report made for the Metropolitan Sewerage Commission, 1910.

TABLE I.—TOTAL NUMBER OF BATHS TAKEN IN FLOATING AND INTERIOR BATHS DURING THE YEARS 1909 AND 1910, IN MANHATTAN, BROOKLYN AND THE BRONX.

	1909.	1910
Manhattan:		
Floating baths	2,323,070	2,410,295
Interior baths	5,271,422	4,916,298
Brooklyn:		
Floating baths	644,725	778,805
Interior baths	2,405,960	2,770,985
The Bronx:		
Floating baths	.....*	72,047**
Interior baths	229,918	315,476

*No floating bath during 1909.
**Floating bath only from July 28 to September 30.

Inland Bathing Establishments.—In addition to the floating bathing establishments there are eleven so-called interior bathhouses in the Borough of Manhattan. Of these the Cherry and Oliver street bath was opened November 15 and the Rutgers place bath on December 28, 1909. In East Fifty-fourth street a bathing establishment was opened February 17, 1911. There is one interior bathing establishment in the Borough of The Bronx and there are eight in the Borough of Brooklyn.

These interior bathing establishments have been erected to provide opportunities for free bathing. They are arranged with tubs and showers for both men and women. Towels and soap are not furnished because the loss of towels was found, upon experiment, to be very great, and there was a constant danger of infection from their use; soap was found to be wastefully used when given free.

The interior public bathhouses are of much more value to the public than the floating bathing establishments because, for one reason, they are open daily throughout the year for men, women, and children. They are both cleansing and wholesome and there is no danger of the transmission of disease.

The newer interior baths have been built in localities where the population is densest and in neighborhoods where the floating bathing establishments would necessarily have to be placed in harbor waters more or less intensely polluted.

TABLE II.—INTERIOR BATHS.—MANHATTAN. BUREAU OF BATHS AND PUBLIC COMFORTS.

Location.	Men.		Women	
	Tubs.	Showers	Tubs.	Showers
324 Rivington Street	5	69	5	22
347 West 41st Street	4	73	6	29

202 West 60th Street (Also swimming pool 35x50 ft.)	..	49	1	20
Avenue A (between 23d and 24th Streets) (Also swimming pool 40x70 ft.)	2	76	4	74
83-85 Carmine Street (Also gymnasium and roof garden)	2	90	5	35

These baths are open daily throughout the year from 6 A.M. to 9 P.M.

In the year 1908 there were 7,907,230 baths taken in the public interior bathhouses in the City of New York. Of this number 5,271,422 were taken in Manhattan, 2,405,890 in Brooklyn, and 239,918 in The Bronx. In the latter borough the figures

include baths taken from May 17 only, the date of opening, to December 11, 1909.

In the same year there were also taken, in private interior bathing establishments, 64,502 baths at the Riverside House, 55,367 at Center Market place, 201,290 at the Milbank Memorial Bath, and 37,012 at the Demilt Dispensary. (See Table II.)

II.—Park Department.

	Showers.	
	Men.	Women.
Seward Park	30	21
DeWitt Clinton	21	21
Thomas Jefferson	21	21

Open from 6 A.M. to 10 P.M. Children and adults on alternate days.

III.—Board of Education.

The following schools are provided with baths: 1, 8, 21, 34, 38, 51, 147, 173, 188, and High School of Commerce (plunge).
These are open to boys and girls during the summer.
Opened in 1909 and 1910.
Cherry Street, corner Oliver, November 15, 1909.
Rutgers Place, near East River, December 28, 1909.
East 54th Street, near First Avenue, 1910.

Brooklyn.—I.—Bureau of Baths and Public Comforts.

Location.	Men.		Women.	
	Tubs.	Showers	Tubs.	Showers

Floating baths	2,413,961	2,967,795	3,261,147
Interior baths	.....	7,907,300	8,002,759

Location of the Floating Bathing Establishments.—To secure a site for a free floating bathing establishment application is made by the Department of Public Works to the Department of Docks and Ferries, which designates the docks available for the purpose. The site is not finally decided upon, however, until after an inspection is made by the Department of Health which has authority to refuse permits to the site.

"Regulating the Sanitary Condition of Bathing Establishments and the Preservation of Life at Bathing Places. It shall be unlawful for any person to maintain, either as owner or lessee, any bathing establishment of any kind, in this State, for the accommodation of persons, for pay, or any consideration, at a point less than five hundred feet from any sewer connection emptying therein or thereat, so as to pollute, in any way, the waters used by those using or hiring bathing houses at such bathing establishments; it shall be the duty of such owner or lessee to provide separate toilet rooms, with waterclosets properly provided with sanitary plumbing, constructed in a manner approved by the local board of health and in such a way as not to contaminate the waters used by the bathers; it shall be the duty of such owner or lessee to thoroughly wash and disinfect or cause to be thoroughly washed and disinfected, in a manner approved by the local board of health, all bathing suits that have been hired or used, before rehiring or permitting the use of the same again."*

This law, although prohibiting the establishment of a floating bath or bathing place, does not apply to free floating baths or free bathing beaches. It is also qualified by the statement "so as not to contaminate the waters used by the bathers."

These regulations show that legislative precautions were taken, though whether the law was intended to overlook free floating bathing establishments and bathing beaches is not known.

The outer sides of the bathing establishments, which project as a rule from 6 to 8 feet below water, are usually made of slats several inches apart. These have been found inadequate to keep out floating débris and the larger particles of sewage with which the harbor waters abound. In some of the establishments boards have been nailed close together (in one sand bags have been piled up) to keep out the larger particles, and in many a small net on a pole, similar to a crab net, is kept to remove masses of feces when they become too numerous.

The sewer outlets of Manhattan are so near together that it hardly seems possible to pick out locations for floating bathing establishments free from danger of intense sewage contamination.

The free floating bathing establishments were moored during the summer of 1909 in the situations given in Table III.

Direct Contamination from Sewers. Object of Dye Experiments.—A number of experiments were made in order to learn whether or not water polluted with sewage could be traced directly from a sewer outlet to the waters within the baths. Thirty-two different experiments were made upon fourteen different baths. The dye was introduced into the water at a sewer outlet when the current was flowing in the direction of the bath, and the dye was then found coloring the water inside of six baths within a few minutes, and in two other baths the dye was seen staining the water around the bath.

The experiments were all made by employees of the commission. Uranine and special scarlet were the dyes used. The dye was introduced into the sewer near its outlet or into the water just at the outlet. The experiments were all made when the tidal conditions were such that the direction of the current would tend to carry the dye from the sewer's mouth toward the bath. The general conditions were noted, such as the direction of the tide, the time, the dye used, and the length of time

*Chapter 454, Laws of New York, 1905 (extract).

taken for the dye to flow from sewer outlet to the bath.

TABLE III.—SHOWING LOCATION OF FLOATING BATHING ESTABLISHMENTS IN RELATION TO SEWER OUTLETS

Location of Bathing Establishment.	Nearest Sewer Outlet.	Size of Sewer.	Distance of Sewer from Bathing Establishment
East River:			
Rutgers St.	Jefferson St	5′	662.5 ft. north
	Rutgers St	15″	225 ft. north
	Market St.	4′ 3″	1,062.4 ft. south
	Oliver St.	5′ 8″	1,875 ft. south

	Greenpoint Ave.	2′	517 ft. north
Dock St	Fulton St	6′	882 ft. southwest
	Main St.	3′	488 ft. west

The following description shows the nature of one of the experiments:

July 7, 1909. Weather fair, tidal current strong upstream, wind southwest. Low water Governors Island 7:58 A.M. Current flood. 10:45 A.M., put one pound special scarlet in outlet of sewer on Eightieth street pier. Color flowed upstream at rate of about half mile per hour. 11 A.M., color reached bathhouse and surrounded it. Observer went into bathhouse. 11:01. A.M., color very strongly visible in swimming pool. Boys bathing noticed it. 11:05 A.M., a policeman and bathhouse keeper went on roof of bathhouse to see where color in the swimming pool was coming from. 11:12 A.M., observer left vicinity.

Addenda. Swimming pool on inspection before arrival of color showed bits of floating sewage, but no large lumps of feces visible.

This bath is 764 feet from the sewer outlet. The color reached the bath from the sewer outlet in sixteen minutes. This shows that sewage discharged from the West Eightieth street sewer during the ebb current flowing landward will pollute the West Eighty-third street bath during practically the entire duration of this current.

Thirty-one other experiments of a similar nature were made. (See Table IV.)

In the East River ten experiments were made upon the following five baths: Pier 33, two experiments; Egan's private bath, two experiments; Corlears street bath, one experiment; East Fifth street bath, three experiments; East Ninety-sixth street bath, two experiments.

At Pier 33 bath dye introduced into Rutgers street sewer, 225 feet away, was readily followed with the naked eye to within the bath.

At East Ninety-sixth street bath dye introduced into East Ninety-fifth street sewer, 323 feet away, readily found within bath.

At East Fifth street bath dye introduced into mouth of East Fourteenth street sewer, over 1,500 feet away, soon surrounded the bathhouse, but dye was not seen within the bath.

At the Corlears Park Baths in three experiments the dye did not enter or even surround the baths.

In the Hudson River thirteen experiments were made upon six different baths. Two experiments at the Battery Baths, four at West Fifty-first street, three at West Eighty-third street, one each at West Ninety-seventh street, West One Hundred and Thirty-seventh, and West One Hundred and Fifty-fifth streets, the latter a private bath. In three of these baths, West Fifty-first, West Eighty-third, and West One Hundred and Fifty-fifth street baths, dye was found to enter when introduced into an adjacent sewer.

Dye introduced into the West Fiftieth street sewer was readily followed to within the Fifty-first street bath, 252 feet away.

Dye introduced into the West Eightieth street sewer was readily followed to within the West Eighty-third street bath, 764 feet distant, and stained Mahon's beach 970 feet away.

Dye introduced into West One Hundred and Fifty-eighth street sewer readily stained water of West One Hundred and Fifty-fifth street private bath and West One Hundred and Fifty-fifth street bathing beach, both over 600 feet away.

In Brooklyn nine experiments were made upon four different baths, Dock street, Fifty-eighth street, Noble street, First street. The First street bath had been removed when the experiment was made, but dye was followed from Metropolitan avenue sewer to previous site of bath.

Dye entered the Dock street bath when introduced into either the Main or Fulton street sewer, 882 and 488 feet distant.

At Fifty-eighth street dye did not enter bath, but flowed about it when introduced into Sixty-fourth street sewer.

Dye introduced into Seventy-ninth street sewer floated past water in front of private bathing beach at Eighty-fourth street.

In these dye experiments it must be remembered that the dye was introduced into the water at only one instant and into one sewer at a time, while the discharge from the sewer is nearly continuous. It is further evident from the experiments that, although dye introduced into the sewer did not reach the bath, yet if repeated a few minutes later or at the same time the next day it would reach the bath. In one instance (the East Fifth street bath) dye introduced into the East Third street sewer, two blocks away, did not enter or surround the bath, but dye from the Fourteenth street sewer nine blocks away did very promptly surround the bath. So it is very likely that with each bath,

*Color about bath, but did not enter it.
†Bath removed. Water at site of bath contained fecal matter, sewage and experimental dye.

excepting possibly the Battery Baths, if the experiments were continued, dye could be followed from sewer outlets to the baths.

Inspection of Baths.—A few inspections were made of the floating baths at the time of making the dye experiments. Floating fecal matter was seen in the Dock street bath, Pier 33 East River bath, Egan's bath, Corlears street free floating bath, East Ninety-sixth street bath. Floating particles of sewage were seen in these baths and also at West Fifty-first street and West Eighty-third street baths. Other inspections have shown frequently the presence of floating sewage in many of the baths.

The Quality of the Water.—It has been shown by dye experiments that the water in the floating baths is contaminated by liquid sewage from adjacent sewers. It has also been shown that the water in the baths contains floating sewage particles and fecal matter. Irrespective of and more important than contamination from an adjacent sewer is the general quality of the water used in the baths.

Numerous examinations of the oxygen content of the various parts of the harbor showed that in many places the oxygen was diminished, and examinations were made also to determine the presence of colon bacilli, which were always found to be present in amounts of water as small as 0.01 to 0.001 c.c.

Slowness of Currents in Carrying Objects to Sea.—The tide rises and falls on an average of 4 feet, much less than in many tidal harbors. With a long harbor and this comparatively small rise and fall of the tide, the currents flow comparatively slowly. So that with each change of the direction of the tide the harbor is not completely flushed.

This was definitely proven by the float observations made by the Commission, which showed that objects set afloat in the Hudson or East Rivers take several tides before they finally pass out through the Narrows toward the Lower Bay. This means that sewage discharged from a sewer outlet on Manhattan, even with a current flowing south, is not carried out to sea, but oscillates to and fro for some time before it is finally digested.

Tendency of Sewage to Collect Along the Shores.—It has also been observed that visible particles of sewage and fecal material have a tendency to collect in fields along the shores, apparently being drifted to the shore by the currents, which keep the center of the rivers fairly clear, but the waters along the shores filled with floating material. Naturally these masses of floating sewage material are seen in greater quantities near the sewer outlets and in places which drain the larger areas of population. This is especially true of the shore line of Manhattan and more marked in the East River than in the Hudson. Unfortunately the demand for floating baths is greater in the more densely populated areas, exactly where the largest amounts of sewage material are poured into the rivers.*

Dangers of Bathing in These Waters.—The urine and feces discharged not only from the healthy population, but also from a large number of patients suffering from specific infectious diseases, go constantly into the sewers without disinfection, either from ignorance of the presence of the disease or from inability or unwillingness to disinfect these discharges.

It is known that typhoid fever is commonly a water-borne disease. The discharges from one patient may pollute the entire water supply of a large city sufficiently to cause a serious epidemic. The other infectious diseases, such as pneumonia, meningitis, tuberculosis, and diphtheria, may be water-borne, though other ways of infection seem more likely. It has been frequently shown that one glass of water polluted with typhoid bacilli may cause typhoid fever.

The waters of the harbor, contaminated constantly by pouring sewage into them, must contain typhoid bacilli. It has been shown that these bacilli may live for months virulent in water, but for shorter periods of time in sewage.

While bathing in the floating baths and in other contaminated waters it has been shown that water is taken into the mouth. Anyone who has bathed in this manner knows that water is not infrequently swallowed. The casual bather, therefore, runs a risk of receiving typhoid bacilli into his alimentary canal by bathing and swimming, and the risk of the constant bather is increased.

Conclusions.—I. There are a large number of people in the metropolitan district constantly ill of specific diseases. The discharges of many of these patients containing specific disease-causing bacteria are emptied undisinfected into the sewage. Some of these bacteria, notably the typhoid bacillus, may live for days in sewage and sea water. Other bacteria causing specific diseases may live in sewage and sea water, though less is known about them, and this seems only possible, rather than probable.

II. There is danger in bathing in the harbor waters. The floating baths have but little cleansing value and the water is unwholesome for bathing purposes. They may be refreshing to some and give pleasure to thousands, some of whom learn to swim.

III. Floating particles of sewage enter many of the baths even though they are situated 500 feet or more from the sewer outlet.

IV. The quality of the water adjacent to the shores of Manhattan and Brooklyn in the East and Hudson Rivers and the Harlem River is such that it is unsuitable for bathing purposes even though it were possible for the baths to be so situated and protected that floating particles of sewage did not enter the floating baths. This water is constantly diminished in oxygen, contains large numbers of acteria, among which are colon bacilli in 0.01 to 0.001 of a cubic centimeter of water.

V. While bathing in these waters it is hardly possible to prevent water from entering the mouth and nasal passages and also the mucous membrane of the eye, and bathing in such water is a constant source of infection.

*The Department of Health in 1910 refused to approve the locations of any of the free floating baths of Manhattan, but said that they were as good as could be selected on our water front.

"CARRIERS" IN RELATION TO THE SPREAD OF DIPHTHERIA.*

By EBEN C. HILL, M.D.,
U. S. ARMY.

This article is presented in order to invite attention to the most recent views regarding the epidemiology of diphtheria as taught by Chapin; to record a recent epidemic of this disease in which his theories were tested, and to show the results that may reasonably be expected from the rational use of antitoxin in treating diphtheria.

"From time immemorial miasms, malarias, vapors, and emanations, gaseous or otherwise, have

*Published with the authority of the Surgeon General, United States Army.

been believed to be the frequent cause of disease. These miasms were thought to arise from stagnant marshes, decaying vegetation, putrid animal matter, and indeed filth of every kind. This belief in the extracorporal origin of disease reached its widest acceptance about the middle of the nineteenth century. The rise of the germ theory greatly strengthened it. It now appears that the growth of disease germs outside of the body is not frequent enough to be an important factor in the causation of disease, but their growth in the body without causing sickness, their latency as it were, often for many months, is a factor of very great significance. We know now that direct contact with the sick, or with healthy carriers of disease germs, is an exceedingly frequent mode of transmission, and that infection by means of the air, or from infected articles, is not nearly as common as was formerly believed."

Thus Chapin, in his very instructive and scholarly summation of a vast amount of evidence as to the sources and modes of infection, prepares the reader for some rather startling theories. "Diphtheria was not so long ago believed to be a filth disease, that is, its germs were supposed to have a habitat outside of the body in various forms of dirt." After citing among other authorities Houston, Nuttall, Graham-Smith, and Kersten, he states in regard to diphtheria that except in fairly fresh milk at room temperature it is unlikely that the bacilli of diphtheria multiply outside of the body and that so far as experimental evidence is concerned there is no warrant for assuming such a source for this disease. It is true, he says, that these bacteria may be conceived as growing outside of the body under natural conditions, but such growth, if it ever occurs, must be rare.

He then shows by statistics and "pin maps" that if this disease did arise from garbage, privy vaults, sink drains, soil, clothing, or other fomites outbreaks would not occur in one section of a city and die out only to occur again in an entirely different part of the town. The time-honored disinfection of houses in diphtheria; our pet theories as to air infection, bad drainage, used toys, and various fomites which so conveniently if not scientifically explained the spread of disease; the necessity for the protective gown; all of these seem to lose their firm traditional foothold as we study the evidence presented, and our teachings of student days must be materially readjusted if we accept his conclusions. At first, so radical do these views seem, that the physician is not only incredulous but likewise unwilling to be convinced, and immediately attacks the foundations on which Chapin bases these theories as to the transmission of disease. Unfortunately for the peace of mind of the physician, however, he must in the end grant that the mass of evidence so clearly presented is at least very suggestive if not absolutely conclusive.

Were it possible or permissible, I would like to abstract his book, but since the book is in itself an abstract of evidence, such a proceeding is out of the question. Just a few of his observations are herein mentioned in order to give a suggestion of the line of reasoning that he follows. By "pin maps," by reports of investigations of epidemics of diphtheria, and by bacteriological evidence he shows that too much stress has been laid on inanimate objects as sources of infection. He compares the present attitude toward fomites in diphtheria and allied diseases to the former supposed proof that yellow fever was likewise spread by bedding or clothing of patients who were or had been suffering from this disease. As he points out, the proof that yellow fever was so disseminated was much more conclusive than the facts and theories which at present warrant the belief that diphtheria is most frequently transmitted by fomites. Concluding from epidemiological and bacteriological evidence that fomites play but a minor part if any in the spread of diphtheria, no disinfection of houses was carried out in Providence, R. I., from 1905 to 1909. Naturally it would be expected, if the old theories are to be relied on, that such a practice would result in a great increase in the number of infections. Especially marked would this be in Providence, where to a great extent many families occupy the same house. Yet the following tables do not indicate any such remarkable increase:

TABLE SHOWING THE NUMBER OF OCCURRENCES AFTER DISINFECTION AND WHEN NO DISINFECTION WAS MADE, THE NUMBER OF INFECTED FAMILIES, AND THE RATIO BETWEEN THE TWO.

	Year.	Infected Families.	Recurrences.	Ratio.
Disinfection till February, 1905.	1902	358	6	1.67
	1903	453	7	1.54
	1904	559	10	1.78
	1905	87	2	2.30
Total.....	. .	1457	25	1.71
No disinfection after February, 1905.	1905	258	4	1.55
	1906	259	4	1.55
	1907	343	7	2.04
	1908	647	17	2.34
	1909	472	10	2.12
Total.... ..	...	2019	42	2 08

In studying these statistics it is of interest to note that in Baltimore, where terminal disinfection is practised in an unusually thorough manner, and is in a large majority of instances tested for its efficiency, recurrences in diphtheria occur in 1.89 per cent. of the cases.

Again we find that in Providence during the past six years no clothing sent to the laundries from houses containing diphtheria patients was disinfected yet there has been no increase in the disease among the laundry workers.

The conclusions that Chapin reaches in his studies are: That mild and unrecognized cases of infectious diseases are often extremely common. In many instances they may be more numerous than the recognized cases. That disease-producing microorganisms frequently persist in the body without causing symptoms. That sometimes the germs remain only a few weeks or months after convalescence, and sometimes they may persist for years, perhaps for life; sometimes these carriers give no history of having been sick. That, while the bacteria found in carriers are sometimes lacking in virulence, many times they show the highest degree of virulence. That there is ample epidemiological evidence to show that healthy carriers as well as mild unrecognized cases are the source of well-marked outbreaks. That any scheme of prevention which fails to take into account carriers and missed cases is doomed to partial and perhaps complete failure. That observations made in Providence, R. I., a city of over 224,000 inhabitants, indicate that fomites infection is of no practical importance in the diffusion of diphtheria. That experiments show that the bacillus of diphtheria dies off very quickly in unsterilized soils of various kinds; and

that except in fairly fresh milk at room temperature it is unlikely that the bacilli of diphtheria multiply outside of the body. And, finally, that evidence has been rapidly accumulating that tends to prove conclusively that fomites infection is of very much less importance than was formerly believed.

A Recent Epidemic at Madison Barracks, N. Y.—In a recent epidemic of diphtheria at Madison Barracks, N. Y., Major Frederick P. Reynolds, M. C., U. S. Army, was temporarily at the post and Captain Frank W. Weed, M. C., U. S. Army, arrived shortly after the outbreak of the disease. These physicians had very recently reviewed Chapin's new book on epidemiology and in outlining the plans for investigating the origin and spread of the disease they laid less stress on the time-honored theories of fomites and directed attention to the possibility of carriers, missed cases, or an infected milk supply. The possibility of fomites infection was thoroughly investigated, but all evidence tended to sustain Chapin's theories as to other means of infection.

In order to give a clear, concise account of this epidemic, a chart of the relative positions of the officers' quarters is presented in order to show: (1) the houses in which diphtheria occurred, (2) the earliest probable date of infection, (3) the date when the clinical and bacteriological examinations proved the presence of diphtheria, (4) the date of complete recovery of the last case in each house, (5) the number of children and adults belonging to the families, and (6) the initial of the milk dealer supplying these families.

No mention is made concerning the water supply or the dealers who delivered provisions because after a careful search it was shown that all of these families received these supplies from the same source.

Source of the Epidemic.—On December 22, 1910, one of the practising physicians of Sackett Harbor, N. Y., asked me to see a certain Mr. G. D. This man had been suffering for nearly three weeks from a profuse, purulent nasal discharge together with more recently developing symptoms of toxemia. These latter symptoms were especially noticeable in a weakened heart action. During the three weeks previous to my examining him, he had been continuing his daily duties as helper and assistant in the principal meat market of Sackett Harbor. From this store most of the families of the garrison purchased provisions. Smears made from this man's throat and nose showed great numbers of diphtheria bacilli in the specimens taken from the nasal secretion. Dr. Meader, bacteriologist of Watertown, N. Y., and later the New York Health Board verified these findings. The man was immediately quarantined.

Sackett Harbor is a small village located about a quarter of a mile from Madison Barracks. The post families traded daily with the store in which this diphtheria carrier was an assistant. Mrs. N., mother of Willoughby N., recalls having been to this shop with her young son on many occasions before Mr. D. was quarantined. She also remembers having had rather protracted conversations with this man during the time that he was suffering from nasal diphtheria. Willoughby N. was the first of the post children infected with diphtheria. On December 24, 1910, his parents noticed that he had a slight nasal discharge and a croupy cough. So insidious was the onset and so closely did the symptoms resemble a simple catarrhal condition of the air passages that the attending physician very naturally diagnosed the condition as an ordinary "cold," gave a few remedies and advised the family to keep the child out of doors as much as possible. As a consequence, he came in almost daily contact with the other children of the post. (See chart for location of this case.) From December 24 until the time that the disease was correctly diagnosed as diphtheria the nasal discharge and cough increased in amount and severity. His was the second very infectious case in the progress of the epidemic. Captain and Mrs. N., his parents, were in constant attendance upon him, and it appears most probable that their later infection was acquired from their own child. Lt. A. was a frequent visitor at this captain's house and also as a lieutenant in his company they were brought into daily contact. Hence it is justifiable to trace the infection of this lieutenant to some member of the N. family.

* indicates first diagnosed case. M.,D.,R., initials of milk men delivering milk at houses. This chart was made at the suggestion of Major Reynolds, M.C. and Captain Weed, M.C. in order to indicate the spread of the epidemic.

Chart of the Epidemic.

Lt. Bn. and Lt. A. live in bachelor quarters and dine together. The P. children were quite friendly with Willoughby N., and saw him frequently during his infectious stage. The Bt., Mt., and Pt. children gave histories of a similarly close contact with Willoughby N.

Lt. and Mrs. Mn. are relatives of Captain and Mrs. N., and they dined and visited together frequently. The probable dates of infection in these various cases have been already noted in the chart.

The Discovery of the Presence of Diphtheria on the Post.—The first diagnosis of diphtheria was made on January 25, 1911, when I was called in to examine Willoughby N. This boy's father, Captain N., had come to the post hospital on the

morning of the 25th because of partial deafness and a slightly irritated throat. Upon examination a membrane was noted in the pharynx from which smears were made. An examination made later in the day after seeing Willoughby N. showed diphtheria bacilli. Because of this apparent membrane and the presence of a serious case of diphtheria in Sackett Harbor, I examined Willoughby N. very carefully. I found the boy irritable, restless, and anemic. His face was very pale, the mucous membranes were blanched, the tongue coated, the breath offensive, and there was a catarrhal nasal discharge. He had a croupy cough which, according to the parents, had been increasing in frequency since December. Cultures from the throat and nose showed diphtheria organisms.

As soon as this diagnosis had been assured, a careful inquiry was made in Sackett Harbor to locate any similar cases of diphtheria, but the records of the local health board showed only the one case previously referred to. There was no other reported case during the past nine months. The school principal reported cases of "sore throat," but stated that none of these children had, to his knowledge, suffered from diphtheria.

The barracks, in which about five hundred soldiers are quartered, is located about a quarter of a mile from the officers' quarters. Smears and cultures were taken from all enlisted men showing catarrhal inflammations of the respiratory tract. Also the children of the officers' families and others residing with them were similarly examined. No diphtheria was at any time found among the soldiers, but six cases were immediately detected in the officers' families. Several children presented symptoms of a catarrhal rhinitis or laryngitis, but three successive cultures failed to reveal the presence of diphtheria organisms. On January 26 and 27 smears were made from the throats and nostrils of many more of the officers and members of their families, and several more cases of the disease were discovered. A day or so later Captain Weed arrived at the post and immediately proceeded to investigate the origin of the disease. He made three or four hundred cultures from the throats and nostrils of all officers, members of their families, and servants. This examination showed positive cultures from the throats and nostrils of thirteen of the inmates of the quarters in which there were one or more recognized diphtheria patients. These persons had been in close contact as nurses or attendants upon the diphtheria patients but none of them subsequently developed any symptoms of the disease. This may have been due to the immunizing dose of 1,000 units of antitoxin which was given to all exposed persons. These persons were simply temporary carriers of the disease. A similar cultural examination carried out among the tradespeople of Sackett Harbor developed the fact that nine of them had diphtheria bacilli in their throats, and one had these bacilli in his nose and throat.

The presence in the community of these unrecognized carriers is of particular significance when we consider that the health records showed only one case of diphtheria during the past nine months. This one case was Mr. G. D., to whom reference has already been made. Jacobi as early as 1884 recognized the danger of these carriers and mild atypical cases. In commenting on the atypical types of the disease his words are well worth careful consideration. "The symptoms are often but few. A little muscular pain and difficult deglutition are perhaps all that is complained of. Women will quietly bear it; men will go about their business. . . . . There is as much diphtheria out of bed as in bed; nearly as much out of doors as indoors. Many a mild case is walking the streets for weeks without caring or thinking that some of his victims have been wept over before he was quite well himself. . . . . Diphtheria is contagious. Severe forms may beget severe or mild forms. Mild cases may beget mild or severe cases."

There was no evidence to connect the origin of this epidemic with a contaminated milk supply. A milk epidemic is determined to be such from the presence of an excessive number of cases on a particular milk route. Such was not the condition as found at the Barracks. Also Chapin maintains that it is not justifiable to presuppose a contaminated milk supply even if there are several cases on a certain route until all other evidence as to the origin of the disease has been carefully considered.

Careful search revealed no proof of fomites having played any part in the spread of the disease. All proof seems to conclusively show that carriers and missed cases were responsible for the epidemic.

Brief Histories of the Cases in Order of Occurrence.—In this epidemic Mr. G. D., to whom the epidemic was traced, died after a lingering illness. Aside from the fact that he received only 6,000 units of antitoxin after the disease was diagnosed as diphtheria, I have no record of the case and saw the man only once.

Case I.—Willoughby N. Age 5 years, son of Captain N. This child, according to the statements of his parents, had been suffereing from a catarrhal discharge from the nose and a persistent cough since December 24, 1910. From this date until January 25, 1911, when I first saw the child, there had been increasing weakness and irritability.

On January 25, 1911, when I was called to see the child for the first time, I found that he was irritable, restless, and anemic. His face was very pale, the mucous membranes were blanched, the tongue coated, the breath offensive, and a catarrhal discharge was issuing from his nose. There was a croupy cough which occurred every few minutes, and this, according to the statement of the family, had been increasing in frequency since December 24, 1910. The throat was red and inflamed, but not markedly swollen. The cervical glands, posteriorly, were enlarged and felt like small hazel nuts. The nostrils were reddened and there was a little discoloration of blood on the swab used in making a smear from the nostrils. I was unable to see clearly into the larynx and hence cannot say whether there was a membrane present in that location. The lungs were clear but inspiration and expiration seemed a little prolonged, and over the trachea there was the suggestion of an impediment which seemed to me to point to the possible presence of a membrane. The heart was normal in rhythm and no murmurs were heard. Cultures from the nose and throat were positive for diphtheria bacilli. The pulse was 156. Temperature (rectal) was 103.5°; respiration 36. The child was immediately put to bed and though he had been exceedingly restless and irritable while up and dressed, and had protested against being put to bed, he shortly became quiet and remained quietly in bed from that time on. Soon after being put to bed he vomited.

January 26, 1911: 11:30 A.M., pulse, 154; temperature, 103°; respiration, 34; 10,000 units of antitoxin were given. Practically no improvement

noticed except that the cough was less severe. The patient refused food. 1:00 P.M., pulse, 145°; temperature, 102.2°; 4:30 P.M., pulse, 147; temperature, 103°; the child is perspiring freely; 6:00 P.M., pulse, 138; temperature, 102.4°; respiration, 36; 7:00 P.M., pulse, 144; temperature, 103.2°; respiration, 37; 5,000 units antitoxin given.

January 27, 1911: 9:00 A.M., pulse, 142; temperature, 103°; 5,000 units antitoxin given; 3:00 P.M., pulse, 152; temperature, 102.8°; 6:00 P.M., pulse, 135; temperature, 102.4°; respiration, 36; 5,000 units antitoxin given. The cough was loosened and is less freqquent. The child has slept most of the day. The appetite has returned and there has been no vomiting.

January 28, 1911: 8:30 A.M., pulse, 130; temperature, 101.5°; respiration, 32; 8:00 P.M., pulse, 118; temperature, 101.3°. The child seems much better. His appetite is good and he is cheerful and not at all irritable. Only liquid food in small quantities and at frequent intervals has been given, and the patient has not been allowed to exert himself.

January 29, 1911: 8:00 A.M., pulse, 114; temperature, 100.8°; respiration, 28; 2:00 P.M., pulse, 127; temperature, 101.6°; respiration, 32; 8,000 units antitoxin given. There is a marked return of the restlessness and irritability. 8:00 P.M., pulse, 110; temperature, 99.8°; respiration, 24; the patient is drowsy.

January 30, 1911: 8:00 A.M., pulse, 104; temperature, 99.8°; respiration, 22; 8:00 P.M., pulse, 100; temperature, 100°; respiration, 23; the child has passed a comfortable day, is cheerful and has a good appetite.

January 31, 1911: 9:00 A.M., pulse, 102; temperature, 99.8°; respiration, 21; 8:00 P.M., pulse, 105; temperature, 100°; respiration, 22; the child seems to be regaining strength. He is kept on his back in bed and is given only liquid nourishment. No stimulation has been needed. The heart is regular, strong in action, and no murmur or enlargement is detected.

February 1, 1911: 9:00 A.M., pulse, 100; temperature, 99.8°; respiration, 20; 4:00 P.M., pulse, 90; temperature, 97.4°; respiration, 28. Up to this time there had been apparently the usual trend of the disease. The pulse was of good quality and regular. The appetite had been excellent. There had been no nausea or vomiting. The cough had entirely disappeared and there had been no discharge from the nose for many days. The child's voice, which at the beginning of the attack was hoarse, had cleared.

At 6:30 P.M. I was hastily summoned and found the child in a very dangerous and seemingly fatal collapse. The pupils were dilated, the eyeballs divergent, perspiration covered the entire body, and the skin was cold and clammy. The family stated that several sudden attacks of vomiting had occurred. The child was comatose. The pulse was not perceptible at the wrist. Examination with the stethoscope revealed greatly irregular and weakened cardiac action. There would be several beats and then a lapse of a quarter of a minute. The rate varied from 20 to 30 to the minute. Five c.c. of brandy were given hypodermically, with no response on the part of the heart. At intervals of about five minutes brandy, strychnine, and digitalin were given hypodermically until 30 c.c. of brandy, 1/15th grain of strychnine, and 1/25th grain of digitalin had been administered. The pulse gradually became more rapid, but remained irregular and weak.

It was immediately apparent that this was a toxic neuritis of the pneumogastric nerve, so graphically described by Holt, as follows: "This usually follows severe types of infection, and is seen not only in cases in which no antitoxin is given, but also when it is administered late or in small doses. In such circumstances the early toxemia may be neutralized and the local disease in the larynx and trachea controlled; yet so suspectible are the nervous tissues to the action of the diphtheria toxin, that injury sufficient ultimately to produce death may still have been done. This is most frequently through the action of the toxin upon the pneumogastric nerves. Pneumogastric paralysis may come on at any time in the course of the disease, but seldom earlier than the end of the second week. By this time the throat has usually cleared off entirely, and the patient is considered convalescent. The physician has ceased his frequent visits, and looks in only once a day to satisfy himself that all is going well. The symptoms relate to the stomach, heart, and respiration. Usually the first thing to attract notice is that the patient refuses food and vomits occasionally, afterwards persistently, without apparent cause. If the pulse is carefully observed it is found to be much slower than previously, being only 80 or 90 when it was formerly 120 or more. It is also weaker, compressible, and often somewhat irregular. The face is pale, often somewhat cyanotic, and moderate dyspnea may be noticed. There are frequent attacks of severe abdominal pain which comes in paroxysms, and is usually referred to the epigastrium. These symptoms in most cases gradually increase in severity for two or three days, but sometimes develop with such intensity that death occurs within twelve or twenty-four hours. The later symptoms are a continuance of the abdominal pain and vomiting; there is a feeling of great precordial oppression and distress accompanied by dyspnea; the respiration is shallow and often rapid; the face is either pale or cyanotic; the extremities cold; the pulse slow, irregular, and intermittent, becoming rapid on the slightest exertion. The heart sounds are weak, the muscular quality is absent, and the rhythm much disturbed. There may be no murmurs. There is great restlessness, but the mind is entirely clear. Death usually results from syncope, which may come quite suddenly, often from so slight exertion as turning over in bed or attempting to take food."

"Not all cases are so severe. In the milder forms of the condition there are some palpitation, an irregular pulse, slight dyspnea, and occasional syncopal attacks, but of no great severity. Such symptoms may come and go for several days and then disappear; but more frequently they prove to be the beginning of the more serious form of the complications. The time of the occurrence of the pneumogastric paralysis varies considerably. It may be as late as the third or fourth week. The late cases are generally associated with some other form of post-diphtheric paralysis."

Major Frederick P. Reynolds, Medical Corps, spent that night with the child and administered stimulants as needed.

February 2, 1911: 8:00 A.M., pulse, 68; temperature, 98.2° (rectal); respiration, 28. Pulse very irregular and weak. A paralysis of the left arm, forearm, and hand was noticed at this time. This persisted for nearly a week. Hypodermics of strychnine, digitalin, and whiskey were given when indicated, and for two weeks there were periods when these stimulants were needed every

three or four hours. The temperature at times fell to 97.2° (rectal), and the pulse rate to 54, even with stimulation, Tincture of digitalis and tincture of strophanthus were also given regularly. There were three attacks of a similar but less intense nature to that which occurred on February 1.

The pulse was taken every fifteen minutes day and night for three weeks. The sudden and very marked changes in rhythm and rate rendered this absolutely necessary. When the child fell asleep there would be a sudden drop from 90 or 100 to 45 or 50, with a decided weakening and irregularity. At certain times a divergent strabismus appeared, together with shallow breathing and cyanosis. At the end of seven days the paralysis of the left arm and hand disappeared, and after a month the child was well enough to be allowed to sit up in bed for short periods. What the eventual condition of the heart will be is difficult to conjecture. To Miss Benson, R. N., great credit is due, because of her vigilant and conscientious care of this child.

Total amount of antitoxin used, 33,000 units; result, recovery, possibly complete.

Case II.—Captain N., age 42. January 25, feeling unwell for about two weeks, progressive asthenia, painful deglutition, restlessness, and irritability; membrane on posterior wall of pharynx, otitis media, left side.

Amount of antitoxin used, 4,000 units; result, recovery.

Case III.—Mrs. N., wife of Captain N., exceedingly nervous, no appetite, nauseated at times during day of examination, January 25. Evidence of a mild but generalized inflammation of throat. Heart regular but weak.

Amount of antitoxin used, 3,000 units; result, recovery.

Case IV.—Lt. Mn., persistent sore throat, profound asthenia, sick ten days, no appetite, headache, cervical glands enlarged, tongue coated, breath foul, tenacious membrane on throat. Pulse 124, weak, irregular, intermittent; temperature 102.2°.

Amount of antitoxin used, 8,000 units; result, recovery.

Case V.—Mrs. Mn., wife of 2d Lt. Mn. History and clinical symptoms similar to those of her husband, but less marked constitutional disturbance had resulted.

Amount of antitoxin used, 3,000 units; result, recovery in four days.

Case VI.—Mary P., daughter of Colonel P., age 10. January 25, 1911. Croupy cough, catarrhal rhinitis, which had persisted for four days; irritable, no appetite, cervical glands enlarged, heart action was quite rapid. Pulse 132; temperature 101.6°; respiration 34. Showed diphtheria bacilli. There had been no history of difficult deglutition.

Amount of antitoxin needed, 10,000 units; result, recovery.

Case VII.—Elinor P., daughter of Colonel P., age 7. On January 27, 1911, troublesome cough, restlessness. Had several attacks of crying during the day; nauseated, pharyngeal diphtheria.

Amount of antitoxin used, 38,000 units; result, recovery.

Case VIII.—Mary S. M., daughter of Lt. Mt., age 2¾. Clinical symptoms similar to above case, but less severe in course.

Amount of antitoxin, 5,000 units; result, recovery.

Case IX.—Virginia F., daughter of Lt. Fr., age 3. Mild form of the disease. Pulse never higher than 120, and condition would have escaped diagnosis had the symptoms not occurred during an epidemic.

Amount of antitoxin used, 5,000 units; result, recovery.

Case X.—Lieut. Fr., age 30. Similar in all respects to Case IV.

Amount of antitoxin used, 2,000 units; result, recovery.

Case XI.—Lt. Arthur Bn. Severe pharyngeal diphtheria.

Amount of antitoxin used, 5,000 units; result, recovery.

Case XII.—Lt. S. D. A., age 21. Similar to above case, except symptoms of toxemia were more pronounced.

Amount of antitoxin used, 5,000 units; result, recovery.

Case XIII.—Mrs. Bt., wife of Lt. Bt., age 27. Had been unwell for several days and on January 29, at 11.30 P.M., had an hysterical attack which ended in fainting. Pulse irregular and weak, throat inflamed, membrane over the left tonsil, cervical glands greatly enlarged, breath foul.

Amount of antitoxin used, 5,000 units; result, recovery.

Case XIV.—Lucile Bt., daughter of Lt. Bt., age 5. This child was seriously ill with laryngeal diphtheria, and presented symptoms similar to those of a similarly serious case reported in the Medical Record, April 1, 1911. The lips were swollen and cracked, gums bleeding, tongue swollen, breathing noisy, and breath foul. No membrane was seen. Smears and cultures showed many diphtheria bacilli, but antitoxin was administered before the laboratory report was completed. The disease had been present in all probability for only a day or so previous to the time of examination. That same day, January 30, at 10:30 A.M., 10,000 units of antitoxin were given. Pulse 154; temperature 103.4°; respiration 52. 6:30, same date, pulse 142; temperature 104.4°; respiration 48. Antitoxin in 10,000 unit doses was administered every six hours.

January 31—9 A.M., pulse 142; temperature 102.6°; respiration 44; 10,000 units given. 8 P.M., pulse 138; temperature 103.2°; respiration 42; 10,000 units given.

February 1.—9 A.M., pulse 118; temperature 101°; respiration 28. Breathing is no longer labored and the possibility of having to intubate has passed. 8 P.M., pulse 110; temperature 101.4°; respiration 30. Breath no longer foul and appetite has begun to return.

February 2.—8 A.M., pulse 96; temperature 99°; respiration 24. 8 P.M., pulse 94; temperature 98.8°; respiration 22. Lips of normal size, no odor to breath, child seems practically well, except for a certain degree of weakness. Appetite has returned. Recovery uneventful.

Amount of antitoxin used, 40,000 units; result, recovery.

Case XV.—Franklin T. Bt., age 1¾, son of Lt. Bt. Laryngeal diphtheria contracted from his mother or sister.

Amount of antitoxin used, 25,000 units; result, recovery.

Case XVI.—Harold Pt., son of Lt. Pt., age 12. This boy had a comparatively mild pharyngeal diphtheria. There were the usual text-book symptoms barring the membrane, which was not present. Pulse 132; temperature 101.6°; respiration 30; 5,000 units

of antitoxin given on January 31, as soon as the diagnosis was made, resulted in a rapid abatement of all symptoms. February 1, 9 A. M., pulse 104; temperature 99.2°; respiration 26; 8 P. M., pulse 88; temperature 98.8°; respiration 23. Recovery was uneventful.

Amount of antitoxin used, 5,000 units; result, recovery.

These cases are cited in order to indicate the types of infection met in the epidemic and to show the varying amounts of antitoxin demanded in different cases. During the past eighteen months I have followed the advice of McCollom and Holt in administering antitoxin in twenty-four consecutive cases of diphtheria. Six of these were especially virulent forms of the disease and presented alarmingly dangerous symptoms. Yet there has been no death from the disease and no untoward effects from the use of large amounts of antitoxin. As McCollom explains, there is no way of estimating the quantity of toxin generated in any one case of diphtheria and the curative agent must, therefore, be administered in sufficient quantities and at sufficiently frequent intervals to produce the characteristic effect, viz., the shriveling of the membrane, the diminution of the nasal discharge, the correction of the fetid odor, and a general improvement in the condition of the patient. This characteristic effect may demand anywhere from 3,000 to 50,000 units or more. Large doses, he asserts, are not required in the majority of instances, and ordinarily 4,000 to 6,000 units will be sufficient. On the other hand, small doses, he contends, are of little avail in the treatment of the grave types of the disease, and in order to obtain the best results the serum must be heroically administered. Following this advice, antitoxin was given in this service of twenty-four cases of diphtheria until the symptoms disappeared or until the condition showed a marked improvement. As will be noted, 2,000 units was sufficient in one case in an adult, while, on the other hand, 58,000 units was demanded in a serious laryngeal condition (previously reported case).

Prophylactic Measures.—All inmates of houses where diphtheria was found were quarantined. No one was allowed to enter or leave these houses except for daily exercise, when they were cautioned not to converse or come into contact with other persons. Had conditions been such as to permit quarantining the patient and attendant in one or more rooms by themselves, there would have been, I believe, no occasion for restricting the actions of other members of the family in whom three successive negative cultures had proved the absence of diphtheria organisms. However, in the majority of instances, it was necessary for the parents or other members of the household to act as nurses so that all inmates were quarantined. This view of quarantine is based on Chapin's observations.

Every person in the officers' quarters, including servants and others who had been to the houses, was given a prophylactic dose of 1,000 units of antitoxin. Age in no way affected the dosage. Babies of only a few months of age received 1,000 units, and there were absolutely no ill effects noted in any of the hundred or more persons so immunized. In a few cases there were curious bone aches and a slight transient urticaria.

Quarantine and Disinfection.—After cultures taken on three successive days from the nostrils and throats of all members of the family showed that there were no diphtheria bacilli present the quarantine was discontinued.

The quarters were not disinfected, although so firmly implanted were the old ideas of fomites infection that there was considerable criticism made by various quarantined individuals as to this omission. About ten days after the last quarantine was raised I made 287 cultures on blood serum from every possible place in the supposedly "infected" houses. Floors, corners of rooms, bedding, beds, tops of pictures, toys, clothing, vases, telephone mouthpieces, etc., were thoroughly "swabbed." Without giving the tabulated findings as to the various growths obtained from each house, the following table should be of interest:

Number of cultures made	287
No growth present	19
Growth of bacteria or moulds	268
Tubes showing diphtheria	5

These diphtheria organisms corresponded to those isolated from the throats of those suffering from the disease. For the most part they could be classed as types "c" and "d," Westbrook's classification. They stained readily with alkaline solutions of methylene blue, and the granules retained their stain with Heisser's and Gram's reagents. They were irregular in form, varying from about 3 to 5 microns in length. Animal experimentation was impossible because of my rather sudden departure from the post on temporary duty. The presence of bacterial growths on the blood serum was determined macroscopically and microscopically for each tube.

Of the five tubes showing diphtheria bacilli, three were taken from the gauze covering the telephone mouthpieces, one from the hair of a doll, and one from the feet of a "teddy bear" which one of the infected children had insisted on having near her during her illness. Recovering the bacteria from the telephones was of particular interest because at the outbreak of the epidemic hospital corps men had seen that gauze was put over each mouthpiece and a bottle of 5 per cent. phenol was left on each telephone stand with explicit directions as to the necessity of moistening these gauze protectors several times a day with the disinfectant. These directions, it was later discovered, were followed during the first few days of the epidemic, but after that the dry gauze, through neglect, became a bacterial conservatory.

The last case was free from diphtheria bacilli about two months ago. The houses were not fumigated. Visitors and children have since then frequented these houses. Yet no more cases of diphtheria have developed. Thus it would appear that quarantining and disinfecting the houses is, as Chapin contends, but a minor and very subordinate method of stamping out the spread of this disease as compared to the dangers from carriers and missed cases who are not sought for or discovered, and who as a consequence come in free contact with their unsuspecting friends and acquaintances.

Summary.—1. Carriers, missed cases, and atypical or undiagnosed cases of diphtheria must be considered as of as much more importance in the spread of the disease than fomites.

2. House disinfection and quarantining healthy as well as sick inmates of a household is an unscientific method of controlling epidemics if no attention is paid to carriers.

3. A rational use of antitoxin, *i.e.* sufficient dosage at frequent intervals, will, undoubtedly, greatly reduce the present high death rate from diphtheria.

ACUTE PSYCHOSIS DUE TO BELLADONNA POISONING.

By M. ALLEN STARR, M.D., LL.D., Ph.D.,

NEW YORK.

PROFESSOR OF NEUROLOGY, COLLEGE OF PHYSICIANS AND SURGEONS.

Belladonna is known to have a specific effect upon certain persons in doses which ordinarily do not affect in any way unfavorably other persons. But the peculiar effects of poisoning, viz., dilatation of the pupils, dryness of the throat, and redness of the skin, are so well marked that the cases are easily recognized. The following cases, however, did not present these symptoms, but presented a state of mental excitement most unusual and interesting.

The first patient, a woman about 42 years of age, had been under a considerable degree of mental anxiety on account of the illness of her husband for a period of six months, and had suffered herself during that time from various symptoms caused by a chronic nephritis. She had, however, never shown any mental abnormality and was not a neurotic or hysterical character. On Saturday night she came into her husband's room in a state of mental excitement, declaring that the Virgin Mary had appeared to her at the foot of her bed with a bright light about her, and that she had become conscious of a sense of satisfaction and of peace and a conviction that she was inspired and that she was to be the mother of a second Christ, and that she had a mission to save the world. Her husband induced her to go back to her room and sat with her during the night. She talked all night, being exceedingly happy and in a state of great exaltation. She read and quoted the Scriptures freely, believing that passages in them referred to her, and was completely under the delusion that she was inspired.

I saw her the next morning (Sunday), when she appeared to be in full possession of all her faculties, but in a state of great excitement and exaltation. Her pupils were dilated, her eyes bright, and her manner and appearance had changed from her normal, with which I was familiar, as she is an old friend. She looked younger, was more quick in her speech and in her movements, and apparently much more active mentally than I had ever seen her before. She talked freely of her delusion, being convinced of its reality. She said that she saw a bright light above my head as I conversed with her in my office, and was perfectly certain that she had seen the Virgin the night before at the foot of her bed. When questioned carefully she said that there was a picture at the foot of the bed containing a figure and as she looked at that picture the figure in the picture gradually changed to the figure of the Virgin which appeared in the light surrounded by the frame of the picture. The light above my head in my office was in the same relative position as a light-covered vase upon the bookcase, hence it was evident that she was suffering from illusions rather than hallucinations,—the misinterpretation of an object seen rather than a purely subjective image. Her delusion that she was inspired and destined to reform the world was a very vivid one to her and could not be shaken by any argument, as she regarded any criticism of it as worthless. She believed that she had a mission to perform to save everyone about her and was ready to talk freely of this mission.

The very unusual character of the delusion and its sudden appearance led me to the idea that this psychosis might be the result of some toxic state. On questioning her I found that for some time she had been taking a capsule containing ¼ grain of belladonna, and had gradually increased these capsules from one up to three daily without any apparent ill effect. They had been taken for two months. A new supply of these capsules had been obtained on Friday, the day preceding the onset of this psychosis. Her pupils were dilated but her skin and throat were not dry, there was no erythema upon her body, her pulse was rapid (100 in the office and later 94), and her knee-jerks were slightly exaggerated.

On the supposition that it might be a case of belladonna poisoning and that she had obtained an overdose of the drug, on account of the carelessness of the druggist in compounding the capsules, which were found to call for one-quarter of a grain of belladonna in each capsule, but which had been put up to the number of thirty capsules at one time, I ordered them to be stopped and prescribed valerobromine, a preparation of bromide of potash with valerian, in a rather large dose. She slept quietly on Sunday night but her delusions and illusions were equally present on Monday. On Tuesday she seemed to be quieter and less excited and the illusions were no longer present, though the delusion persisted. By Thursday she had ceased to talk of the delusion, but when questioned seemed to have no doubt about her mission and her inspiration. By the end of the week this had faded away and the following Sunday she was willing to admit that there had been no basis for the idea, though she insisted that it was very real to her mind at the time. All symptoms had passed away completely at the end of the eighth day from the onset, and she has been perfectly well ever since, viz., over a period of twelve weeks.

The possibility of this psychosis being due to belladonna poisoning was suggested to my mind by an experience not unlike this which occurred ten years ago.

A young man was brought to me by his brother suffering from a state of great nervous excitement and exaltation and with delusions of wealth and of power wholly out of proportion to his means and capacities. This had come on suddenly twenty-four hours before I saw him, and had alarmed his brother, who felt that it might be necessary to place him in an asylum at once. He had no hallucinations or illusions, but was in a state of great exaltation with marked delusions of grandeur. He had no physical signs of general paresis. On questioning I found that he had been suffering during the previous week from a severe attack of lumbago, and on stripping him to examine him I found two large plasters ovet his back which he said had been recommended by a druggist and which were marked "belladonna plasters." His pupils were widely dilated, but he had no dryness of the throat and no eruption on the skin. I removed the plasters, had him take a long Turkish bath, and prescribed bromide freely, and in 48 hours his brother brought him back in a state of good mental equilibrium so that within two days thereafter he was able to return to his ordinary occupation in a state of perfect health.

I put these cases on record inasmuch as they have been to me of considerable interest, and they enforce the fact that the sudden development of illusions, hallucinations, and delusions in a previously healthy person should always awaken the suspicion of a toxic psychosis. A search through the literature has failed to reveal any similar cases on record, though

cases of ordinary belladonna poisoning are not uncommon. Authors on toxicology have mentioned the fact that belladonna may produce a sense of self-satisfaction and semi-exaltation, and cases of psychosis due to hyoscyamus are not unknown in the literature.

POSSIBLE CAUSES OF FAILURE FOLLOWING THE USE OF BACTERIAL VACCINES AND ANTISERA.*

By H. E. PLUMMER, M.D.,

NEW YORK.

ASSISTANT SURGEON OUT-PATIENT DEPARTMENT, ST. LUKE'S HOSPITAL.

"The most mischievous ignorance is that of the critic." So many unjust criticisms are heard relative to the value of bacterial vaccines and antiserum in the treatment of infections, that the above quotation of Voltaire seems scarcely out of place. Some reports indicate such successful results and others such absolute failures in similar cases that they stimulate us to inquire into the reasons for such diversity of conclusions. May not these failures be in part due to faulty dosage, to incorrect intervals elapsing between the doses, to a wrong appreciation of the benefits to be expected from the use of a bacterial vaccine or antiserum, and to a faulty selection of the remedy to be used? Let us first study briefly the qualities of a bacterial vaccine and of an antiserum and the theories upon which their use is based.

Antisera are obtained from some bacteria that do not produce extracellular toxins in sufficient quantities: as, for example, the streptococcus and the gonococcus. The germs themselves are injected into the animal, first in minute doses of greatly attenuated cultures, then in gradually increasing doses until such a resistance exists in the animal that large amounts are tolerated. These antisera may be said to possess antibacterial power. The fact that antisera are elaborated in the horse distinguishes them from bacterial vaccines which are simply suspensions of killed bacteria in physiological salt solution. From this it may be seen that when antisera are used the patient is inoculated with the protective substances produced by an animal whereas when bacterial vaccines are injected the patient must produce his own protective bodies.

Wright and others have demonstrated the fact that there are substances in the blood stream that assist, or are necessary to aid the phagocytes in their successful warfare against invading bacteria. If, however, Nature's laboratory is unable to completely overwhelm them at once, the destruction of a portion of the invading host will produce a strengthening of the defending force. This is known as autoinoculation and is best illustrated in the pneumonic crisis. In some infections the protection afforded is lasting, as in smallpox and in yellow fever, while in others, as in tuberculosis, the protection is transient. When Nature is able to cope with the infecting bacteria, self-immunization is likely to take place. This is due to the death of a certain number of the organisms and their immediate effects as immunizing agents. The artificial introduction of a suitable number of dead microorganisms, *i.e.* the injection of a bacterial vaccine, may turn the scale and produce the reinforcement necessary to Nature, which at the moment is so urgent. As a result of the injection of these bacterial products such indefinite substances as bacteriolysins, precipitins, agglutinins, and opsonins are produced. The latter, which are measurable, act on the bacteria in such a way as to make them more vulnerable to the attacks of the phagocytes. The phenomena accompanying spontaneous recovery from an infectious disease, and which for a time at least prevents a new attack, we term natural acquired active immunity. That produced by the injection into the tissues of small quantities of living or killed microorganisms or of toxins produced by these organisms we call acquired active immunity. "In passive acquired immunity on the other hand the patient does little or nothing toward obtaining this immunity. The toxins, which characterize the disease are simply neutralized or rendered inert by the injection into the individual of protective substances, which have developed in the serum of another animal, as the result of active immunization. This form of immunity is a temporary expedient, which simply serves to hold the disease processes in check sufficiently long to permit Nature to manufacture and bring into play such protective and bactericidal substances as will rid the individual of the offending bacteria and their toxins."

The opsonic index is the comparative phagocytosis of the patient's serum to a normal pool serum. The technique is complicated and the slightest inaccuracy produces decidedly varied results. The index has proven of great value in indicating the proper dosage, frequency of injection, and results obtained. It has been found that the careful observation of the clinical symptoms acts as a sufficient guide to the treatment by bacterial vaccines in the more common infections. By determination of the opsonic index Wright has demonstrated that following the injection of vaccines, there is first a drop in the opsonic index and later a rise. This drop he calls the negative phase and the rise the positive phase. The use of bacterial vaccines in infections is clearly defined. It is useless to suppose that every case of infection is a suitable one for this treatment. The question is of necessity whether the patient is capable of producing antibodies to the infecting agent or whether they should be introduced from without, *i.e.* from an animal already immunized to the infecting agent.

A case occurs to me of a patient infected by an attenuated strain of streptococcus which ran a chronic course. A culture was obtained and an autogenous vaccine prepared and administered at intervals. The patient continued to grow worse and ultimately died. This patient was already so surfeited with streptococci that the introduction of a few million more dead germs seemed scarcely the rational treatment for such a condition. Had such a patient the power to produce his own antibodies, it would appear rational that he would have produced them with the many streptococci swarming in his system, without the introduction of more. Thus antistreptococcic serum should have been first used to modify the infection. Therefore in general septicemias the serums are indicated; whereas in localized or semi-localized conditions the bacterial vaccines are to be preferred.

*Read before the West Side Clinical Society.

In reviewing the important subject of dosage we find a great variety of opinions. There are, on the one hand, the advocates of small doses and, on the other, those of large doses, but no set rule can be laid down for the administration of bacterial vaccines. The guiding factor in these cases must be more or less the resistance of the individual to the infecting organism and therefore the ability of the tissues of the patient to produce antibodies. Overdosage has been a not infrequent cause of absolute failure. It has often been noted that the administration of 400,000,000 staphylococci in cases of furunculosis has produced an increased number of pustules or furuncles instead of benefiting the condition. In other words there has been a production of a prolonged or more severe socalled negative phase, thereby allowing the invading bacteria to obtain the mastery over the protecting forces of the blood stream. During the aggravated or very violent stage of the infection one should not administer a vaccine, as the activity of the infecting agent itself may be producing a negative phase.

No definite time can be positively made as to the proper interval for reinoculation, but in every case sufficient time should elapse between injections to allow the formation of the high wave of the positive phase. In scarcely any instance should the interval between the administrations be less than three days or in very rare instances more than seven days, the average time being about four to five days. An instance has occurred to me in which bacterial vaccines were administered in maximum doses daily and it was noted that the patient was gradually becoming worse. The treatment was therefore discontinued and at the end of the second day, most marked improvement was observed in the condition of the infection. The lack of improvement was undoubtedly due to the fact that the patient was kept in a constant state of negative phase.

Freeman working in Wright's Laboratory, noted the occurrence of autoinoculation following the manipulation and massage of affected joints in gonorrheal arthritis. Therefore in the handling of localized infections one must always bear this fact in mind; that following any form of treatment; be it massage, *x*-ray, electric, radiant heat application or Bier's hyperemia, observations have shown the regular sequence of positive and negative phase and phase of increased resistance, identical with that produced by an ordinary vaccine prepared from the invading organism. Therefore when treating a patient with bacterial vaccines care must be taken to avoid over-manipulation of the infected area, as this may result in self-inoculation which would be equivalent to an overdose of bacterial vaccine.

On the other hand, knowing as we do that the opsonins render the bacteria vulnerable to the phagocytes, it is very important to the success of the treatment that the lymph be made to flow through the infected tissues. In cases of infection, English authorities advise the use of a wet dressing composed of 4 per cent. sodium chloride and .5 per cent. sodium citrate. This solution is an ideal lymphagogue, and prevents, by inhibiting coagulation, the formation of a scab. Let us remember also that leucocytes are essential to the success of vaccine therapy and that the best results may be expected when large numbers of healthy leucocytes are present. MacWatter claims that the leucocytes may be increased in number six or seven fold by the administration of yeast. This method is rather crude, as no definite amount of nucleinic acid is administered. As the success following the use of yeast in these cases is undoubtedly due to the nucleinic acid which it contains, it would seem more scientific to use nucleinic acid which, under the name of nuclein solution is readily obtainable.

Some failures are due to the selection of unsuitable vaccines, as the following case will show: A young man suffering from chronic prostatitis came under my personal observation. Improvement was obtained by the use of gonococcus vaccine, but it seemed impossible by this means to effect a cure. At this stage, I resorted to the use of a combined vaccine made from a mixture of common pyogenic organisms. The results of these injections were very gratifying. In this case, though the infection was primarily due to the gonococcus it is evident that other organisms replaced, at least in part, the one named. It should be borne in mind that though a specific organism may be the original cuse of the trouble the advent of other germs producing a mixed infection may delay a cure and, in the absence of indications to the contrary, it may be well in such cases to employ such a mixture of vaccines.

Conclusions.—1. There should be a proper determination of whether an antiserum or a bacterial vaccine is indicated. 2. Care should be exercised in deciding on the proper dosage for each individual infection. 3. The administration of vaccines during the aggravated stage of infection may produce harmful effects. 4. A proper interval should elapse before repeating the injections. 5. Too much local treatment of the infection may produce harmful results. 6. Such aids as tend toward the increase of leucocytosis or the freer movements of lymph should be given to assist the effects of the bacterial vaccine. 7. Any possible change in the character of the infection should be observed.

111 West Seventy-seventh Street.

STOKES-ADAMS DISEASE; THE STATUS OF HEART BLOCK; REPORT OF CASES.*

By JAMES C. JOHNSTON, M.D.,

M'ALESTER, OKLAHOMA.

SUPERINTENDENT ALL SAINTS HOSPITAL.

Adams-Stokes Syndrome, Adams-Stokes disease or heart block, is a non-contagious and a non-infectious disease believed to be dependent upon the pathological changes in the auriculoventricular bundle, and manifested by a permanent or recurrent bradycardia, to which may be added dizziness, syncope, apoplectiform attacks, or epileptoid seizures. There seems to have been no publicity given to the disease as a symptom complex until 1883 when Gaskell demonstrated the excitability of nerve-free heart muscle from a tortoise. Prior to this time it was generally believed that the cardiac cycle was wholly dependent upon the neurogenic action.

*Read before the Pittsburg County Medical Society, February 14, 1911.

During 1893 Stanley Kent isolated a bundle of modified muscle fibers which connected the auricles and ventricles, and proved the conductivity of this bundle for stimuli. In 1894 W. His, Jr., elaborated the previous researches and demonstrated the anatomic relations and functions of the auriculoventricular bundle, which came to be known as the bundle of His.

The bundle is about three-fourths of an inch long, one-tenth of an inch wide, and one-twentieth of an inch thick. It pierces the interauricular septum from the right to the left side, and its branches freely ramify in the ventricles. The guide to its location is the anterior end of the attachment of the septal cusp of the tricuspid valve. The bundle bridges the auriculoventricular groove. The auricular portion of the bundle is composed of very fine fibers containing many nuclei. The ventricular portion is composed of fibers not unlike those of Purkinje. It is stated that the structure of the bundle comprises a third variety of heart tissue.

The pathology of Adams-Stokes disease concerns the auriculoventricular bundle principally, and the findings have been fatty degeneration vascular changes, calcareous deposits, which later crowd out the fibers of the bundle, and infarcts in the interauricular septum. The frequency with which arteriosclerosis of the vertebral, basilar, and coronary arteries appeared gave rise to a consideration of these conditions as integral parts of the disease. But that the disease is due to the crowding of the fibers seems to be well shown by the recent experiments of Erlanger, at Johns Hopkins. He produced artificially the clinical symptoms of heart block in a dog by placing a clamp on the heart at the level of the auriculoventricular groove. A slight pressure of the clamp produced only a delay in the ventricular beat; moderate pressure caused an occasional dropping of the ventricular beat. Greater pressure produced a variation in the ratio between the auricular and the ventricular beats as 4 to 1. Under severe pressure, which was still insufficient to crush the fibers, the auricles and ventricles beat independently of each other. Excessive pressure caused a cessation of ventricular action, while destruction of the bundle by pressure caused a complete heart block which was permanent, as there was demonstrated no effort of a reparative nature.

The objective symptoms are bradycardia with alteration in the ratio of 1 to 1 in the rhythm of the auricular and ventricular sounds. The radial pulse may be 40, 20, 10, or even lower. If there is no wide departure from the normal rhythm no untoward effects are noted. Subjectively there are no very early symptoms. Even considerable variation of rhythm may be unnoticed, and the knowledge of the existence of the condition may be accidentally acquired as during a heart examination by a physician. With the progression of the disease, however, there occur the usual symptoms of a failure in the circulation, notably, shortness of breath, diminished muscular power, momentary mental confusion, dizziness, tinnitis aurium, and cold extremities. Later, there occur syncopal attacks, epileptoid seizures, or apoplectiform attacks. The convulsive form is witnessed only in the marked cases.

Physical Signs: Inspection shows pulsation of the cervical veins, particularly the internal jugulars, which corresponds to the auricular contractions, but does not correspond to the apex beat. The sphygmographic tracings show an intermittent pulse with a low arterial tension and lack constancy in outlines. On palpation there is pulsation in the veins which rises slowly and falls rapidly, while the pulsation in the arteries rises quickly and falls slowly. By comparing the two, the ratio of the vein to the artery impact will be felt as 2 to 1, 3 to 1, or even with a wider variation from the normal rhythm of the heart. On auscultation: The second sound predominates in frequency and is not preceded regularly by the first sound, neither are the pitch and timbre of the first sound uniformly constant, but are subject to variations and tend to become weak and indistinct.

Clinical Varieties: Probably no gain would result from a classification into acute and chronic forms, though symptoms follow closely enough to permit of such a consideration. Terminations: Cases presenting only an occasional drop of a ventricular beat have improved under treatment, and apparently have recovered. The marked cases are less amenable to treatment because, at this time, no remedy has induced a reparative process in the bundle, after its integrity has been materially interfered with by degenerative processess. Complications: Septic endocarditis, valvular diseases, arteriosclerosis and a lowered resistance to other diseases. Diagnosis: The multiple auricular contractions related to the single ventricular systole do not occur in epilepsy, apoplexy, and convulsive states, and the history is foreign to these diseases, so that a careful examination should render the diagnosis reasonably certain. Prognosis: The condition being truly organic, a prognosis should be guarded. There is no absolutely certain method to measure the resisting power of the bundle, or to calculate the amount of damage already sustained.

Treatment: Remembering that the intricate mechanism of the heart is, to no small degree, dependent upon the ganglia within, as well as the nerves entering the heart, an analysis of the syndrome should incorporate the physiological phenomena, in order to devise a rational plan for the return of the partly blocked heart to the normal cycle. The two motor ganglia are those of Remak and Biddle, and are situated respectively in the opening of the inferior vena cava, and in the auriculoventricular septum. The sensory ganglion, that of Ludwig, which is inhibitory in action, lies in the interauricular septum. The pneumogastric nerve, together with some filaments from the spinal accessory, gives off branches which reach the inhibtory ganglion. The accelerator fibers from the medulla pass into the seventh cervical and first dorsal ganglia of the sympathetic nerve, whence the heart receives additional stimulation. Since heart block is dependent upon the disturbance of transmission of the exciting energy from the ganglia to the ventricles, it appears that an agent which would paralyze the inhibitory terminal filaments would permit of the increased stimulation being crowded over the point of resistance, which is the bundle of His, and into the ventricles. Atropine does this to a great extent, as stated by Hare in the report of a case in which the ratio was 140 to 40, and which, under atropine, became 70 to 70. He disparages the use of digitalis, believing it fatal in severe cases, and only to be used in very mild and imperfect cases of heart block. Caffeine increases the cardiac contraction and duration of the systole, shortening the diastole, and consequently is not indicated if the disease is at all far

advanced. In early stages strychnine may be thought of, as it stimulates the motor ganglia; but as it also acts upon the medullary vasomotor center and causes a rise in the resistance to the arterial flow by a contraction of the blood vessels, and lengthens the diastole, it, like caffeine, becomes of secondary value to digitalis, and digitalis is less remedial than atropine.

Case I.—Mrs. R. B. C., age 29, housewife. Family history negative, previous health splendid, with the exception during the past three years of periodical attacks of cervicooccipital neuralgia, which occurred on an average of every forty days and lasting for thirty-six to forty-eight hours. The attacks developed gradually. Coal tar derivatives and opiates were used under the direction of physicians only, but without entire relief of the paroxysm earlier than twenty-four to thirty-six hours. When I was first called to the case the pulsation in the neck was plainly visible and so rapid that I expected to find considerable temperature. However, the radial pulse was only thirty to the minute. Auscultation revealed the fact that the pulsation in the neck was synchronous with the auricular contraction, but the radial pulse corresponded to the ventricular systole only. A consultant diagnosed the case as one of meningitis, and took charge of the patient, as I withdrew, not agreeing. The further history was that the patient suffered much pain (occipital) and had fainting attacks follow her efforts to rise from the bed. This condition lasted three hours and she passed into an epileptoid state. Upon effort to stand up she collapsed. Autopsy was refused.

Case II: C. P., age 30, Italian miner. Family history, neurotic mother. Previous health, "stomach trouble" (gastritis), two years. He complained of a choking sensation after slight exertion, was easily fatigued and slept poorly. On examination of his heart, the ratio of the auricular contraction to the ventricular systole was 90 to 87. The patient died suddenly during a debauch a week later.

Case III: G. G., age 40, American. Previous history good. Examination for fraternal life insurance revealed an occasional drop of the apex beat, although the auricular contractions were regular. When told of the condition which would debar his participation in the insurance benefits, he expressed surprise that his heart was unsound, as he had never had cause to suspect trouble from this source. After three years, his physician informs me, that the patient is apparently well, that he has received no treatment, and has experienced no discomfort. The irregularity in heart action, however, is no better.

A NEGLECTED PHASE OF THE PREVENTION OF SUMMER GASTROENTERIC DISEASE IN INFANTS.

By LE GRAND KERR, M.D.,

BROOKLYN, N. Y.

VISITING PEDIATRIST TO THE METHODIST EPISCOPAL (SENEY), THE WILLIAMSBURGH, THE BUSHWICK AND THE SWEDISH HOSPITALS IN BROOKLYN, N. Y. CONSULTING PEDIATRIST TO THE ROCKAWAY BEACH HOSPITAL, THE INDUSTRIAL HOME FOR CHILDREN, ETC.

The time to commence treatment of the summer diarrheas of infants is in the late spring or at the latest the early summer. Gastroenteric disease, as it is expressed in infants and young children, is not always an acute process. In fact, although it appears as an acute condition, it is uncommonly such, and careful history taking will almost invariably reveal the fact that the acute process is one that is developed upon a soil which has been long prepared for it. It is a fact that is commonly observed and taken advantage of that careful management of the feedings and adequate supervision of the hygienic surroundings of the infant will prevent or limit digestive disturbances. But it is not always so commonly noted that the avoidance of repeated digestive disturbances prevents the occurrence of serious disease in many instances.

Thus the prevention of digestive disturbances is the largest factor in the limitation and prevention of acute gastroenteric disease. In the treatment of the summer gastroenteric disturbances, the prophylaxis demands that the digestion be normal or nearly so. And in calculating this factor we cannot put too much reliance upon the single factor of weight. Although weight is often a splendid indicator of the nutrition, it is not always so, and in estimating its value we must also pay considerable attention to the elements of comfortable digestion and the evidences of perfect assimilation. Serious summer gastroenteric disease is not often sudden in its onset but may often be predicted because of the general condition of the infant; a condition which favors its development from a slightly active cause. On the other hand, the general condition may indicate that summer gastroenteric disease will be successfully resisted. Thus if the infant experiences a normal, restful sleep, has regular and adequate bowel evacuations with a normal, well digested stool, has an oral cavity which is undiseased and kept clean, and is happy, contented, and playful, it will probably entirely escape serious gastroenteric disease or if infected will exhibit an immediate and successful resistance.

Contrary to this, we constantly observe infants who are the victims of frequent attacks of more or less severe vomiting, gastric or intestinal distention, with irritations of the anal region or the napkin area, with daily but inadequate bowel evacuations, or evidences of undigested food in the stools, or who suffer from sore mouths, in whom we can almost certainly predict that with the onset of a short but continued spell of hot weather there will be the occurrence of serious disease with an uncertain termination. Therefore, as far as summer gastroenteric disease is concerned, prophylaxis must take recognition of the most trivial symptoms which precede it and are in any way attributable to the digestive tract. Not alone in July and August, but in May, June, and September, any digestive disturbance in an infant, and particularly in those under nine months of age, should be regarded as the possible beginning of a fatal disease.

When the disease is once fully established, prophylaxis is restricted to the prevention of general disease and the avoidance of accidental complications. In the accomplishment of these objects there are several things that must be done. These might be briefly summarized as follows: (1) The expulsion of the offending material from the stomach or bowel. (2) The dilution of the toxins. (3) The introduction of a food that is completely suited to the immediate needs and the securing of its absolute cleanliness and freshness. (4) The establisment of adequate hygiene of the mouth. (5) The maintenance of a clean skin, particularly that of the napkin area. (6) The protection of the food by clean utensils and careful attendants. (7) The protection of the infant by clean, fresh air and the best possible surroundings. (8) The isolation of the patient sufficiently to protect other children.

As the purpose of this paper was to draw atten-

tion to one phase of the treatment of summer gastroenteric disease which is often neglected, it is unnecessary to go into detail in regard to the above. Local conditions and individual necessities and possibilities are so varied that in the working out of the details the individual attendant is the best judge of what methods to establish. But we might reiterate what has already been said, that the time to treat summer gastroenteric disease in infants is before the disease has had an opportunity to become established. This seasonal disease requires seasonable treatment.

42 Gates Avenue.

A CASE OF PULMONARY TUBERCULOSIS WITH HEART DISPLACED TO RIGHT SIDE.

By HORACE GREELEY, M.D.,
BROOKLYN, N. Y.

A case of what appears to be a displacement of the heart from the left entirely to the right side is of sufficient general interest to justify a brief account of the patient's history and present condition, and the results of physical examination:

M. M., a native unmarried woman of 22, of no employment, gave a history of having suffered from pulmonary tuberculosis for eleven years, and of having been always more or less of an invalid. She was 5 feet 6 inches in height, with maximum weight of 118 pounds, though when she came under observation a month ago it was 100 pounds; she was anemic, had a very slight cough, with an expectoration amounting daily to one or two drams and an afternoon temperature of about 99° F. The pulse and respiration, sitting, were 90 and 24 respectively. Chest—Right side, anteriorly, much depressed, very slight expansion. Right and left hypochondriac regions show marked transverse constriction, evidently produced by shrinkage of chest contents followed by its shell, which below was still held out by the abdominal organs. Repeated percussion and auscultation of the patient's chest show but slight infiltration of the left apex, but the entire lung is hyperresonant and the breathing sounds are much prolonged. There are no signs of the heart on the left side, the lung completely filling this part of the thorax. On the right side, tympany and cavernous breathing are so general as to leave no doubt but that what was once the right lung is now but a mass of strings and cavities. A few large râles are sometimes heard. On this side the heart is outlined: above, upper border of the third rib and cartilage; below, lower border of the fifth rib and cartilage; externally, by a perpendicular line from anterior axillary fold; and internally by a perpendicular line drawn about one inch from the margin of the sternum. Valve sounds are best heard as follows: mitral, where the apex beat may be seen and felt, in the sixth interspace, one inch from the sternum; aortic, over third cartilage, one inch from the sternum; pulmonic, in the mid-sternum between the right and left third intercostal spaces. The mitral sound seems to be imperfect owing probably to a slight regurgitation. The liver and the spleen seem to be normally located. The patient's only complaint is of cardiac palpitation which keeps her awake at night, and a dragging sensation, constantly present around her heart. She is most uncomfortable when lying on her right side. Under hygienic treatment during the past month she has gained about six pounds and is feeling and looking much better.

Cancer and the General Practitioner.—Sir A. P. Gould states that if all practitioners would make a practice of sending to the operating surgeon a brief record of every case of cancer that has been treated by operation, whether it show recurrence of the disease or not, and particularly would notify the surgeon of the patient's death, and whether in the event this is due to cancer or not, one's knowledge of the real value of operations for cancer would soon become more nearly exact than it is at present. —*Practitioner.*

Citrate of Soda in the Vomiting of Infants.—G. Variot advocates the use of the citrate of soda, not only for modifying milk so as to render it more digestible, but also for preventing vomiting in all sorts of infantile troubles. It has the effect of quieting the muscular peristalsis of the stomach. It makes no difference whether the child vomits from too much or too little milk, or because the milk does not appear to agree with him. The drug has an almost immediate effect for good, which is astonishing to the mother. It prevents infantile scurvy also. The author gives these statements as a result of personal observations made by him in his hospital service. He uses a solution containing in one tablespoonful 25 centigrams of the drug. It has been found to be perfectly harmless even when given for a considerable period and in large doses. One need not fear that the salts of lime will be precipitated in any considerable quantity by its use.—*Revue de Thérapeutique Médico-Chirurgicale.*

Extraction of Upper Teeth with Intranasal Anesthesia.—Richter advises the insertion in the nasal fossæ of pledgets of cotton soaked in 10 per cent. cocaine solution. These are introduced on the side to be operated on. Another pledget soaked in 1:1000 suprarenin solution is then inserted. The cotton is allowed to remain *in situ* for fifteen minutes. Pledgets should be 4 cm. long and placed upon the floor of the nasal chamber. The object of this anesthesia is to reach the nerve filaments which supply the teeth. In most cases it is possible to extract the incisors without pain, doubtless because the alveolar nerves are reached by the diffusion of the solution. It is possible that a more extensive analgesia is obtainable if a less toxic analgesic is thrown directly into the antrum. This would necessitate puncture of the inner wall of the latter. Another suggestion is a submucous injection in the floor of the nasal chambers. If these methods are practicable they should possess advantages over infiltration of the gums.—*Arehiv für Laryngologie.*

Radiotherapy in Acute Adenitis.—F. Jaugeas says that the use of the *x*-rays is the treatment of choice in tuberculous adenitis when it has not yet suppurated, and should be used as an adjuvant to operation in tuberculous abscesses and rapidly developing adenitis. The benignity of this treatment makes it acceptable to the patient and renders it easier to get him to submit to surgical operation. Its action is rapid and complete in non-suppurative cases. It depends on a reduction of the lymphoid elements, and in single glands is very rapid. When several glands form the mass the connective tissue of the periadenitis which joins them into one mass is not so easily absorbed. When caseation has occurred and abscess has formed it is necessary to first evacuate the abscess through a very small opening and then to apply the rays in sufficiently strong doses to produce an immediate effect. Such a strong application is greatly superior to several weaker ones, which may cause an irritation favorable to the development of the swelling. The esthetic results obtained by this method are much to be preferred to the formation of scar tissue after operation, and the mass is affected throughout in such a way that the neighboring glands do not enlarge afterward, while, after operation, other glands may enlarge and the difficulty be repeated.—*La Presse Médicale.*

INJURY AS A CAUSATIVE FACTOR IN CANCER.

WHATEVER theory we may hold as to the cause of malignant disease, whether it is of extrinsic or of intrinsic origin, it must be conceded that chronic irritation or oft repeated small traumatisms play a definite rôle in the localization of malignant disease in the human organisms. The frequency of cancer of the uterus and of the female breast, of the lip in pipe smokers, of the scrotum in chimney sweeps, of the hand in *x*-ray workers, shows that the changes produced in the tissues by chronic irritation or oft repeated traumatisms predispose these tissues to malignant degeneration, once the tendency to malignant disease is present or has developed in any given individual. On the other hand the part played by single more or less severe trauma in the causation of cancer has been a subject of great dispute and the majority of observers are inclined to deny any relation between trauma of this nature and malignant disease. The tendency of the laity to trace all non-infectious disease accompanied with alteration of form to recent or old injury is usually remembered in discounting any history pointing to such a relation. Yet it is possible to lose sight of partial truths in denying or disbelieving partial error and that this is the case in the subject of trauma and cancer is the view of William B. Coley, who publishes a very important article on this theme in recent issues of the *Annals of Surgery* (April and May, 1911). For over twenty years Coley had an unparalleled opportunity of observing malignant disease, because of his well-known activity in advocating the mixed streptococcus and prodigiosus toxins in the treatment of sarcomata, and is therefore well fitted to discuss the question raised by him.

In all Coley has observed 970 cases of sarcoma in which careful histories were taken. Of these, 225 cases, or twenty-three per cent., gave a definite history of trauma preceding the disease, and in over one-half of these cases the tumor developed within the first month after injury. So far as the localization of the tumor is concerned, among bones, the femur, the tibia, the fibula, the ilium, and the clavicle, bones notoriously exposed to injury, gave the greatest number of cases of malignant disease; among soft parts, the thigh, the breast, and the pectoral region, and the testicle were most frequently affected. Of course, in the majority of cases, there was simply the history of trauma, followed by the appearance of a tumor at the exact site of injury. That the trauma may simply have called the attention of the patient to the already existing tumor, or that trauma and tumor may simply have been coincident and not at all related, may of course have been true in many instances. Considering the nature of the matter, it is easy to see how another element in the proof of relation of tumor and injury, namely, a medical examination of the condition of the parts before the injury, should be usually lacking.

However, if this deficiency is supplied in several typical instances these may be accepted in strengthening the chain of proof in other cases. Coley supplies this deficiency in at least four very important instances. In one, an injury resulted in a fracture of the femur, the *x*-ray at the time showing normal structure of bone in the fragments; another *x*-ray examination, six weeks later, showed a well developed sarcoma at the seat of fracture. The second instance was that of a sarcoma, starting at the exact point of a surgical injury, a hernia incision made four weeks previously. The third was a sarcoma of the malleolus, three weeks after an injury incidental to a forcible correction of a flat foot. The fourth case, finally, was a sarcoma of the femur in a girl of nine years, following a fall from a bicycle.

Coley concludes that local trauma is not infrequently the direct exciting cause of a malignant tumor, and that our inability to explain the relationship between trauma and tumor should in no wise lead us to deny such a relationship. When the difficulty in explaining the various manifestations of a tuberculous infection before the exciting cause of tuberculosis was discovered is remembered in this connection, it must be granted that Coley's point is well taken. The wealth of material he presents necessitates the provisional acceptance of his conclusions until better knowledge of the causation of malignant disease has been arrived at.

THE DOOM OF THE WHITE MAN.

MUCH has been written at one time and another regarding the ability of the white man to live in the tropics and to retain his bodily and mental vigor. The consensus of opinion has been that he cannot do so, but that after a time he will surely deteriorate, physically and mentally. Furthermore, white natives whose ancestors have lived three or more generations in the tropics are not, with rare exceptions, the peers either in body or mind of their relatives living in the temperate zone.

Prof. Lionel W. Lyde of London University has recently written most pessimistically on the subject. Not only does he hold that the white man cannot live in health in tropical countries, but professes to believe that the white man is doomed to vanish from the face of the earth, giving way to the colored races. The English professor bases his belief on the theory that the original color of the human skin was dark brown, the variations of that color being the results of the weakening or strengthening of the pigment under different climatic conditions. The rays of sunlight in the tropics on an individual

unprotected by a dark skin have the effect of producing nervous shock, amounting sometimes to total prostration.

Taking ordinary precautions, it may be possible for the white man, after two years of acclimatization, to live in the tropics even more immune from tropical diseases than the black. But this period of immunity lasts for only about seven years, after which the deteriorating effects of the strong solar light and heat begin to show themselves on the white skin, and render the possessor thereof peculiarly susceptible to tropical diseases. In consequence, the permanent settlement of the tropics by white men is impossible. But while the pigment with which the colored races is provided is indispensable for life in the tropics, it is a source of no danger in the temperate or frigid zones; therefore the dark or yellow man can intrude into the domain of the man of fair skin with little or no danger. Added to this may be placed the comparatively greater fertility of the dark races, and, in the opinion of Lyde, the doom of the white man is inevitably suggested. His part it is, therefore, in the scheme of the world, to train the dark-skinned races in all the arts and sciences, including the art of government, and then himself to get off the earth.

HYPERHEDONISM.

This term was devised by Ziehen to indicate that condition of excessive sexual excitability which he believes to form a substratum for all kinds of sexual aberrations. Stier, at a recent session of the physicians of Charité Hospital, Berlin (*Berliner klinische Wochenschrift,* No. 10, p. 451), endorses Ziehen's hypothesis and cites two cases of sadism in young boys. Heredity plays a determining rôle, and both the boys were born out of wedlock, thus presumably of hyperhedonic stock. They exhibited all the qualities which are absent in normal boys. They showed great sexual precocity, yet were not technically onanists. They were highly neuropathic in temperament. With lust notably developed there was no natural outlet, but instead the common association of cruelty. We find the latter, however, without lust, and the boy who tears the wings from flies, as well as the teamster who aimlessly beats his horse, cannot be held as hyperhedonists. The boy is actuated by curiosity, while the driver is stupid and thoughtless, and his whip, like other implements, suggests its own use.

In associating lust and cruelty the latter must be of a peculiar type and have a special bearing on the former. Certain types of cruelty are associated with certain lustful acts. Cases like those cited by Stier would be set down ordinarily as due to moral imbecility in regard to sexual matters in individuals otherwise normal, save for a possible psychopathic taint. Such subjects may have no prejudice against incestuous relations; as an old moralizer in the Elizabethan era said, there are two kinds of atrocious crimes, one open and palpable, made up of offences like murder and arson, while the other has a mere technical or sacrilegious significance—a sin instead of a crime. Under the latter head he placed incestuous relations.

It is evident that a wide gulf exists between sexual hyperesthesia and hyperhedonism—yet it must be difficult to draw a sharp line here. Some of the worst known onanists have been men who had normal sexual relations with women on every possible occasion. These are pure sexual hyperesthetics, and are not often encountered in practice. It is not often that these subjects are accused of sexual perversity of any sort. Masturbation is the spontaneous or instinctive method of relief from congestion of the testicles. Copulation with woman is a sort of ideal, to attain which a man will go to extremes of venture. But this is a simple sexual hyperesthesia, with no element of perversity. A sexually hyperesthetic man need not have incestuous longings, nor need he be a pervert.

It is evident that Ziehen, in introducing the subject of hyperhedonism, intends it to cover almost the whole of sexual perversity. Natural or quasi-natural sexual relations do not belong here. The desires which are satisfied in a variety of instinctive and opportune ways, however repulsive some of these may seem, have nothing in common with hyperhedonism, which may be regarded as almost wholly perverse in character—an equivalent, so to speak. The distinction is a very practical one, which will appeal to all practitioners.

HAS THE HYPOPHYSIS AN EXTERNAL SECRETION?

The hypophysis continues to be classed among the closed or ductless glands despite the fact that for some years claims have been put forward that a quasi-external secretion may be present. Edinger, in a paper read recently before the Scientific Union of the Frankfort City Hospital (*Münchener medizinische Wochenschrift,* April 4, 1911), states that there are two as yet unsolved problems in connection with this organ. One is purely embryological, concerning the connection of the hypophysis, which is evolved from the pharyngeal epithelium, with the brain, a relationship universal in mammals.

The other problem refers to the question of an external secretion, regarded by the author as proven to exist. The older view was that the secretion passed directly from the epithelia into the blood-vessels and was therefore wholly internal. The author succeeded, however, by injection methods, in demonstrating that all hypophysis cells are surrounded by hollow spaces, which form secretion tubules between the epithelial tubes and their surrounding blood-vessels. The secretion tubules find their way into the lymph system of the brain, and the secretion is discharged directly into this organ. There is, of course, a direct connection between the blood-vessels of the hypophysis and those of the brain. From this viewpoint, which the author supports with many anatomical preparations, the hypophysis must be relegated to that class of glands having both external and internal secretions, which includes the majority of all glandular organs. The internal secretion gains the general circulation, while the external passes directly into the brain. It may, of course, be contended that, as these secretory tubules merely dis-

charge into lymphatic structures and can hardly be regarded as other than a part of the latter, the term external secretion must be employed with great reserve.

Genius and Stature.

Professor Arthur Keith of the Royal College of Surgical, England, has recently delivered himself of a pronouncement which seems not unlikely to get him into hot water. He stated a few weeks ago that "the small man is invariably the intellectual superior of the tall man." "Look," he says, "at all or nearly all of the prominent figures in the world's history. The great Cæsar was anything but a tall man, Napoleon was distinctly small, and so was Sir Isaac Newton. In our own day in the world of arms there is Lord Roberts, in the world of politics Mr. Lloyd George. In the last war the little Japs beat the big Russians. In all the evolutions of mechanical skill, little men as a rule have predominated." Leigh Hunt, in his autobiography, and others have said much the same thing as Keith. Of course, Keith's remarks called forth vigorous protests, and one writer avers that quite as many tall men, some of them, indeed, exceptionally tall, have displayed talent of the highest order as have little men. In the history of the United States, perhaps, a larger proportion of the most eminent men have been tall than small, Lincoln and Jackson, for example. But there is no agreement as to what constitutes a genius. A man of genius is undoubtedly a deviation from the normal; he is not as other men are. He may not be regarded by his fellowmen as in all respects sane and yet he may be possessed of the highest genius. Whereas, on the other hand, a man may be eminently rational and of the greatest talent and yet not be a genius. If a definition of genius could be selected upon which all would agree there would still be much difficulty in deciding if the quality had been more often present in the bodies of small men than in those of large men. That the little man often regards himself as a genius is a fact of common observation, and that he really is such more often than his two-yard brother is probably true.

Beriberi Among the Philippine Native Scouts.

During recent years American, British, and Japanese investigators in the Far East have paid close attention to the causation of beriberi and have generally concluded, as our Manila correspondent has repeatedly shown, that the disease is mainly due to highly milled or polished rice. In the *Military Surgeon*, May, 1911, Major Weston P. Chamberlin, Medical Corps, U. S. A., describes certain changes in the diet of the Philippine native scouts, with the result of diappearance of beriberi among the members of that body. The Board for the Study of Tropical Diseases as They Exist in the Philippine Islands, of which Major Chamberlain is president, has carefully observed the results of changes in the diet of the Philippine native scouts which have been made during the past year or more, and as a consequence still adheres to the polished rice theory of beriberi production. The real factors in the eradication of this disease from the scout organization have been a reduction in the amount of rice consumed and the addition of legumens. This result was accomplished without the use of undermilled rice, but it is the opinion of the board that the adoption of undermilled rice for the Philippine scouts will allow this grain to be used more freely by the soldiers with less risk of beriberi than would be the case if the polished article were supplied to them. Since rice is the natural and economical diet for the Oriental native, it follows that the free use of undermilled rice is likely to work in the direction of both efficiency and economy. The disappearance of beriberi among the scouts during the latter half of 1910, while at the same time the incidence of the disease among the general native population showed no decrease, must be more than a coincidence, and seems to prove that the disappearance was due to a change of diet, or perhaps to a more varied diet. Many of the natives will endeavor to subsist on rice alone no matter how varied or well-balanced a diet is provided, and therefore it is advisable to supply undermilled rice on account of its superior nutritive qualities, and of its apparent innocuousness so far as beriberi causation is concerned.

The Nervous Factor in Alopecia.

Not many years ago it was possible to write a long article or even a book on the subject of nervous and trophic factors in the causation of skin diseases despite inability to cite more than a beggarly number of actual documents to support the theoretical arguments. A connection, while suggested, could seldom to shown. This was especially the case with the nervous or trophic causal factors of baldness and canities. More recently something like convincing facts have been reported, in which definite nerves have been found to be in relation with the affected areas of the scalp. The nervous influence could be explained directly, as in neuritis of the occipital nerves, or indirectly through reflex influence acting upon the nerves. At a recent meeting of the Aerztlicher Verein, Munich (reported in the *Münchener medizinische Wochenschrift*, April 18), Trautmann reported a case of occipital alopecia following extraction of the supraorbital nerve. The connection between surgical intervention in the trigeminus field and occipital alopecia, numerous cases of which are on record (such as follow tooth drawing, operations on the frontal and ethmoidal sinuses, etc.), is obscure unless it can be set down to the credit of a special reflex. But at least it represents something definite. In the author's case the hair fell out *en masse* on the day following the operation, leaving the occiput nearly bare. Six weeks later there was evidence that the hair was growing in.

News of the Week.

Single Medical Examining Board for Pennsylvania.—Governor Tener has signed the one-board medical bill passed at the session of the Pennsylvania Legislature just closed. The new law provides for the establishment of a Bureau of Medical Education and Licensure, consisting of seven members, the superintendent of Public Instruction and the Commission of Health being members *ex officio* and the remaining five to be appointed by the Governor and to be selected from the three present legally incorporated medical societies of the State—one from the Medical Society of the State of Pennsylvania, one from the Homeopathic, and one from the Eclectic Society—who shall be licensed and qualified to practise under existing laws and shall have practised not less than ten years in the State; the two remaining members shall not both be of the same school or system of practice. No member of the

bureau shall be a member of the faculty of any school, college, or university teaching medicine or surgery. In addition to medical lincensure the board shall have the duty of ascertaining and reporting annually the character of the instruction given by each medical institution chartered in the State and its facilities for teaching the various departments of medicine in accordance with the standard required by the act. This comprises a general preliminary education of not less than a standard four years' high school course or its equivalent and a graded medical and surgical course of four years, each of which shall be not less than 35 hours each week of active work in didactic, laboratory, and clinical study in different calendar years. Any medical institution chartered by the State and empowered to grant the degree in medicine that shall be unanimously adjudged by the bureau as failing to maintain the required standard shall be duly notified, and failure to conform after notification shall render graduates of that institution ineligible for license. The bureau is further empowered to examine any persons pretending to a knowledge of a minor subject or subjects pertaining to medicine and surgery or semimedical and surgical subjects who have schools and colleges teaching such subjects, for the purpose of establishing regulation and State licensure. The bureau is to have the same kind of oversight over such schools as over medical schools, and it is to conduct such limited examinations as may be necessary to determine whether candidates have the requisite degree of knowledge of their subject and are otherwise worthy of State licensure. After a system of special licensure shall have been established it will be unlawful to practise in any of these special pursuits without a license, and the general provisions of the act become applicable to the special practitioner. The new act does not affect the practice of dentistry, pharmacy, and osteopathy, for each of which provision is made by existing laws.

Infant Mortality.—The New York Milk Committee recently issued a statement calling attention to the fact that the death from intestinal complaints among children under two years of age was almost one-third greater in New York from January 1 to May 14, 1911, than it was during the corresponding period of 1910. During these four and a half months of this year there were 947 such deaths, an increase of 238, the percentage of increase being 32.2. The continuation of such a rate of increase would mean a total of 1,800 more deaths during the year. A large part of these deaths are unquestionably due to the use of "loose" milk as infant food, since it has been found that only 5 per cent. of the babies who died in New York last year were breast fed. The Milk Committee is in favor of the passage of an ordinance grading milk along the lines proposed by Commissioner Lederle, and is also working for the establishment by the city of additional pure milk stations. The city at present conducts twelve such stations, while the Milk Committee is supporting thirty.

Health Exhibit.—The De Witt Clinton High School Health League, New York, is holding its first exhibit in the school building at Tenth avenue and Fifty-ninth street. The league has been in existence for only four months, but it now has 1,600 members. The exhibit, which the boys have prepared with the help of the Charity Organization Society, the American Association for the Conservation of Vision, and the National Study for the Study and Prevention of Tuberculosis, consists of diagrams, pictures, and illustrations showing how the eyes are injured by improper use, of charts showing the relative value of foods for growing boys, and of mottoes pointing the way to health. There is also a tuberculosis exhibit. An effort will be made to interest other high schools in the League by sending the exhibit on to them.

Plague and Smallpox at Amoy.—Fifty-four deaths from bubonic plague and seven from smallpox were reported in Amoy, China, for the fortnight ending on June 2.

Cholera in Venice?—Rumors of another outbreak of cholera in Italy are current, and in Vienna it is reported that over three hundred cases have occurred in Venice, and that the water supply is contaminated. The Venetian authorities recently denied that there were any cases of cholera in the city.

Isthmian Mosquito Plague.—The coincidence of a plague of mosquitos and of an increase in the number of cases of malaria caused some alarm in the Canal Zone recently. The Sanitary Department of the Canal Commission after investigation has reported, however, that the insects are of the usual Isthmian variety, not stegomyia, and so far as is known not disease carriers at all. The first rains of the season cause the eggs to hatch out in enormous quantities. The mosquitos are dark with white bands on the abdomen and legs, and are easily mistaken for the yellow fever variety.

Hebrew Ladies' Dispensary.—This new dispensary which is situated at 84 Cook street, Brooklyn, in one of the most congested portions of the Williamsburg district, will be opened on June 15. The medical board consists of Dr. W. W. Dreyer, *President;* Dr. D. A. Meiselas, *Secretary;* and Drs. S. Robbinovitz, J. M. Goldberg, Joseph Friedman, and A. M. Goffen.

Rabies Scare.—Reports of outbreaks of rabies in Geneva and Auburn, N. Y., have been received by the New York State Department of Agriculture, and are now being investigated with a view to placing the two places under quarantine if the conditions warrant such action. It is said that the outbreaks so far this year have been much less frequent than in years past.

Gifts to Charities.—By the will of the late William Whiting of Holyoke, Mass., the Holyoke City Hospital receives a bequest of $25,000.

St. Luke's Hospital, New York, receives a bequest of $10,000 by the will of the late Catherine E. Daly for the establishment of two beds in memory of her husband, Henry F. Daly. One bed is to be in the men's ward, one in the women's, and both are to be used for the benefit of "dramatic, minstrel, variety, or circus performers."

By the will of the late Mary E. Lambert of Philadelphia the Pennsylvania Hospital receives three houses situated at 809, 811, and 813 Spruce street, adjacent to the dispensary.

By the will of the late William C. Gilmore of Philadelphia the sum of $5,000 is bequeathed to the Philadelphia Home for Incurables and $2,000 to the Samaritan Hospital.

The Boston Floating Hospital, the Children's Hospital, and the Massachusetts Homeopathic Hospital of Boston, the New England Peabody Home for Crippled Children at Hyde Park, and the Convalescent Home of the Children's Hospital at Wel-

lesley Hills, all receive substantial bequests under the will of the late Mrs. Mehitable C. C. Wilson of Cambridge, Mass.

Death Rate in New York.—For the week ending May 27 there were 1,406 deaths in New York City, the rate being only 14.72 per thousand against 15.03 for the corresponding week in 1910. Of the total number of deaths 116 were the result of violence, and 183 were due to pneumonia, 152 to tuberculosis, 41 to diphtheria and croup, and 25 to scarlet fever. Among children under five years of age there were 407 deaths; and of the total 554 occurred in institutions and 571 in tenements.

Dead at 104.—Samuel Putnam, the oldest resident of Franklin County, Mass., died at his home in New Salem on May 29, aged 104 years. He was a direct descendent of Gen. Israel Putnam.

Milk Depots Open.—The summer milk depots maintained by Mr. Nathan Straus in New York were opened on June 3, about two weeks earlier than usual. Eight depots are open all the year around. At all of them pasteurized milk in nursing bottles is supplied at about half cost, and milk modified to suit babies at various ages is also supplied, as well as free medical advice.

New Hospital Site.—The Federation of Russian-Polish Hebrews of American has bought the entire block in Eighty-sixth street, between Henderson place and East End avenue, New York, for a new building for the Beth David Hospital, which is at present situated at 246-248 East Eighty-second street. The new site faces on the East River Park. It is planned to erect a six-story building, 90 feet long and 72 feet deep, with accommodations for 150 patients.

New York Homeopathic Medical College.—Fourteen students received diplomas from the New York Homeopathic Medical College and Flower Hospital on May 31, the graduation exercises being held in the auditorium of the Engineering Societies Building. At a meetng of the Alumni of the College held on the following evening, Comptroller Prendergast spoke of the plans which the city is making for the development of its hospitals.

Chief Medical Officer.—The New York Legislature has recently passed a bill amending the New York City charter so as to provide for the appointment of a chief medical officer of the Fire Department, at a salary not to exceed $6,000 a year. At present there are eleven medical officers in the Fire Department, all of equal rank. The measure does not become effective until signed by Mayor Gaynor, in which event the Board of Estimate will be called upon to appropriate the necessary money.

Dr. Allan McLane Hamilton was elected an honorary member of the American Neurological Association at the meeting held at Baltimore, Md., May 13, 1911.

Dr. Walter H. Connolly was appointed first deputy medical superintendent of Bellevue and Allied Hospitals, New York, at a meeting of the trustees held on May 31. Dr. Connolly, who is at present connected with the Department of Public Charities, was graduated from the Albany Medical College in 1891, and was later connected with Albany City Hospital and with the Buffalo State Hospital for the Insane.

Dr. George B. Young of the United States Public Health and Marine-Hospital Service, stationed at Chicago, has been granted a leave of absence from the Federal service in order that he may accept the post of Health Commissioner of Chicago.

Dr. Harry M. Archer, a surgeon in the Fire Department of New York City, was the guest of honor at a dinner given at Churchill's on June 1 by the deputy chiefs and battalion chiefs of the department. Dr. Archer was presented with a set of engrossed resolutions and with a kit of surgical instruments.

New Hospital Opened.—The new Minnesota State Hospital for the Criminal Insane at St. Peter was formally opened on May 23, fifteen patients from the hospital at Fergus Falls being transferred to it. The hospital has accommodations for sixty inmates.

Site for Medical College.—The Charleston, S. C., City Council has granted to the Medical College of South Carolina a fee simple to Lucas Park, which is city property, on which to erect a new building for the college. The structure is to cost not less $75,000 and must be completed within three years. The college will graduate forty-nine students in medicine this year and nineteen in pharmacy.

Medical College of Virginia.—The degree of doctor of medicine was bestowed on forty candidates at the annual commencement exercises of the college held in Richmond on May 31.

University of Nebraska Medical College.—Nine young men and one young woman received the degree of doctor of medicine at the annual commencement exercises of the college held in Omaha on May 18.

American Association of Genitourinary Surgeons.—At the 25th annual meeting of this association, held in New York City, May 31 to June 3, 1911, the following officers were elected for the ensuing year: *President,* Dr. Edward Martin of Philadelphia; *Vice-President,* Dr. Edward L. Keyes, Jr., of New York; *Secretary and Treasurer,* Dr. J. Bentley Squier of New York. *Members-of-Council,* Drs. Charles L. Gibson and Robert H. Greene of New York. Philadelphia was selected as the next place of meeting.

Wisconsin Homeopathic Medical Society.—At the forty-seventh annual convention held in Milwaukee on May 24, the following officers were elected: *President,* Dr. G. F. Adams of Kenosha; *Vice-President,* Dr. Minnie Hopkins of Oconto; *Secretary,* Dr. F. T. Clarke of Waupun; *Treasurer,* Dr. F. E. Brown of Milwaukee.

Wisconsin Medical Woman's Association.—The second annual meeting of this association was held in Milwaukee on May 23, when officers for the ensuing year were elected: *President,* Dr. Lucia C. Hoyer of Milwaukee; *Vice-President,* Dr. Luella Axtell of Marinette; *Secretary,* Dr. Minnie McClelland-Hopkins of Oconto; *Treasurer,* Dr. Anna P. Corr of Juneau.

American Society of Tropical Medicine.—The convention of this society held in New Orleans was concluded on May 19 by the election of the following officers for the ensuing year: *President,* Dr. Joseph H. White of the United States Public Health and Marine-Hospital Service; *Vice-Presidents,* Dr. Judson DeLand and Dr. Richard Strong; *Secretary,* Dr. John M. Swan; *Assistant Secretary,* Dr. Allen J. Smith; *Treasurer,* Dr. C. Lincoln Furbush. The next meeting of the society will be held at the same time and place as the meeting of the American Medical Association.

Missouri State Medical Association.—At the meeting of the society held in Kansas City on May 18, resolution was passed which will be presented to the next State Legislature, asking for an appropria-

tion to establish a full medical course at the Missouri State University. The present course is for only two years.

Portland County (Ore.) Medical Society.—At the annual meeting on May 17 the following officers were elected: *President,* Dr. William House; *Vice-President,* Dr. N. W. Jones; *Secretary,* Dr. George S. Whiteside; *Treasurer,* Dr. Katherine C. Mannion. Plans for the erection in Portland of a building for the use of the Portland City and County Medical Societies were discussed and subscriptions amounting to $14,950 were received.

Florida State Medical Association.—At the thirty-eighth annual session of this society held in Tallahassee on May 11 officers for the ensuing year were elected as follows: *President,* Dr. A. H. Freeman of Starke; *Vice-presidents,* Dr. J. B. Bennett of Crystal River and Dr. N. A. Baltzell of Marianna; *Secretary and Treasurer,* Dr. J. D. Fernandez of Jacksonville. Tampa was selected as the place for the next meeting in May, 1912.

Ohio State Medical Society.—The annual meeting of the society was held in Cleveland on May 9 and 10, when the following officers were elected for the ensuing year: *President,* Dr. Horace Bonner of Dayton; *Vice-presidents,* Dr. C. B. Parker of Cleveland; Dr. J. C. Larkin of Hillsburg; Dr. George Hickson of Cambridge; Dr. S. D. Foster of Toledo; *Secretary,* Dr. J. H. J. Upham of Columbus; *Treasurer,* Dr. Joseph A. Duncan of Toledo. The next meeting will be held in Dayton.

Kansas State Medical Society.—At the forty-fifth annual meeting of this society held on May 5 in Kansas City the following officers were elected for the ensuing year: *President,* Dr. J. T. Axtell of Newton; *Vice-presidents,* Dr. George M. Gray of Kansas City, Dr. H. G. Welch of Hutchinson, and Dr. Harry Anderson of Lincoln; *Secretary,* Dr. Charles S. Huffman of Columbus; *Treasurer,* Dr. W. H. Munn of Topeka. The society will meet in Hutchinson next May.

Care of the Child.—During the coming summer the Department of Health through the Division of Child Hygiene will make a steady effort to reduce the mortality of infants under one year of age. After June 15 the nurses now in attendance in the public schools will be withdrawn, and each nurse will be placed in charge of 150 babies in the more congested districts of the city where the birth rate and the death rate are both high. This work will be continued until the reopening of school in the fall. Already nine stations for the distribution of milk for children have been opened in the city, and four additional ones will be ready at an early date. The department will also establish lecture centers for conferences with mothers, with instruction in the care of well babies, in the prevention of disease and in the care of sick babies. These lectures will be given at the various recreation centers and piers, etc. During the last month of school also lectures on the care of babies will be given to all girls over twelve years of age.

Second District (North Carolina) Medical Society.—The organization of this newly formed society was perfected at a meeting held in New Bern recently, the following officers being elected: *President,* Dr. B. F. Taylor of Washington; *Vice-Presidents,* Dr. R. S. Primrose of New Bern, and Dr. W. H. Dixon of Ayden: *Secretary-Treasurer,* Dr. K. P. B. Bonner of Morehead City.

Lafayette County (Missouri) Medical Society.—At the annual meeting of the society held on May 11 the following officers were elected: *President,* Dr. T. C. Ryland of Lexington; *Vice-presidents,* Dr. H. Schrieman of Concordia and Dr. W. A. Braecklein of Higginsville; *Secretary and Treasurer,* Dr. H. B. Clayton of Odessa.

North Dakota Medical Association.—The annual meeting of the association was held in Fargo on May 9 and 10. Officers for the ensuing year were elected, as follows: *President,* Dr. C. E. Spicer of Litchville; *Vice-presidents,* Dr. F. J. Connell of Minot, Dr. M. McGregor of Fargo, and Dr. R. H. Beek of Lakota; *Secretary,* Dr. H. J. Rowe of Casselton; *Treasurer,* Dr. Frank J. King of St. Thomas.

Obituary Notes.—Dr. William Alfred Burgess of Cheyenne, Wyo., a graduate of the Medical Department of New York University in 1888, visiting surgeon to St. John's and the Cheyenne Private Hospitals, a member of the American Medical Association and the Association of Military Surgeons of the United States, and first vice-president of the Wisconsin State Medical Society, died at his home on May 15, aged 46 years.

Dr. Joseph J. Selbach of Eau Claire, Wis., a graduate of the College of Physicians and Surgeons of Chicago in 1888, and a member of the Wisconsin State and Eau Claire County Medical Societies, died at the Sacred Heart Hospital on May 25, aged 47 years.

Dr. Emma W. Mooers of Boston, Mass., a graduate of the Department of Medicine and Surgery, University of Michigan, curator of the neuropathological museum of the Harvard Medical School, and a member of the Massachusetts State and Suffolk County Medical Societies, died in the Massachusetts General Hospital from streptococcus infection contracted in the course of her work, on June 2, aged 52 years.

Correspondence.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

THE STATE INSURANCE SCHEME—PULSUS ALTERNANS—LIMITS TO VALUE OF SALICYLATES—VACCINE THERAPY—CHAIR OF LARYNGOLOGY—GENERAL MEDICAL COUNCIL—MEDICAL SOCIETY OF LONDON—OBITUARY.

London, May 19, 1911.

The State insurance scheme is not meeting with the support its authors expected from the profession. Already the Edinburgh College of Surgeons has passed a resolution that, in view of the important part which the medical profession must play in making any such scheme successful, and the serious consequences which may result to the profession as a whole, it ought not to be pressed forward in the present session. The propriety of spending money on sanatorium buildings has been mentioned in Parliament. Papers which support the government are in doubt on this matter, though it is generally thought that the Chancellor of the Exchequer will not reconsider a proposal which appeals so forcibly to sentiment. Many letters have been sent by doctors and others to M. P.'s urging them to insist on full discussion in the House, whatever delay may be thereby caused. Then the holders of ready-money practices, and dispensaries are mainly supported by non-club men, and look with no favor on the plan of administration through friendly societies. A deputation was introduced to the Chan-

cellor yesterday by Dr. Addison, M. P., and it is reported that the payment per head will not be limited to 4s., but may be taken as about 6s. It is not intended by the bill to make a separate class of State doctors, but that the insured should have the choice of their attendants. The profession need to be on its guard, lest once more it suffers. Fair warning was given by Mr. Lloyd George when he acknowledged that doctors deserved and would get something, but not all they asked for.

In his recent address at the Hunterian Society Dr. Davenport Windle, who last year took the Hunterian prize for his essay on "Heart Failure Associated with Pulsus Alternans and Abnormal Respiratory Rhythm," referred further to this subject in connection with angina pectoris. In many subjects of anginal attacks abnormal rhythm of breathing is very pronounced, and alternating pulse is frequently present. These disturbances have not been heretofore noticed as common—still less their relationships. Dr. Windle has carefully studied them and his observations on pulsus alternans tend to disperse the confusion that has prevailed concerning it. Clinically, the name has often been applied to any pulse beating with alternate force. This leads to errors in diagnosis and treatment. True pulsus alternans, he says, has definite characteristics; a strong beat is regularly followed by a weaker beat, and the intervals between the beats are equal in duration. At times a slight difference in the length of pause from pulse to pulse may be felt, but if so it is always slight, and the longer pause invariably follows the stronger beat. Numerous records showing this and other points were exhibited, as well as a number of lantern slides illustrating the various conditions described in the lecture. The regular rhythm of the true alternating pulse may persist for months, but sooner or later it becomes irregular from the occurrence of premature beats or extra-systoles. This may be difficult to detect unless a record tracing is taken. Exertion always makes the alternation more perceptible, and in an obscure case a tracing should be taken after a little exercise. In most cases the tension is high and the difference in force of the beats most easily felt by firm pressure of the artery, but if the pulse is of low tension the finger pressure should be as light as possible. Occasionally the weaker beat may fail to reach the wrist and it appears as if the pulse-rate had fallen to half, but on listening to the heart the contractions will be heard to take place regularly. There is a "pseudo-alternating" pulse, or "pulsus bigeminus." It results from extra-systole. It is very important in practice to distinguish this on account of the difference of its significance. The weaker beat occurs prematurely and is followed by a longer pause than that following the stronger beat—just the reverse of the true pulsus alternans. But to show this a tracing should always be taken, though the irregularity may often be felt by the finger. The pseudo-alternating pulse has no significance as a symptom, and the prognosis when it is present in a case must be made entirely from the clinical conditions. Perhaps it only means a little extra excitability of the heart. Although it is usually associated with cardiosclerosis, it is no index of the degree of degeneration, and gives no indication of the expectancy of life. Quite otherwise is the significance of true alternation, which indicates a high degree of degeneration of the heart muscle. Moreover, it is the expression of an exhausted heart. In patients with arterial disease, sooner or later this pulse will be accompanied by grave symptoms of heart failure; they may keep pretty well for a few months, but the outlook is unfavorable. The prognosis has not been systematically studied, and the only textbook on heart diseases in which it is referred to is Mackenzie's. Of Dr. Windle's seventeen cases none lived more than seventeen months after pulsus alternans was detected.

The successful use of the salicylates in rheumatic affections was brought before the Medical Society of London on the 8th inst. by Dr. A. E. Voelcker, in a paper which he devoted specially to the limitations which must be observed concerning them. He pointed out that, while some rheumatic affections responded rapidly to salicylates, others were uninfluenced by them. The most striking benefit was in joint pains. If these persisted after twenty-four hours' free use, the possibility of septic or other cause must be investigated. Pains about the fibrous structures often continued, but yielded to iodide and the oil of wintergreen, locally. Joint effusions, when aggravated by movements, were intractable to salicylates, even though they contained the diplococcus. The pyrexia of acute polyarticular rheumatism was generally controlled in three days, but the temperature was often high for weeks, without other symptoms. Such pyrexia might yield to salol or aspirin, though salicylates failed. In rheumatic hyperpyrexia pure salicylates were a waste of time. The skin manifestations of rheumatism were not influenced by the drug, which was also useless in chorea. In heart affections there was risk of upsetting the stomach by salicylates, also of acidosis. The object of the paper was by no means to belittle the value of the salicylates, but to show they were not specifics for every illness termed rheumatic.

Dr. de H. Hall agreed that not much good was done in chorea by salicylates, though they might be useful if the temperature ran high, even though there were no joint pains. Dr. Walter Carr asked how would these or other drugs do good to cardiac lesions, considering the impossibility of the heart resting? The incessant movement was against a good result. Dr. Paramore said smaller doses than those usually given yielded better results. Dr. Ewart combined iodide of potassium with the salicylate treatment. Dr. Parkinson said the relief of fever and pain in hospital practice led to patients being allowed to go out too soon and that led to an increase in the number of cases of heart disease after rheumatic fever.

Vaccine therapy does not seem to be making much progress, so far as extending its use among general practitioners. Perhaps this is better than any approach to a boom, for there is still work to be done, and we need further research as to the process and conditions of immunity. It is certain that some diseases of microbic origin are amenable to vaccines, and as our knowledge of infections improves we may anticipate better results. The bacteriologists are confident, if the practitioners are cautious. It is a disadvantage for the latter that they must get their vaccines from the laboratories in ampoules, dose for dose, as they cannot undertake the preparations of these remedies together with their clinical work. Then the subcutaneous administration is objected to by many patients; it has great advantages and is generally preferred, the dose can be exactly gauged, and if proper aseptic views are carried out it is free from risk. Intravenous injection has been tried a few times, but has been practically abandoned. The effect is rapid, but soon passes by,

excretion being rapid, and there is some risk. Oral administration has also been tried, and if it were better many practitioners would have resorted to it. The common conversation shows distrust, and, after all, the idea of swallowing the dead organisms or their toxins is not agreeable, and, further, the chemical changes continually proceeding in the alimentary canal must be reckoned with. Still, there are some who are experimenting in this way. Drs. Shenhouse, Williams, and Forsyth a month ago reported to the Liverpool Institute that they had given pneumococcus vaccine to guinea pigs in this and other ways. A dose which was surely fatal when injected into the peritoneum had no effect by the mouth, even if multiplied four or five times. It seemed a mere guess what possible effect might follow a dose. Dr. Rundle, however, thought he had been able to detect the effect of an overdose by symptoms like those of too large a dose subcutaneously. We can measure the dose and arrange the frequency of its administration, thus largely controlling the effect. But there are two points we cannot estimate or foresee, the reaction of the patient and the virulence of the organism. Dr. H. Pritchard, in a careful paper at the West London, considered these factors. As to the first, he said healthy people react differently to the diseased, and patients themselves differently under different circumstances. Close observance of well-known clinical signs is therefore necessary during the treatment. The virulence of the culture is also extremely variable, as much so as what we have seen in the infectiveness of disease taken in the usual way, *e.g.* typhoid, which may be very mild or most severe. Here again the variability of the patient comes in. The first culture is more virulent than subcultures, which suggests that where the full effect is desired primary cultures should be employed. It will be perceived that no definite rules can be laid down for vaccine therapy, but that every case must be carefully studied. Dr. Pritchard stated that generally the more virulent the infection and the more acute and grave the disease the smaller should be the dose. Even in chronic cases he deems it wiser to begin with a small dose. It is safe to give small doses at shorter intervals. Some acute cases could be vaccinated every day, or on alternate days. Chronic cases should be treated with small doses every third day and the interval increased up to seven or ten days, with increasing doses. After pointing out the cases most suitable for treatment by this method, Dr. Pritchard concluded that we are probably safe in expecting greater results, but more knowledge is necessary of the processes of immunity.

The University of London has accepted an offer of Sir F. Semon of a sum of £1,040 presented to him on his retirement from practice, toward founding a lectureship on laryngology.

The annual oration of the Medical Society of London was delivered on Monday by Dr. W. Pasteur, who took for his subject "Postoperative Lung Complications." The conversazione followed and was, as usual, successful.

Sir F. Champneys has been appointed a Crown member and Dr. J. A. Macdonald has been elected a direct representative to the General Medical Council.

Dr. C. C. Claremont of Portsmouth died on April 30, at the age of 56. He had been physician to the Royal Hospital, the South Hants Eye Infirmary, and held other appointments in Portsmouth since he settled there in 1880, holding at first a resident office. He was M.D. and B.S. of the London University, and much interested in science and literature, as well as his profession.

Mr. Robert Elliott, M.A., T.C.D. and L.R.C.S.I., who died on April 25, had been a medical missionary in India and subsequently in Palestine. He was invalided two or three times and had to retire from active mission work in the field. Eventually he became secretary of Church Society, Medical Missions.

The death occurred on the 14th inst. of Dr. Edward Bancks Whitcombe, aged 67, late Professor of Mental Diseases in the University of Birmingham. He had been medical superintendent of Birmingham City Asylum for the last thirty years. His father, grandfather, and great-grandfather were all doctors.

Dr. Edward B. Cornish Walker, late medical superintendent of the Hayward Health Asylum, died on May 14.

SANITATION IN AUSTRALIA.

(From Our Philippine Correspondent.)

ADELAIDE, AUSTRALIA, April 11, 1911.

THE Commonwealth of Australia dates from July 9, 1900, and is composed of the States of Queensland, New South Wales, Victoria, South Australia, West Australia, and Tasmania, which have a combined population at present estimated at 5,000,000.

In all of these states the various health functions were administered by a subordinate branch of the government, with the exception of Victoria, which has a Minister of Public Health and Commissioner of Public Works. Upon the organization of a federal government most of the powers relating to the public health were retained by the individual states. The exceptions to this general rule are maritime and interstate quarantine, marriage, vital statistics, invalid and old age pensions, the regulation of import, export, and interstate traffic in food and drugs and the medical inspection of arriving aliens.

With the exception of statistical matters the Commonwealth did not actually asume any of these functions until after the passage of the Quarantine Act in 1908.

In 1909 the quarantine service was organized under the Department of Trade and Customs. W. Perrin Norris, M.D., D.P.H., was appointed Director of Quarantine. The scheme of organization followed was practically the same as that now in operation in the United States, Canada, and Japan, which may be regarded as the highest development of this branch of public health work. The organization was carried out rapidly and an excellent system is in practical operation at all of the ports of entry throughout the Commonwealth. The facilities already possessed by the individual States were used wherever possible. The whole system is now being administered more economically and far more effectually than under State administration. At Sydney, just within the north head, there is a fully equipped quarantine station. The federal government is now spending considerable sums of money to enlarge and improve the plant. The station has a wharf at which vessels with deep draft may go alongside; a disinfecting plant, quarters for first and second-class passengers, and barracks for steerage pasengers and crews, power plant, laundry, and other essentials found in first-class quarantine stations. All vessels inspected

upon the northern or eastern coast which are found infected are remanded to the Sydney station for treatment.

Upon the southern coast there is a similar plant located about thirty miles from Melbourne and a smaller plant at Adelaide, which serve a similar purpose for the vessels found infected with quarantinable disease upon the southern coast. At Freemantle a modern quarantine station is now in course of erection and is intended to serve the western coast.

On account of the fact that plague has been introduced into Australia a number of times, and more particularly into Brisbane, Sydney, Melbourne, and Adelaide, all vessels from plague-infected ports must be fumigated to destroy rats and vermin. Dr. Norris, the Director of Quarantine, states that in their experience no agent for this purpose superior to sulphur dioxide has been found. There is considerable difference of opinion as to whether the "pot method" or the "furnace method" is the best for generating the sulphur gas. Recently some very successful experiments have been made with an improved Clayton furnace, by which it was demonstrated that the time required to fill a steamer was reduced one-half and the efficiency greatly increased.

For the destruction of flees, lice, bugs, or other insects or vermin a solution composed of equal parts of cyllin, soft soap, and kerosene is used by mopping or scrubbing or by forcibly spraying the mixture into all infested places.

Reinforced concrete wharves are the only form of rat-proof wharf construction which the Australian quarantine authorities recommend. Already a number of these have been built and it is the intention to make this type obligatory. In the meantime rat runs and other abiding places for rats have been obliterated in existing wharves. Ratbane is regularly used and bounties are paid for rats. The use of funnel rat guards on all lines leading to shore is strictly enforced, but not much success has been had in fending ships a safe distance from the wharves.

In 1909 the quarantine officers were also charged with making the medical examination of arriving aliens. These instructions provide for the detection of persons suffering from (a) an infectious or contagious disease of a loathsome or dangerous character, among which are included typhoid fever, diphtheria, demonstrable syphilis in an active communicable stage, gonorrhea, pulmonary or laryngeal tuberculosis, malignant malaria, uncinariasis, amebic dysentery, endemic hematuria, and trachoma. (b) Idiots or insane persons, and (c) persons likely owing to disease or physical or mental defect to become a charge upon the public. Among these are included feeblemindedness, epilepsy, blindness, deafmutism, severe hernia, heart disease, Bright's disease, chronic arthritis, paralysis agitans, paralysis, locomotor ataxia, senility, pernicious anemia, tuberculous affections (such as hip joint disease, Pott's disease and lupus), chronic alcoholism or its effects (such as cirrhosis of the liver).

In June, 1910, a set of uniform standards for food and drugs was formally agreed to by the principal health officers of the states composing the Commonwealth. This is in all respects very similar to that of the United States; the principal exceptions being that the British Pharmacopœia and the British Pharmaceutical Codex are used instead of the equivalent standard in the United States. A limited use of preservatives in food is also allowed. For instance 3½ grains of sulphur dioxide to the pound are allowed in mince meat, sausage, and saveloy sausage meat; 3/10 of one per cent of boric acid in butter and margarine. Traces of sulphur dioxide in dried fruit unavoidably remaining from the process of bleaching will not be questioned. Lime juice, lemon squash, and nonfermented drinks may contain not to exceed two parts per hundred proof spirit, or sulphur dioxide two grains to the pint, or salicylic acid two grains to the pint. Not more than one kind of preservative may be used in any one article and its presence must be declared upon the label.

The question of whiskey, which has given rise to so much controversy in the United States, is disposed of as follows: "Whiskey shall be spirit distilled wholly from barley malt by pot still or similar process, at a strength not exceeding 35 per cent. over proof, matured while subject to the control of the customs by storage in wood for a period not less than two years. Blended whiskey shall be spirit distilled partly from barley malt and partly from other grain, containing not less than 25 per cent. of pure barley malt spirit which has been separately distilled by a pot still or similar process, at a strength not exceeding 35 per cent. over proof, the whole matured while subject to the control of the customs by storage in wood for a period not less than two years." Spirits may be colored by means of caramel and sweetened by sugars. The declaration of the label of the caramel or flavor is not required.

In New South Wales a law has recently been passed which makes it illegal to publish misleading statements with regard to medicines or drugs in newspapers, handbills, bulletin boards, or otherwise. In brief, anything not allowed upon a label may not be made public otherwise. This law has already had one favorable court decision and offenders are now being actively apprehended.

Progress of Medical Science.

Boston Medical and Surgical Journal.

May 25, 1911.

The Occurrence of Infantile Paralysis in Massachusetts in 1910. Reported for the Massachusetts State Board of Health. R. W. Lovett and P. A. E. Sheppard.

Anterior Poliomyelitis. Attempts to Transmit the Disease to Monkeys by Inoculation with the Nasal, Pharyngeal, and Buccal Secretions of Eighteen Human Cases. M. J. Rosenau, P. A. E. Sheppard and H. L. Amoss.

An Experimental Study of Tendon Regeneration. J. W. Sever, M.D. Tendon Suture. F. L. Richardson.

Note on a Case of Paralysis Agitans and Cerebral Arteriosclerosis. W. P. Coues.

Poliomyelitis.—R. W. Lovett and P. A. E. Sheppard describe the epidemic of this disease that occurred in Massachusetts in 1910, involving 845 cases, as compared with 923 in 1909. A large epidemic center existed in Springfield. Forty-two histories of communicability were obtained in 200 cases.

Poliomyelitis.—M. J. Rosenau, P. A. E. Sheppard, and H. L. Amoss have not been able to demonstrate the virus of epidemic poliomyelitis in the buccal, nasal, and pharyngeal secretions of eighteen cases. They state that this is not proof that it may not have been there. In any event, the virus would have been greatly diluted, owing to the relatively large amount of salt solution used to wash the mucous membrane. Furthermore, under the conditions of the experiment, the virus may have been so attenuated as to be incapable of infecting monkeys. It is well known that a considerable quantity of the virus from the central nervous system of man is sometimes required to initiate the infection in monkeys. The authors'

results must not be construed as in any sense disproving the assumption that the infection in this disease may be discharged from the mucosa of the upper respiratory passage and enter through the same channel.

Tendon Regeneration.—J. W. Sever concludes that silk or linen thread is an excellent material to use to lengthen tendons in suitable cases. The growth of new tissue will penetrate and permeate the silk only slightly, and in some cases not at all, and does not absorb it. When the peritendineum and tendon sheath have been removed, some foreign body such as silk is essential for regeneration, to serve as a director for the new growth. With the sheath and the peritendineum present and sutured, no foreign body need be inserted. In this case the new growth is true tendon tissue. Without the presence of the sheath and the peritendineum no true tendon tissue can be regenerated. Such tissue is merely fibrous tissue, lacking elasticity and subject to stretching. The new "tendons" are apt to be larger and stronger than the resected ones, especially when silk has been used to replace the resected portion. Provided the sheath and peritendineum are preserved and function allowed early, adhesions may not occur. Without the sheath adhesions may and do occur much more frequently.

Tendon Suture.—F. L. Richardson states that the important things to be borne in mind in tendon suture, stated in the order of their importance, are: asepsis, preservation of peritendineum, approximation of ends, restoration of tendon sheath, and dryness of wound.

Paralysis Agitans.—W. P. Coues reports a case of this condition associated with arteriosclerosis in a male seventy-three years old. In addition to a tremor of the hands there was increasing mental impairment. There occurred sudden attacks of delirium, followed by complete unconsciousness, transient paralysis, and at times respiration as low as three or four to the minute. At different times there was absolutely no respiration for three-quarters of a minute. The patient recovered, except for the characteristic gait and the tremor.

A Plea for the Early Diagnosis and Early Surgical Treatment of Mammary Cancer with Special Reference to Obtaining Better Results. J. H. Gleason.

An Operation for Progressive Spinal Deformities.—R. A. Hibbs has devised an operation for the correction of spinal deformities as follows: A longitudinal incision was made directly over the processes; the ligament was split, and the periosteum of the processes removed very carefully and retracted with the muscles. The processes were divided at their base, as closely as possible, without opening the canal, then they were placed longitudinally so that there was fresh bone contact, one end, the proximal, touching the lower part of the fresh base from which the process was removed, and the distal end in contact with the upper part of the base from which the next process was removed, and so on throughout the diseased area, so as to ankylose the diseased one to healthy vertebræ above and below. The periosteum was then brought back and sutured with chromic catgut, and the skin closed with silk, without drainage. It seems that this method may possibly do much in the prevention of kyphotic curves and shorten the duration of the disease, saving the patient at the same time the necessity of wearing an apparatus for years. In the lateral curvatures it would seem to offer a means of preventing a progress of that distressing deformity.

Carcinoma of the Bladder.—G. E. Shoemaker reports a case of carcinoma of the bladder in which there occurred metastasis to the tarsus and metatarsus. The general rule that metastases follow the type of the primary lesion is well illustrated by the present case, where the occurrence of columnar types of epithelium in the bone and joint growth is contrasted with the types normally found in synovial membranes. Were there no other findings the tarsal tumor could be considered secondary from the microscopical examination. The introduction of the tumor cell by traumatism into the blood stream is more and more the dread of surgeons. The use of the tenaculum, the curette, and the excision of portions for diagnosis of cancer of the uterus is just as dangerous without the wide use of the actual cautery as is exploratory section of cancer of the breast.

Social and Sexual Hygiene.—C. E. Nammack believes that the study of sex hygiene should be taken up in the high schools.

Medical Nomenclature.—T. W. Schaefer makes a plea for a more accurate and modern scientific medical nomenclature.

Medicozoological Nomenclature.—C. A. Pfender states that the correct generic name of the protozoon which produces syphilis is *Treponema*, with *Treponema pallidum* as type species, and not *Spirochæta*, which has become popularized. The total inadequacy of the present methods for coping with the confusion in medical terms and the apparent insufficiency of the rules governing medicozoological nomenclature would indicate the necessity of some method of reform. A probable solution of the difficulty may lie in the appointment of a tribunal composed of recognized authorities in this branch of science from different parts of the world, to whom all names proposed must first be submitted for approval; the disposition of such name or names by this tribunal to be considered a final decree.

Lactic Ferments in Genitourinary Work.—F. S. Mason recommends the use of crayons containing cultures of the lactic acid bacteria in the treatment of gonorrhea in males, and of endometritis with or without gonorrheal infection and not primarily due to uterine displacements.

Methyl Alcohol Amblyopia.—T. B. Holloway reports a case of this condition and reviews the literature of the subject.

The X-Ray in Cancer.—S. Tousey states that it is the physician's duty to give the cancer patient the benefit of *x*-ray treatment from the beginning, instead of waiting until after a number of operations and the case has become inoperable and hopeless.

Mammary Cancer.—J. H. Gleason concludes that surgery, at the present time, presents the only means to cure cancer of the breast. The diagnosis of cancer must be made early, and the medical profession must insist upon an early operation. The earlier a cancer is operated on the greater the chance of cure. The laity must be taught that cancer in its early stages is a painless disease, and that every delay in submitting to operation lessens the chance of recovery. The dissection of Willy Meyer is the most scientific, the most radical and thorough, and presents a minimum opportunity only for the dissemination and implantation of cancer cells. The dermatoplastic modification of this operation by Jackson provides an ideal technique, free from many of the faults incident to the old curved and linear incisions. This modification also makes possible an early painless convalescence with little or no limitation in the functionating power of the arm.

Medical Education.—J. A. Witherspoon states that the Association of American Medical Colleges should adopt a uniform standard after consultation with all forces interested, and enforce this standard by frequent inspections of members. Inspections of both applicants and members should be placed in the hands of a judicial council or a committee appointed for the purpose; at least two men should be required for the inspection of any school, and the report should be in writing for future reference. The interests of the association demand that the work be divided up so as to utilize as many men and their influence as possible, if it would broaden its field of usefulness in both higher educational and moral or ethical standing sufficiently to make membership an honor so distinctive that all good schools will desire the connection. At present the four-year high-school, or the fourteen units for entrance and a four-year strictly graded course of study of 4,000 hours is as high as the conditions of education will permit. If an additional year is wise, then a fifth year following the present four-year plan, which shall be strictly practical and bedside in hospital wards, is preferable; and the association should insist that a hospital controlled by the college is essential to thorough training.

The Poisons of the Tropical Toad.—J. J. Abel and D. I. Macht have experimented with the milky secretion of the parotid gland of the tropical toad, *Bufo agua*, and have found it to contain two powerful substances. One of these, present to the extent of 7 per cent., is identical in its reactions and physiological effect with those of adrenalin. The other substance forms 36 per cent. of the secretion and is the digitalis-like substance for which the authors have proposed the name bufagin, as a short term sufficiently indicative of its origin. This substance is but slightly soluble in water, but can be obtained in whetstone-shaped crystals and prisms from an alcoholic solution. It consists only of the elements, carbon, hydrogen, and oxygen, with no nitrogen. It is easily soluble in chloroform and acetone, fairly so in absolute alcohol, and its melting point is 108° C. It is a neutral compound, insoluble in alkalies or acids, and in this respect resembles the bufonin isolated by Faust from the skin of the common toad. The authors, from their chemical studies, surmise that it is a depolymerized oxycholesterin. Its marked action on the heart, its vasoconstrictor action, and its powerfully stimulating action on the cardio-inhibitory center (an action completely annulled by section of the vagi and by atropin) compel them to class the drug with the most effective members of the digitalis series.

Laboratory Equipment and Instruction.—By E. P. Lyon. See MEDICAL RECORD, March 18, 1911, page 510.

Entrance Examinations.—By T. S. Fiske. See MEDICAL RECORD, March 18, 1911, page 510.

The St. Louis Hospital.—D. W. Montgomery describes the skin department of the St. Louis Hospital, Paris, which is one of the best of the kind that he has seen. It handles an immense amount of clinical material and its surgeons are among the foremost in the world in this specialty. He specially mentions the clinic of Sabouraud and his treatment of ringworm by the *x*-ray. This treatment has some disadvantages. The difficulty of treating ringworm of the scalp with the ordinary methods lies in the thick coating of stout hair in which the fungus lodges, but with the affected area completely denuded of hair by the *x*-ray the disease becomes as easy to treat as if on the free surface of the skin.

The Teaching of Visceral Anatomy.—J. S. Ferguson emphasizes the importance to the internist of an accurate and extensive familiarity with visceral anatomy.

The Hospital Year.—J. B. Herrick states that it is the privilege and duty of hospitals to open their wards more freely to undergraduates in medicine, to elevate the work done by nurses, internes, residents and attending staff, and to foster research. By so doing they do not harm the patient, but rather insure him better and more skilled treatment. The education would extend also to the observing lay public and would enlighten them on medical matters.

The Teaching Hospital.—W. M. Coplin states that the teaching hospital is most expensive to maintain. The expense of supplies is greater and the equipment necessarily more elaborate. The nursing force must be greater, as there must be nurses for a number of operating rooms and a nurse for each chief making rounds. The nurses are better trained in teaching hospitals, but complain of the increasing amount of work required. The larger number of operating rooms and the necessity of adapting the whole hospital régime to the needs of students to a certain extent instead of having the freedom in this respect of the unattached hospital is also felt as an objection.

The Micrograph.—By A. C. Crehore and F. S. Meara. See MEDICAL RECORD, May 27, 1911, page 983.

Pulsating Exophthalmos.—W. E. McClellan reports a case of this condition due to aneurysm of the internal carotid.

Excretion of Salicylic Acid and Hexamethylenamin in Sputum.—J. L. Armstrong and E. H. Goodman conclude that salicylic acid is excreted if at all in the sputum in such small quantities as to make its use in the diagnosis of pulmonary conditions useless. Hexamethylenamin, when given by the mouth is excreted in the sputum of tuberculosis, pneumonia, bronchitis, and asthma. There seems to be no selective action in the excretion of the drug and the detection of formaldehyde in the sputum cannot be used diagnostically.

Alcoholic Neuritis.—C. C. Wholey reports a case of this condition in a case of opium addiction.

Myasthenia Gravis.—F. W. Acker states that, although in this disease the prognosis as a rule is unfavorable, the patients living from one to two years, the following points in the treatment should be observed: All infections and toxic agents should be removed. The patient should take rest. Special attention should be paid to elimination. Tonics, such as strychnine and arsenic, should be administered. The diet should be of the highest concentration and easy of digestion, as the patient cannot chew and swallow well.

Exostoses of Auditory Meatus.—S. B. Muncaster recommends as an easy method of removing the hard exostoses of the external auditory canal the use of an extemporized notched toothed saw made of No. 1 snare wire or No. 1 piano wire.

Our Inability to Diagnose Gross Lesions of the Appendix. E. M. Corner.
A Case of Ovarian Cyst in a Nyasaland Woman. Hugh S. Stannus.

Postoperative Lung Complications.—W. Pasteur states that ether, *per se*, is probably not a direct cause of pumonary inflammation, and that respiratory troubles during anesthesia—whether due to faulty administration, unsuitable method, surgical manipulations, or the quality of the anesthetic itself—favor the aspiration of saliva, etc., into the lungs, and that in this way the anesthetic may become an important contributing cause of lung trouble. Postoperative lung complications occur with especial frequency after operations above the umbilicus. They are more likely to arise in septic cases, but are frequently associated with clean wounds. They usually develop within two days after operation, and are relatively uncommon after the fourth day. Complications arising after the first week are generally associated with septic processes. Most of the deaths occur in septic cases. The facts presented do not support the opinion that after-effects more frequently follow ether than chloroform anesthesia. Massive collapse of the lung plays an important part in the causation of postoperative complications. Deflation of the lung from whatever cause predisposes it to inflammation. Massive collapse may result either from paralysis of the diaphragm or the presence of acute inflammation or acute pain in the immediate neighborhood of the diaphragm. Massive collapse may closely simulate pneumonia. The conclusive sign of the former is displacement of the heart's apex beat toward the affected side and it is the only sign peculiar to the condition. In uncomplicated cases the symptoms tend to subside rapidly. The initial dyspnea rarely lasts more than a few hours, and by the end of the first 24 hours all urgent symptoms have usually cleared up. The displaced heart has already begun to move back toward its normal position, though this may not be fully regained for several days. It must be borne in mind, however, that collapsed lung is very liable to become inflamed, and where infective material is at hand the clinical picture of massive collapse may insensibly become replaced by that of bronchopneumonia. The author sums up tersely by stating that abdominal section is a bit below the belt. The patient is always winded by it more or less, and that is the real reason why abdominal operations are so often followed by lung trouble.

Mental Disorders and Suicide.—G. H. Savage states that every patient suffering from mental depression is a potential suicide, yet some patients are much more dangerous than others. The promise of a melancholic patient is not to be trusted, and the working of the insane mind is not to be judged by that of the normal one. It is well to recognize that most suicidal patients have their own special tendency—that is, they have a preference for one form of suicide rather than another. Some suicides are the result of impulses present markedly in the neurotic and in others who from age or illness have been reduced below their normal level of self-control. Many cases of suicide are to be attributed to insane impulses, due to acute alcoholism. There are instances of hereditary tendency to suicide. As regards special methods of suicide, it is noted that the tendency to jump from windows is especially attractive to women, while shooting and throat-cutting appeal to men. Suicide due to morbid egotism occurs in highly strung neurotics who are intolerant of suffering, whether the pain is physical or moral. In hypochondriacal patients with sexual ideas there is the greatest danger. A suicidal proclivity may follow bodily disease, chiefly influenza. "Altruistic" suicide may be the result of a martyr's ecstasy, leading the patient to long for death for the good of some one else. Suicide may be the result of a hallucination.

Radium Treatment of Cancer.—G. M. Moullin states that so far as our present knowledge is concerned, with the small quantities that we have at our command, radium can only be relied upon, and that to a limited extent, in cases of malignant disease in which growth is slow and the degree of malignancy relatively slight. On the other hand, it is of the greatest value in what may be called the premalignant stage—that is to say, in removing growths which not infrequently become malignant as age advances without an operation, and, what is very important, not merely for cosmetic but for clinical reasons, without leaving much of a scar; and there is good reason to hope that if the small quantities we possess now are capable of dealing with growths of relatively mild malignancy, larger amounts, when we can get them, will prove equally successful in circumstances of greater difficulty.

Radium Treatment of Cancer.—N. S. Finzi states that in cases which would otherwise be doomed complete local disappearance of the growth occurs in 12 per cent., relief of pain or other symptoms in 62 per cent., and no relief in 25 per cent. These statistics would be improved if cases were excluded which were treated for relief only. Every local inoperable growth of suitable type should be treated with radium. Prophylactic treatment should be used after every operation for cancer. Ten per cent. of successes means 90 per cent. ultimate failures or partial failures, and therefore no judgment can be formed in small numbers of cases as to final results. It is necessary to use large quantities of radium and metal filters at least 1½ mm. thick of lead or platinum. Since the author has used 205 mg. of radium in his later cases his results are showing promise of being very much better than when he used only 50 mg. Treatment must be thorough.

Diffuse Lipoma.—Sir Jonathan Hutchinson states that the well-known nuchal lipomata have their representatives in the pubic region. There are probably many examples of these, but patients will not be apt to disclose them.

Thrombosis of Superior Vena Cava and Great Veins.—T. C. Davies reports a case in which it is probable that the condition originated as a localized gummatous periphlebitis resulting in a spreading thrombosis of the superior cava and innominate veins. Moreover, it is probable that the antisyphilitic treatment employed cleared up the greater part of the gummatous infiltration, leaving untouched the fibrous tissue within the occluded vessels. The complex of symptoms was due to the thrombosis of the veins occasioned by the gummatous infiltration around. Antisyphilitic remedies could not remove the thrombus, and therefore the symptoms continued and the right heart dilatation progressed, eventually leading to a fatal termination.

Lesions of the Appendix.—E. M. Corner states that one cannot diagnose the slower, if milder, forms of appendicitis. The means at one's disposal are these: Take particular notice of abdominal pain in children, particularly when associated with discomfort in the right iliac fossa or without any ascertainable cause. In people of 35 years of age onward take particular notice of abdominal discomforts associated with general depression of health; as at that age the resisting power of the appendix—*e.g.* its lymphoid tissue, may be becoming inadequate for its needs. Remember that the operation of appendectomy in a quiet interval is absolutely safe, is easy, takes a short time, in modern surgery is without the risk of hernia, requires no abdominal belt to be worn after operation, and requires three weeks or less of convalescence.

Ovarian Cyst.—H. S. Stannus reports a case of mul-

tilocular ovarian cyst occurring in a Nyasaland woman. The liquid contents measured 33 pints and the weight of the whole tumor was 44½ pounds.

Observations on the Nature of the Immunity Reaction. C. J. Bond.
The Hulton Colliery Explosion. W. A. Hatton.
Two Cases of Severe Injury Near the Knee. R. Parker.
Vaginal Hysterectomy for Endometritis. F. P. Sturm.
A Case of Traumatic Pneumothorax and Pleural Effusion Successfully Treated by Resection. F. S. Rhodes.
Duodenal Obstruction as Shown by Radiography. A. C. Jordan.

The Immunity Reaction.—C. J. Bond states that there is some precedent for assuming as a working hypothesis a process of variation among the physiologically differentiated parts which compose the cell itself, together with a selection of the more favorable of the variations so occurring. The result of the examination into the conditions under which acquired immunity occurs tends to show that the process by which the defensive cells acquire new characters and new capacities of offense and defense is a process of variation and selection, partly of an intercellular and partly of an intracellular kind. It tends to suggest, in fact, that "use acquirement" is a form of adaptation to environmental change brought about by variation and selection among intracellular units instead of among individual cells.

The Hulton Colliery Explosion.—W. A. Hatton describes the medical aspect of the Hulton Colliery explosion that occurred December 21, 1910, with the loss of 343 lives. Carbon monoxide poisoning accounted for 287 deaths, or 81 per cent. The chief evidence of this poisoning was the dark carmine-red tinge of the skin. Poisoning by carbon monoxide is a very merciful death; there is no pain or distress; the person simply feels tired and sits down.

Two Cases of Severe Injury Near the Knee.—R. Parker describes the present condition of a patient, twenty years after the latter had been treated for hospital gangrene following an injury just above the left knee. He also reports a case of compound fracture of the femur, in which recovery occurred without defect.

Vaginal Hysterectomy for Endometritis.—F. P. Sturm states that there seems to be no reason why any woman, within sight of the menopause, who is suffering from such a distressing complaint as severe chronic endometritis, should retain an organ which is not only useless, but is even a constant menace to her health and existence, especially when that organ has already satisfactorily performed all the functions for which it was created. Vaginal hysterectomy by the double-clamp method is so safe, so simple, and can be so rapidly performed that the author sees no reason why it should not be the operation of election in cases of chronic endometritis which have failed to respond to more conservative and less effectual procedures.

Traumatic Pneumothorax.—F. S. Rhodes reports a case of traumatic injury to the lung, followed by pneumothorax and then pleural effusion, which recovered after resection of rib and drainage.

Radiography in Duodenal Obstruction.—A. C. Jordan furnishes the radiographic evidence of the condition described by W. Arbuthnot Lane as kinking at the duodenojejunal junction. The duodenal obstruction is of an intermittent nature. When present it may persist for several hours. It is frequently associated with obstruction at the lower end of the ileum or in the large intestine.

Berliner klinische Wochenschrift.

May 15, 1911.

Melanosis of the Mucosa of the Colon.—Pick concludes a serial article on this subject as follows: The affection is typical and limited sharply to the large bowel, extending from the ileocecal valve to the anus. Pigment is diffuse in arrangement, varying in shade from dark brown to the deepest black. Only the mucous coat is involved in the discoloration. As no inflammatory process is in evidence, the designation colitis pigmentosa is a misnomer. The epithelia are not involved, nor does the pigment migrate into the lymphnodes. The pigment is partly intercellular, partly intracellular; it is probable that at first it lies only within the cells, and appears between the latter only after disintegration of other cells. The pigment is always amorphous, never crystalline. In six cases tested for the purpose no metal was discoverable, and the pigment was undoubtedly true melanin, of endogenous source. The parent substances of the pigment are assumed to be indol, skatol, etc., converted by some oxidizing enzyme like tyrosinase. The condition is readily apparent during life in prolapsed rectum, showing clearly that it is not due to post-mortem change.

Inoculation of Apes with Syphilis Maligna.—According to Tomasczewski, the lesions of syphilis maligna in man are singularly free from spirochetes. Now and then patient study of serial sections may reveal the presence of a small number of the latter. A parallel between syphilis and tuberculous lupus in this regard is apparent. It is in syphilis maligna that salvarsan has shown its greatest power, and this remedy is believed to act through its spirillotropic power. In order to throw more light on the relationship of the spirochete to syphilis maligna, the author practised inoculation of apes with matter apparently free from the parasites. He is by no means the first to make this research, but others obtained more negative than positive results. In three cases he succeeded in inoculating each of his apes, the lesions appearing after prolonged incubation. The nodules thus set up were found to contain the spirochete, which must, of course, have been present in minimal numbers in the human tissues employed. It is selfevident that special malignancy cannot be conveyed in this manner.

Wassermann Reaction in Idiots, Epileptics, the Deaf and Dumb, and Blind.—Boas, Thomsen, and others of Copenhagen have instituted experiments of a sort already performed in England, the United States, and Germany in the hope of throwing some light on the etiology of these defective states. As was the case in the earlier experiments the results were practically negative, the percentage of positive findings being negligibly small, and agreeing in this respect with the figures recorded before the introduction of the Wassermann test. For the deaf and dumb and the blind the figures are so insignificant as to be remarkable—lower, if possible, than would be the case with controls. Idiots show less than 2 per cent. of positives and epileptics less than one-half of 1 per cent.

Recently Introduced Methods for the Treatment of Gonorrhea.—Hecht and Klausner consider in succession the Schindler treatment of acute urethral gonorrhea and the vaccine treatment of the complications. The former consists in the use of atropine, in daily doses up to 3 mgm., administered both in rectal suppository and by direct instillation. One c.c. of a 1:1000 atropine solution is introduced into a hollow suppository and this treatment may be continued for a long period without causing atropinism. If vision is interfered with the use of the drug is intermitted. In addition to atropine strong solutions of protargol (3 to 5 per cent.) are employed, cocaine being added to deaden the pain. The most claimed for this treatment by the authors is that in a number of cases the duration of treatment seems notably shortened. It is not stated as to whether the cases thus cured were first or subsequent attacks. In regard to the vaccine therapy of complications the authors are moderately enthusiastic, claiming that in certain cases of arthritis, etc., specific

positive results appear to be forthcoming. The failure in other cases, with inability to recognize in advance the conditions of failure, constitutes the greatest obstacle here, as with so many other alleged specific remedies.

Münchener medizinische Wochenschrift.

May 16, 1911.

Puerperal Sepsis After Normal, Spontaneous Birth.—Hofmeier states that in his twenty-two years' experience in the Würzburg obstetrical clinic, embracing nearly 13,000 confinements, he has seen but one instance of undoubted puerperal autoinfection. Patient was a primipara aged 17, who died of streptococcus septicemia on the eighth day after delivery. Expulsion of child and afterbirth had been spontaneous throughout. There had been one digital examination by a midwife, but infection from this source could readily be excluded, for at no time was there the least evidence of local genital infection, nor was there any peritonitis or in fact any localization whatever of symptoms. The patient died of acute general septicemia and hemolytic streptococci were recovered from the blood. The history of the case is no doubt calculated to clear up the mystery, the keynote of which seems to have been a cardiac arrhythmia developing very soon after labor. This persisted, and on the third day the pulse ran up rapidly to 150, temperature rose to 41° C., and apathy and somnolence gradually developed. Two years before the patient had been operated on for appendicitis and not quite successfuly, for she was confined to bed seven weeks, having high fever the while, with secondary pericarditis. Labor must have served to activate some of the streptococci, which were, perhaps, present in a latent or saprophytic state. The author has notes of a case somewhat similar to the preceding, which according to some authorities should be ranked under autoinfection, but gonorrhea was present and labor set up endometritis and peritonitis with fatal termination.

Etiology of Certain Mild States of Depression.—Dreyfus refers to mental states characterized by general out-of-sorts phenomena which affect the intellectual and emotional faculties. Patients cannot be diverted, cannot concentrate, weep readily, have groundless fears. Yet these conditions fluctuate in degree and depend evidently on some exogenic cause. There are no evidences in the personal or family history which suggest a psychopathic taint. There may be a failure of physical health antedating the mental component, characterized by failing appetite and nutrition, failing energy, insomnia, etc. This state of affairs is common in the fourth and fifth decades and suggests in men a sort of male climacteric, analogous to the same phenomenon in women at the menopause. After an interval of six months, or perhaps a year, equilibrium may return spontaneously. In another set of cases the condition is psychogenic in the sense of psychic causes acting on a normal pysche. Here belong psychic traumata in the widest sense of the term. Here belong the effects of physical injury when these result from the mental shock involved. While the patient's psyche is not tainted, it is still possible for the psyche to react to a combination of exogenic physical causes, such as overwork, underfeeding or under-nutrition, too brief sleep, etc. The patient is in a state of exhaustion, and requires only hygienic management. When the foregoing causal factors act upon a true psychopath his state of depression becomes confirmed. He becomes a pessimist, or a misanthrope, or with sufficient provocation develops manic-depressive insanity. The author wishes to differentiate all these depressive states from analogous conditions in hystericals, epileptics, arteriosclerotics, and others.

Death from Salvarsan in Subjects with Cardiovascular Disease.—Martins, representing Professor Ehrlich, analyzes the alleged material under this head, and after calling attention to the caution of his chief that salvarsan is contraindicated in such patients, especially when exhibited for parasyphilitic disease, states that but seven cases are on record in which there is any suspicion that salvarsan was responsible for death. Of this number five had aortitis, sclerosis of the coronaries, and myocarditis or myodegeneration, all due doubtless to syphilis. It is reiterated that such a combination of lesions absolutely contraindicates salvarsan. On the other hand, uncomplicated angina pectoris does not constitute a contraindication.

Deutsche medizinische Wochenschrift.

May 18, 1911.

Excretion of the Diastatic Enzymes by the Urine.—Rosenthal gives this subject monographic treatment, with following conclusions. Healthy men void a urine, the diastatic power of which varies at different periods of the day. The total daily urine, however, appears to contain a constant amount, corresponding in diastatic power to about 500 per cent. Any alteration or diminution in the permeability of the kidneys, such as occurs in diabetes insipidus and certain forms of chronic interstitial nephritis, may show a diminution in diastatic power. An increase in the renal permeability, such as occurs in acute infectious diseases, may cause an increase of enzyme content in the urine. If the urine has previously shown no diastatic power, the supervention of a disease of this type may cause the appearance of the same, to a degree corresponding to that of the healthy urine. In diabetes mellitus the diastatic power is usually, but not invariably, diminished.

Treatment of Hay Fever.—Hoffmann regards it as beyond question that this affection represents a supersensitiveness of the nasal and conjunctival mucosæ to the heterologous albumin which proceeds from the pollen of certain kinds of flowers. The reaction set up is of the vasodilator type. Predisposing factors are hyperthyroidism or some other form of disturbed equilibrium of the internal secretory mechanism. Leaving out of consideration the antidotal management the author proceeds at once to the symptomatic treatment. To offset the instability of the vasomotor nervous system as manifested by vasodilation he would use ergot and hydrastis as vasotonics. Calcium salts may be given two weeks before the calculated exposure to the pollen. The author gives no rationale in this connection, but doubtless expects the calcium to diminish the underlying reflex overexcitability. Of passing interest is the fact that large doses of alcoholics are believed to be able to blunt this abnormal excitability. Treatment directed to the supposed hyperthyroidism is purposely omitted. Next in order come the physical methods for promoting vasoconstriction, such as cold spraying, sound massage, and electricity. Cautery with trichloracetic acid or the galvanocautery may be indicated. The latter resource is recommended for prophylaxis.

Treatment of Pernicious Anemia.—Muktedir Effendi of Constantinople has placed on record a case of complete recovery from this affection under the use of a very commonplace remedy, to wit, glycerin. The blood count and general state were sufficient to establish the diagnosis, if considered jointly with the total failure of all customary remedies to arrest the disease. Glycerin was given, a dessertspoonful three times daily, for five months and the blood count slowly became normal, the patient meanwhile regaining perfect health. The author would not expect too much from glycerin in such cases, and would only employ it after the total failure of all other treatment. The rationale of the treatment is not stated, but the remedy was first given by Wieting on theoretical grounds, perhaps for its protein sparing property.

Book Reviews.

Manual of Diseases of Women. By W. E. Fothergill, M.A., B.Sc., M.D., Assistant Gynæcological Surgeon, Royal Infirmary and the St. Mary's Hospitals, Manchester; Clinical Lecturer on Obstetrics and Gynaecology in the Victoria University of Manchester. With 144 illustrations in the text. Price, $3.50. New York: William Wood & Company, 1910.

There are several novel features contained in this book which distinguish it from other works on the same topic. The writer departs from the usual manner of presentation by dividing his material into chapters which are based entirely on a pathological foundation. In the first portion of the book the diagnosis of gynecological cases is discussed in a brief but very satisfactory manner, and in the second portion the diseases of women are taken up under the following headings: Section I, errors of development, including congenital malformations and developmental errors at puberty. Section II, circulatory changes, including pelvic congestion, hematocele and hematoma. Section III includes mechanical conditions and injuries. In Section IV are described the results of infection. Section V includes progressive conditions (overgrowth and new growths), and Section VI describes retrogressive conditions, menopause changes, and superinvolution.

In discussing mechanical conditions and injuries, the writer presents certain ideas which vary with the usual ones on the subject of the treatment of prolapsed uterus. He prefers the operation of ventrofixation, fastening the uterus directly to the posterior fascia of the rectus muscle, and does not regard ventrosuspension or the various ligament operations of any value. Neither at this nor in any other place are detailed descriptions presented and there is also a lamentable lack of descriptive illustrations of operative procedures. In the treatment of retroversion and retroflexion, only one operation is described, in which the round ligaments are doubled up back of the uterus in the manner advocated by Baldy and others in this country. None of the other round ligament operations are favored. In the section on the results of infection the obstetrical aspects are carefully considered, and this is followed by the discussion of progressive and retrogressive conditions, in which are included the new growths. This portion of the subject is very adequately represented. The writer believes that the term endometritis should be dropped in the description of the condition to which it is ordinarily applied, as it necessarily implies inflammation, and that a more satisfactory substitute would be hyperplasia of the endometrium. The subject of fibroids is thoroughly discussed, especially as regards their relation to pregnancy. In the concluding portion of the book there is described the management of gynecological cases, including the local and operative treatment. The author does not seem to find much use for the medical or local treatment of this class of cases and wisely favors the restriction of the douche and tampons as ordinarily employed. He advocates limitation in the use of the pessary to a very narrow range of cases, but few will agree with the statement that these devices may be left in place for a period as long as three months without removal. In most respects Dr. Fothergill's book may be regarded as a brief but very satisfactory manual on the subject of the diseases of women. But it would seem that if intended for this purpose more attention might have been given to the description of operative details and treatment in individual conditions and their more satisfactory illustration.

Practical Physiology. Edited by M. S. Pembrey. Contributors: A. P. Beddard, M.A., M.D., Assistant Physician, late Demonstrator of Physiology Guy's Hospital; J. S. Edkins, M.A., M.B., Lecturer on Physiology St. Bartholomew's Hospital; Martin Flack, M.A., M.D., Demonstrator of Physiology London Hospital; Leonard Hill, M.B., F.R.S., Lecturer on Physiology London Hospital; J. J. R. Macleod, M.B., Professor of Physiology Western Reserve University, Cleveland, U. S. A.; M. S. Pembrey, M.A., M.D., Lecturer on Physiology Guy's Hospital. Illustrated by numerous diagrams and tracings. Third Edition. Price, $4.00 net. New York: Longmans, Green & Company.; London: Edward Arnold, 1910.

The third edition of this composite Practical Physiology will be welcomed by those teachers who need a convenient and compact guide to laboratory methods of physiology. The volume differs somewhat from the ordinary textbook in its very full treatment of the physiological chemical side, a subject which in this country is usually left to special treatises. This aspect of the question, however, is well covered and the methods are the most modern.

Le Tronc Cœliaque. Par Pierre Descomps, Prosecteur des hôpitaux. Travail de l'amphithéatre d'anatomie des hôpitaux. Recherches d'anatomie chirurgicale sur artères de l'abdomen. Price, 10 francs. Paris: G. Steinheil, éditeur, 1910.

There is still opportunity for a good deal of research on the percentage variations in the topography of the intestinal viscera and blood vessels. This monograph treats of the cœliac axis and its branches, furnishing numerous sketches of the unusual arrangements of the vessels with regard to the aorta and to viscera, which will prove of much value to the practical surgeon as showing him what are the relationships of this portion of the vascular system.

Publications of the Massachusetts General Hospital, Boston. Volume III, No. 2. October, 1910. Medical and Surgical Papers. Boston: The Barta Press, 1910.

The enviable scientific traditions of the Massachusetts General Hospital are to no small degree perpetuated by its well-known publications. The present volume is one of the most notable that has appeared, containing a large number of scientific papers of striking originality, most of which are reprinted from other journals. Among these articles the most important are two on the diagnosis of duodenal ulcer, by Cadman; a series of papers on the vaccine treatment of sepsis, gonorrheal arthritis, and urinary infection, by Hartwell and others; the surgical treatment of *x*-ray lesions, by Porter; renal tuberculosis, by Davis, and varicocele, by Barney.

Festschrift zur Vierzigjährigen Stiftungsfeier des Deutschen Hospitals. Herausgegeben von dem Medical Board un Auftrage der Aerzte des Deutschen Hospitals und Dispensary in der Stadt New York. New York: Lemcke & Buechner, 1909.

This volume is dedicated to the German Hospital of New York in commemoration of the recent celebration of the fortieth anniversary of its foundation. It is a typical *Festschrift* in every sense of the word, reflecting the manifold phases of scientific medicine which have been nurtured within the walls of the German Hospital by its small army of faithful workers. The opening contribution is from the pen of Jacobi, who discusses a subject that has been his favorite theme for many years, namely, infant feeding during the first half year of life. I. Adler contributes a masterly article on the diagnosis of primary malignant growths of the lungs and bronchi; Einhorn discusses newer experiences with the thread test in the diagnosis of gastric ulcer; Kaufmann details the management of hemorrhage in chronic gastric ulcer; Stadtmüller describes a case of erythremia; Kammerer contributes an article on unilateral hematogenous infections of the kidney; Kiliani reports two cases of spinal tumor successfully operated upon; Willy Meyer describes his recent improvements in the apparatus for the production of differential pressure in thoracic surgery. These are only a few of the many excellent contributions in this volume, which in its 593 pages represents a veritable mirror of modern medical and surgical progress. In elegance of illustration and typography and other mechanical features this volume is in keeping with the importance of the occasion which it commemorates.

A Textbook of General Bacteriology. By Edwin O. Jordan, Ph.D., Professor of Bacteriology in the University of Chicago and in Rush Medical College. Fully illustrated. Second edition, thoroughly revised. Price, $3.00. Philadelphia and London: W. B. Saunders Company, 1910.

The value of a treatise on bacteriology is to be measured largely upon the basis of its completeness and its inclusion of the latest investigations on the subject. Few branches of medicine have made such important strides during the past few years and there are few in which the older graduate is more compelled to add to his former store of knowledge. It is particularly for purposes of reference that a work on bacteriology appeals to the general practitioner. For these reasons one may recommend the present volume. The theoretical and the practical phases of the subject are fully presented. The chapters on immunity, the diphtheria bacillus, the colon-typhoid bacilli group, the tubercle bacillus with the related subjects of tuberculin diagnosis and therapy, and bovine tuberculosis, the pathogenic spirilla, and the pathogenic protozoa leave nothing to be desired. The industrial and agricultural aspects of bacteriology are fully dwelt upon. There is an appendix on the infectious diseases of unknown causation.

Society Reports.

ASSOCIATION OF AMERICAN PHYSICIANS.

Twenty-sixth Annual Meeting held in Atlantic City, N. J., May 9 and 10, 1911.

THE PRESIDENT, DR. FORCHHEIMER OF CINCINNATI, IN THE CHAIR.

(*Special Report to the* MEDICAL RECORD.)

First Day, Tuesday, May 9

The President's Address.—Dr. FORCHHEIMER of Cincinnati said that the best type of the country physician was also the best general practitioner in the country, and in the development of the general practitioner several things were to be considered, the man himself, his external surroundings, and his love for the same; he must have a good temperament and good judgment, and above all he should have a love for his calling. The proper man should have a genius for his work and should be willing to make personal sacrifices in carrying it on. He should have the greatest interest in his cases, but he should also have an interest in his patients as well. External conditions were relatively unimportant. Weeding out of the unfit was very quickly done in the medical profession. The doctors had to contend against poverty and professional competition, and often this was similar to the attempt to put a square peg in a round hole. Three important things to be considered were birth, the man, and his finances. It was only to the second of these that they all belonged. Success meant different things to different people. There were many who cared for external as well as internal success; many were satisfied with external success only.

With regard to the standards required by different States in medical education, of the eight States in which the highest preliminary requirements existed it was interesting to note that six of these were west of the Mississippi River. Some colleges required a man to possess his A.B. degree; this might mean much or it might mean nothing. One's preliminary education should be completed when a person was 18 or 19 years old. Students did not, as a rule, graduate until they were about 28 years old; he thought this was a bad state of affairs. The premedical and the medical course should be completed in eighteen years. The present status of medical education he considered to be very interesting. Many advances had been made. Thirty-five years ago no preliminary training was required, and the course each year was only about four months; students were given little or no laboratory teaching. They studied with a preceptor for three years. Dr. Forschheimer compared those days with the present. In the medical education of the general practitioner he considered three factors as important, the various authorities, the medical college, and the profession. The requirements of the different colleges differed in different States. The schools that attempted to teach too much should be shunned, as well as those which taught too little. Wrong was being done when the same requirements for obtaining a license were demanded from all parts of the country. In closing his address he took up the subject of the ultimate disappearance of the general practitioner, and he asked that they glance over with him the history of specialism. Especially in this country had specialism and specialists increased very rapidly.

A Clinical Study of Ascites.—Dr. RICHARD C. CABOT of Boston said that in his experience he had made a large number of wrong diagnoses of ascites in the service of Dr. Shattuck at the Massachusetts General Hospital, and he decided to make some investigations. One authority stated to him once, "The diagnosis of cirrhosis of the liver is a difficult diagnosis to make." Dr. Cabot always thought that such a diagnosis was an easy one, but since then he had reason to believe that this authority was correct in his assertion. For a basis for his work in the study of ascites he took the records of the hospital. Charts were shown. One chart showed the actual cases of ascites; that was, when there was a quart or more fluid in the peritoneal cavity which was not due to septic peritonitis or blood changes. There were tabulated 2,200 autopsies, but there was nothing striking about these cases or the results. Heading the list of causes appeared cardiac weakness; then the various neoplasms; then the renal cases; then cirrhosis of the liver; then tuberculous peritonitis; then adherent pericardium; then eclampsia, etc. The second chart was a clinical one and represented cases covering forty years of records. The figures did not differ materially from those given in chart 1. There were, however, a large number of cases of intestinal obstruction which Dr. Cabot thought had not sufficiently been emphasized as a cause of ascites. The third chart showed the rapidity of the accumulation of ascitic fluid. The two most important facts brought out here were the slowness of the accumulation in tuberculous peritonitis and the quick accumulation in the cardiac cases.

Dr. LEWIS A. CONNER of New York asked if in this work Dr. Cabot had ever used a study of the fluid itself to aid him in his diagnosis of ascites.

Dr. CABOT replied that he had used such tests and was convinced of their fallibility, especially when one studied the really doubtful cases.

The Present Status of the Tuberculin Test.—Dr. LAWRASON BROWN of Saranac Lake considered the specificity of tuberculin, its dangers, and the local reaction in the lungs, and closed by speaking of the value of this agent. From various figures given they knew that tuberculosis occurred in a large number of people, and the tuberculin test really showed instances of this disease. Little weight could be attached to the statement that tuberculin might cause a return of the tubercle bacilli in the sputum. Tuberculin should be accepted as a diagnostic aid in tuberculosis. The danger of giving it was slight. An increase in the physical signs occurred in about one-third of all the cases. The test was uncertain unless the pulmonary signs were increased during the reaction.

Dr. FREDERICK C. SHATTUCK of Boston believed that the use of the subcutaneous injections of tuberculin for diagnostic purposes did little, if any, harm. For many years he had used this method with great freedom, and in only one case did he get any untoward results. This had happened in a case of Addison's disease; it terminated fatally.

Dr. THEODORE C. JANEWAY of New York wished to corroborate what Dr. Shattuck had stated; he also had had a fatal case in a patient afflicted with Addison's disease.

Dr. HENRY KOPLIK of New York referred to an unpleasant experience that he had had with the v. Pirquet test with the old tuberculin. In older children the results obtained were similar to those obtained in adults.

Dr. ADLER of New York said that for two years he had had under observation a case of undoubted Addison's disease. This patient had been successfully treated with tuberculin injection, beginning with small doses and gradually increasing to larger ones. To-day the patient was clinically well.

Dr. JOSEPH L. MILLER of Chicago believed that in the use of the v. Pirquet test, even in the simplified form, much harm was done to patients by assuming too much; they often were sent away from home and their friends because of the positive results obtained; as a matter of fact there were no clinical evidences of tuberculosis at all.

Dr. BROWN said that it was his belief that when patients reacted to the tuberculin test they were afflicted with tuberculosis.

Note on the Favorable Influence of Quinine and Urea Hydrochloride Given Hypodermically in Large Doses in the Treatment of Acute Lobar and Lobular Pneumonia.—Dr. Solomon Solis Cohen of Philadelphia read this paper, in which he referred to the long-standing tradition that quinine given early would abort an attack of lobar pneumonia. An early experience of the writer's is cited, in which 60 grains of quinine sulphate given in error in a period of six hours, beginning two hours after the initial chill, apparently acted in this manner. The revival of the quinine treatment of pneumonia by Galbraith (1904) led the writer to employ it at the Philadelphia General Hospital and the Hospital of Jefferson Medical College; soon, however, substituting hypodermic for gastric administration and choosing the most active salt of quinine—namely, the double hydrochloride of quinine and urea, with which he had had such favorable experience in the tretament of malaria. From 6 to 10 grams (90 to 150 grains), according to effect, were given in from 48 to 72 hours. Cinchonism did not develop. Temperature and pulse fell gradually and proportionately, and respiration more rapidly—with a tendency to restoration of the normal pulse-respiration ratio. Blood-pressure remained stationary or increased; cough diminished, breathing became relatively easy; delirium abated or disappeared. Crisis did not occur. Termination was by lysis at about the ordinary time, 5 to 11 days. Percussion and auscultation signs were uninfluenced. Involvement of new areas might take place during treatment, with return of symptoms, necessitating new injections. Pneumococcic empyema had occurred. The pathological processes in the lung would thus appear to evolve in the customary manner, unmodified by the treatment, which was apparently not germicidal and was without effect on tissue changes. Since the most striking results were the relief of respiration and the maintenance of normal cardiac vigor and blood pressure, it seemed logical to infer that the effect was chemical and antitoxic. This view was further borne out by the absence of quinine intoxication, suggesting a mutual neutralization of disease poison and drug. Experimental observations on this point were desirable. Fresh air, water, saline infusions, and symptomatic medication when needed, were associated with the quinine treatment. The mortality in cases of patients under 50 years of age, admitted before the third day of the disease, was *nil*. Excluding alcoholic subjects transferred from the "drunk" ward, and senile patients transferred from the "out-wards," the general mortality was somewhat less than 10 per cent. Including all cases, even the alcoholics, the senile, the cases of terminal infection—that is to say the general class of unfavorable subjects met with at the Philadelphia General Hospital, where the expected mortality in various years ranged from 25 to 50 per cent.—the total mortality was a shade less than 20 per cent. Even in fatal cases the comfort afforded was marked, and no untoward symptom attributable to the drug had been observed.

Dr. Frederick P. Henry of Philadelphia said that he had used this method before Galbraith in 1904, and even before Dr. Cohen, but he used hydrochlorososulphate of quinine and not the double salt, and he did not use it in such large doses.

Dr. Jacobi said that he had used this preparation a great deal in the strength of 1-4. In both the living and at autopsy he had been able to find the quinine deposited in the tissues, the water being absorbed. He used this method for several years, but gave it up because of some bad results he obtained.

Dr. Cohen said he had not heard of Dr. Henry's use of this agent and therefore gave him credit for priority in its use. To be successful in its use certain things were of the utmost importance. The skin should first be painted with iodine; the injections should be deep, preferably intramuscular; they should not allow, on withdrawal of the needle, any of the agent to come in contact with the skin. The treatment was by no means a specific in cases of pneumonia; it was only an additional measure that could be used, but not indiscriminately. Dr. Cohen said he would not like to be called upon to treat these cases without having this important resource at hand.

A Pneumatographic Study of the Respiratory Irregularities in Meningitis.—Drs. Lewis A. Conner and Ralph G. Stillman of New York presented this paper. Forty-one cases of meningitis were studied graphically by means of the Maney spiral spring type of pneumatograph; one tube being placed about the upper part of the chest to record the thoracic movements, and a second about the abdomen at a point midway between the ensiform cartilage and the umbilicus to register the movements of the diaphragm. The cases included 19 infants, 11 children over two years of age, and 11 adults. There were 30 cases of tuberculous meningitis, 6 of the cerebrospinal type, 4 of secondary streptococcus meningitis, and 1 case of acute syphilitic, basilar meningitis. In all of the 30 cases of tuberculous meningitis respiratory disturbances occurred during some part of the illness and usually throughout the greater part of it. Among the 11 non-tuberculous cases alterations in the respiratory rhythm were observed in all but two cases. The disturbances of respiratory rhythm in meningitis could be divided into 3 fairly distinct groups: 1. Type of Cheyne-Stokes. 2. Biot's "meningitic rhythm." 3. An undulatory type. The Cheyne-Stokes type seen in infants and children with meningitis showed certain differences from that ordinarily seen in adults. Biot's type of breathing was characterized by constant irregularities in rate and force, by the frequent occurrence of deep sighs and by apneic pauses varying in length and occurring at irregular intervals. In the undulatory type there was a rhythmical variation in the force of the respirations, or in the tone of the respiratory muscles or in both of these together, without any periods of apnea. This undulatory type was observed at some time in almost every case. In 12 of the 41 cases it was the only type of disturbance noticed. In 23 cases (56 per cent.) Cheyne-Stokes breathing was observed. In 10 cases (25 per cent.) Biot's type was noticed at some time. In 6 cases both the Cheyne-Stokes and the Biot types were seen at different times. The disturbance of respiratory rhythm, in two instances, was noticed as early as the second day of illness, and in a number of other instances was seen by the end of the first week. It sometimes was present throughout almost the whole course of the disease; in two other cases it could be seen only occasionally or even only for a single day. Because of its occurrence in almost every case of meningitis and because it was often observed early in the disease this symptom of disturbed respiratory rhythm was of very considerable diagnostic importance, especially in meningitis of the tuberculous type in which the onset was often slow and insidious.

Abdominal Tenderness with Pain Due to Thoracic Lesions.—Dr. Arthur R. Edwards of Chicago read a paper which treated of thoracic disease with abdominal pain, reflected from the thorax to the abdomen. This was by no means an uncommon occurrence. He reported some cases with tenderness, with even rigid abdomen, simulating intestinal perforation.

Dr. J. P. Crozier Griffith of Philadelphia recalled a case which he had slipped up on in 1896; he said that he had slipped up in many diagnoses since. There were many diagnostic signs that were not to be at all depended upon. He had seen patients whom he thought had abdominal trouble but which turned out to be thoracic in nature. He cautioned all to be very sure of their diagnosis in these cases before advising operation.

Dr. Francis P. Kinnicutt of New York said that all

present must be familiar with the mistakes their surgical colleagues made in operating upon patients with supposed abdominal conditions, such as an appendicitis, when in truth they had thoracic troubles. There was one group of cases in which the primary trouble was a pleurisy or a pneumonia and in which the principal symptoms were referred to the lower part of the abdomen; in such cases the distribution of the intercostal nerves should be carefully studied. The symptoms in these cases were of an acute abdominal trouble and were very misleading. There was another group of cases in which the symptoms were confined to the upper portion of the abdomen; the abdominal pleura appeared to be involved. In many of these cases it would be wise to wait for some information that might be obtained from a blood examination.

Dr. Williams of Boston called attention to the fluoroscopic examination of the chest by which they could get evidence of disease even before the development of physical signs.

Dr. M. Howard Fussell of Philadelphia said he never approached patients who appeared to have abdominal troubles without some trepidation because of the mistakes he had himself made as well as because of those of others. He reported a case of a man, twenty-seven years old, a very hard drinker. He was seized suddenly with extreme pain in the right lower lumbar region; morphine had no effect apparently upon it. A few hours after he first saw him the abdomen was as tense as any he ever had seen. But there were present peristalsis and local tenderness. He had great difficulty in breathing, was cyanotic and in a state of collapse. His pulse was 120 and respiration 50. A very careful examination of the chest, however, revealed an area of dullness at the right base and this was finally decided to be a chest case and not an abdominal one. By subsequent events this was found to be correct. It seemed to him that there was no one symptom, or set of symptoms in fact, upon which one should make an absolute diagnosis.

Dr. James Tyson of Philadelphia went to the defense of the surgeon and recalled a case in which it was the surgeon that asked for delay.

Dr. S. J. Meltzer of New York said that he had seen a patient suffering from angina pectoris and treated by some of the best men in New York for gastric trouble and for gallstones. It should be remembered that the pneumogastric nerve supplied both thoracic and abdominal organs. He referred to a simple experiment. If one had some trouble in the teeth of the lower maxilla, say of the left side, and if the nasal cavity of the right side was slightly stimulated, severe pain would be felt on the left side. This was an instance of irradiation, or irradiated pain.

Dr. E. Libman of New York said that the abdominal symptoms in cases of intrathoracic disease were probably to be explained in a number of ways. In some cases they were symptoms due to irradiation along the lower intercostal nerves; in others, the abdominal symptoms (pain, hyperalgesia, tenderness of the muscles) were to be explained according to the ideas of Mackenzie, that the impulses were carried to the cord by sympathetic fibres, and then carried along the cerebrospinal nerves to the periphery. If there was a marked irradiation in the cord, the peripheral area involved might be quite extensive. In some cases Dr. Libman had found marked abdominal symptoms, especially in the right upper quadrant, which were to be attributed to an acute enlargement of the liver, with stretching of the peritoneal covering. This swelling of the liver caused a marked pain and tenderness of the abdominal muscular wall over the liver, sometimes over a wider area, together with rigidity and hyperalgesia of the skin. This swelling was at times to be explained by an acute congestion of the liver due to an insufficiency of the right heart.

Conjugal Tabes Dorsalis.—Dr. Augustus A. Eshner of Philadelphia said that syphilis was a very common disease and that it was the most important, if not the essential, cause of tabes dorsalis and of paretic dementia. Tabes and paresis might be considered expressions of the same morbid process, in the one instance affecting the spinal cord, in the other the brain. Sometimes they occurred together in the same patient. The disparity in the incidence of the two affections might be due to individual predisposition, or to some peculiarity of the syphilitic virus. Negroes rarely, if ever, developed tabes, though they were frequently syphilitic. Perhaps they possessed some racial immunity. Sometimes several members of the family developed tabes or paresis, sometimes husband and wife, sometimes in addition a second husband or wife, sometimes one or both parents together with one or more children. The association was not common, although probably more so than was apparent, as inquiry was not, as a rule, directed toward this point. When husband and wife suffered, the former was generally attacked first, the latter subsequently. A moderate number of cases had been reported in the literature. Dr. Eshner reported two cases of conjugal tabes dorsalis. In one the symptoms appeared in the husband and wife at about the same time. No history of syphilis was elicited, although infection might have occurred. In the second case it was learned incidentally that the husband of a woman who was under treatment for tabes likewise presented symptoms of the same disease, although he insisted that there was nothing wrong with him and declined treatment; he gave a history of an initial lesion.

Acute Dilatation of the Stomach as a Complication of Pneumonia.—Dr. M. Howard Fussell of Philadelphia reported four cases of acute dilatation of the stomach as a complication or early sequel of pneumonia. A review of the literature of this condition was made.

Comparative Toxicity of Various Alcoholic Beverages.—Dr. Julius Friedenwald of Baltimore read this paper. He said that these experiments were performed as an addition to the work, "On the Effect of Alcohol on Rabbits," published from the Pathological Laboratory of the Johns Hopkins Hospital some years ago. The plan followed was that introduced by Daremberg, *i. e.*, the intravenous injection of the alcohol diluted to less than 40 per cent., thus avoiding the danger of the production of emboli. Rabbits were utilized weighing two kilograms; the injections were made into the ear veins. Various brands of whiskey, brandy, and other alcoholic beverages were utilized. In order to compare the results obtained the alcoholic content of the drink was reduced to 38 per cent., and when the percentage of alcohol was low to 10 per cent. or even 5 per cent. It was demonstrated that pure alcohol is less toxic than inferior whiskey, and good whiskey less toxic than inferior whiskey, but more toxic than pure alcohol. Brandy was observed to be more toxic than alcohol or whiskey, and genuine brandy just as toxic as ordinary brandy. Rum was shown to be more toxic than alcohol, whiskey, or brandy, and gin more toxic than pure alcohol. Liqueurs run more toxic than pure alcohol, whiskey, or brandy, and just as toxic as rum. Beer was but slightly more toxic than pure alcohol, and ale was no more toxic than beer, but more toxic than pure alcohol. Wine was more toxic than alcohol or whiskey, and red wines were more toxic than white wines.

Two Cases of Acute Leukemia.—Dr. Henry Jackson of Boston reported these cases.

Case I. *Acute Lymphatic Leukemia.*—This patient was a man, twenty-one years old. In September, 1910, he had a swelling about his tooth. The tooth was extracted. In December he was very weak, very pale, and his gums were enormously swollen. The white blood count was 19,400, the red cells numbered 3,496,000, and the lymphocytes were 99.5 per cent. He gradually failed and died of exhaustion.

Case II. *Acute Myelogenous Leukemia of an Abnormal Type.*—This patient was a man thirty-four years old. He had swelling of the submaxillary glands which was soon followed by swelling of the cervical glands and gums. The gums became very tender and bled freely. His chief complaint was weakness. When seen he was markedly anemic and his gums were enormously swollen. The white corpuscles numbered 161,600, and the red cells 2,408,300. The white cells showed a predominance of abnormal myelocytes. Death occurred about one month after he was first seen.

The two cases were of special interest in that the chief symptom in each case was due to disease localized in the gums. The gums were very much thickened; along the edges there were superficial ulcerations, and they bled easily when touched. Both cases were considered as some local disturbance of the gums and mouth until the blood examination made the diagnosis possible. As the gums were generally swollen before a dentist was consulted as to the trouble, it seemed probable that the ulceration about a tooth was not the source of infection causative of the disease. The spleen was barely palpable in these cases.

Dr. Richard C. Cabot of Boston said that it seemed to him that more difficulties arose as the years went by in getting a clear demarcation between the clinical pictures of acute lymphatic leukemia, that was from a clinical point of view. He had seen three or four examples in which the diagnosis was made of septic infectious leucocytosis; in these the leucocyte count was 20,000 or 30,000 with a large percentage of lymphocytes, about 80 per cent. Yet there occurred a complete recovery and a lasting one.

Dr. Henry Koplik of New York reported the case of a child who was sent to the surgical ward because of a supposed osteomyelitis. The child was found to be suffering from acute lymphatic leukemia.

Report of a Case of So-Called Leukanemia.—Dr. William F. Hamilton of Montreal gave a brief statement of the blood picture in a case of anemia, with leucocytes like those of leukemia, the number not exceeding 8,000. There was an enormous increase in the size of the abdomen, evidently due to the size of the spleen. When he first saw the patient he made a hurried examination of the blood unfixed and he decided that there was no leucocytosis. The differential count was made later, and the original impression that there was no leucocytosis was confirmed. In fact the number of leucocytes did not exceed 7,000. The differential count showed the polymorphonuclears to be greatly diminished while the lymphocytes and large uninuclears were increased. There were a large number of nucleated red cells; the mast cells were from 1 to 1.3. Morphologically the case showed marked pathological changes. The term "leukanemia" he thought should be discarded.

The Possible Prevention of Pneumococcus Empyema by Urotropin.—Dr. Frederick C. Shattuck of Boston made a preliminary report on an attempt to determine whether the use of this drug prevented the development of empyema. Experiments were made at the Massachusetts General Hospital, at the Presbyterian Hospital, and at the Johns Hopkins Hospital. These experiments showed that urotropin did not prevent empyema in cases of pneumonia.

Bradycardia.—Dr. William S. Thayer of Baltimore presented notes of three such cases of different types.

Edebohls' Operation in the Treatment of Chronic Bright's Disease.—Dr. James Tyson of Philadelphia reported three cases in which the operation was done, one patient surviving seven years after the operation, and another patient still surviving one year after operation. He believed that this operation had a place in the treatment of chronic nephritis, not as a cure, but in saving and prolonging life. This paper will appear later in the Medical Record.

The Treatment of Chronic Nephritis in Children by the Edebohls' Operation.—Dr. Henry Koplik of New York said that the number of cases so far reported as being operated upon by this method was limited. The operation by no means was intended to be curative, but it was undertaken only in cases in which relief from the symptoms of nephritis had failed after all other means, medical and dietetic, had been tried. The operation itself did not necessarily endanger life. The improvement after the operation had been striking in spite of the persistence of urinary signs of marked disease of the kidney. The freedom from symptoms was combined with a status of well being in some cases for a period of years. Exposure or indiscretion would not exempt the operated case from recurrence of edema and other symptoms, but the patients, as in one of the cases reported, recovered promptly and remained well for a time, showing that the operation had not crippled the recuperative powers of the kidney.

Dr. George L. Peabody of New York said that he had had a large number of these patients operated upon and he would like to speak of one case in particular. This patient had had four operations performed in about two years. There recurred the symptoms described, the marked anasarca, eyes almost closed, etc. In each instance the result of the operation was an improvement which was very marked and which lasted for a few months and then the symptoms would recur.

Fever, Its Nature and Significance.—Drs. Victor C. Vaughan, James G. Cumming, and John H. Wright of Ann Arbor, Mich., presented this communication. In August, 1909, they published a preliminary article upon the subject of protein fever. In that paper it was shown that continued fever with charts closely simulating those of typhoid fever can be induced in rabbits by repeated subcutaneous injections of egg-white and certain other proteins; this work had been continued, and it had been demonstrated that by varying the dose and the intervals between doses one could induce an acute, an intermittent, a remittent, or a continued fever in rabbits by injections of foreign protein. Furthermore, it had been shown that by repeated intra-abdominal injections of various bacteria, acute fever, followed by immunity, would be produced. The authors would hold that fever resulted from the parenteral digestion of proteins, and that fever must be regarded as a conservative process, although, like many of nature's processes, it often leads to disaster. Its purpose was the disposal of foreign, dangerous material, and, therefore, it must be regarded as beneficent.

The Functional Diagnosis of Diseases of the Pancreas.—Dr. Wilder Tileston of New Haven gave the results of the examination of the stools of absorption experiments, and of the various functional tests in six cases of closure of the pancreatic ducts. He said that the diagnosis of complete occlusion of this duct could be made by the macroscopical examination of the feces alone. The following points were emphasized: (1) The presence of macroscopical fat in the stools. In five out of six cases macroscopical fat was found in the feces. This was usually passed at the end of defecation and solidified at the room temperature. (2) The bulk of the stools. If there was no pancreatic juice in the stools, the feces became very bulky and this was not due to any increase in the water. (3) The presence of microscopical neutral fat droplets. (4) The presence of azotorrhea or, a name he considered better, creatorrhea in the feces. This showed undigested meat fibers in the feces. He also reported five cases of carcinoma of the pancreas with jaundice; in three cases autopsies showed a complete destruction of the pancreas. There was no proof that the duct of Wirtzung was obstructed in these cases.

Sporadic Elephantiasis.—Dr. W. Gilman Thompson of New York gave a lantern slide demonstration of ele-

phantiasis nonparasitica originating in this country. This paper will be published later in the MEDICAL RECORD.

Effect on the Blood Pressure of the Various Anatomical Components of the Hypophysis.—Dr. JOSEPH L. MILLER, Dr. DEAN D. LEWIS, and Dr. S. A. MATTHEWS of Chicago presented this communication and gave a lantern slide demonstration. The results showed the presence of a pressor substance in the anterior lobe, probably confined to that portion adjacent to the cleft which histologically was pars intermedia. The pars intermedia contained a pressor substance, as shown by extracts from the isolated pars intermedia, by the colloid present in the cleft and by the contents of the cysts originating in its substance. Pars nervosa also contained pressor substance. It was not probable that two tissues histologically so different should both secrete a pressor substance. Pressor substance probably originated in the pars intermedia and later gained access to the pars nervosa. There was an absence of the pressor substance in the extract of the stalk. The pressor substance found in the pars nervosa differed from that found normally in the nervous tissue. There was a marked toxicity of the pars nervosa.

An Experimental Study of the Pain Sense in the Pleural Membranes.—Dr. JOSEPH A. CAPPS of Chicago told of the results obtained by direct irritation of the pleura in man by means of a wire passed through a hollow trocar after thoracentesis. In over thirty cases the conditions permitted of exploration of the visceral, the parietal, and the diaphragmatic pleura, and in a few instances of the pericardium.

Second Day, Wednesday, May 10

Election of Officers.—*President,* Dr. J. George Adami of Montreal; *Vice-President,* Dr. L. F. Barker of Baltimore; *Secretary,* Dr. George M. Kober of Washington; *Recorder,* Dr. Solomon Solis Cohen of Philadelphia; *Treasurer,* Dr. J. P. Crozer Griffith of Philadelphia; *Councillor,* Dr. Francis H. Williams of Boston; *Representative on the Executive Committee of the Congress of American Physicians and Surgeons,* Dr. W. S. Thayer of Baltimore; *Alternate,* Dr. Theodore C. Janeway of New York.

Is There a Specific Treatment for Diabetes Mellitus?—Dr. HENRY SEWALL of Denver asked this question and gave a synopsis of twelve cases, in seven of which the results of the treatment was of such a character as to warrant him in endorsing the method as at least worthy of trial. The method consisted in the administration by mouth of an acidulated solution of fresh muscle; he had obtained temporary curative effects from the watery extracts of muscle or of muscle and of pancreas in certain cases. Cases were reported. He acknowledged that in diabetes there might occur a temporary amelioration of the symptoms under various kinds of treatment. In order to learn the real meaning of the treatment, its therapeutic value, more cases must be observed. Evidence certainly was presented that in a certain proportion of the cases of diabetes mellitus, especially the young and middle aged patients, metabolism and the general symptoms might be improved and even the sugar entirely removed from the urine by the administration of this acidulated beef infusion.

Dr. FREDERICK C. SHATTUCK of Boston said he wished to report a very unique case. A man in his thirties was in the last stages of diabetes. The doctor who was attending him fed him on raw pancreas; he lived where he could obtain them. This patient took three raw pancreases a day and his symptoms entirely disappeared. He was able to return to his work and he was perfectly well and remained so for one year. However, one evil day he got hold of a rotten pancreas and it turned against him and he could eat no more. The disease promptly returned, the man went to pieces as fast as he could go, and died.

Dr. SEWALL said his paper was founded on clinical observation only. The point he wished to raise was, was there any specific treatment in diabetes mellitus? In deciding this question one must study the glycemia as well as the glycosuria. We needed clinical observations of these cases and then the scientific men in the laboratories might aid us.

Observations on Pernicious Anemia.—Dr. HERBERT C. MOFFITT of San Francisco presented a résumé of clinical observations on this disease. He spoke of the incidence of it in California. He had seen seven cases in one year in a town of seven thousand population; of twenty-five cases seen, only ten occurred among city dwellers. The only remedy of value in the treatment of pernicious anemia was arsenic. He presented certain facts suggesting a protozoan origin of the disease. In Washington four years ago this disease appeared. A short time ago fifteen or twenty horses died of it in Eastern Nevada. The anemia was a very grave one. The changes noted in the horse were similar to those noted in man, as well as the blood findings, the clinical findings and the autopsy findings.

The Therapeutics of Salvarsan.—Dr. S. J. MELTZER of New York said that this agent was merely an additional remedy; its use meant a new departure; it meant, in his opinion, a new epoch in medicine possibly. The Members of the Association of American Physicians were the best physicians in the United States and this meeting should not pass without something being said about salvarsan. Dr. Meltzer reviewed briefly the present status of therapeutics, and said that we had really but two specifics, mercury for syphilis and quinine for malaria. They were not discovered by anybody. Then we had a group of remedies which were intended to treat symptoms; another group of remedies to which the term physiological had been applied; then he spoke of the therapeutics of immunity. It was understood that a few patients would get well without any treatment; therefore the organism must have a certain and unknown method of getting well. Then came the discussion of the antitoxins and the vaccines. For the first time in the history of medicine had a chemical remedy been made synthetically and made a specific for any certain group of diseases. Salvarsan was a definite spirillocide. It had an effect on the malarial organism and on the trypanosomes; its action on malaria was, however, a mild one; even Ehrlich himself admitted that it would not ever be of great benefit in the treatment of this disease. The name "606" did not mean that this was an end to the investigation; it was possible for some one with a mind like Ehrlich's to continue the work at the point he left off.

Dr. HENRY SEWALL of Denver said that he had had experience with twenty (20) cases and he was very anxious to get an explanation as to some of his results and, therefore, he asked this question: In the two or three fatal cases that he had seen, could this be explained best on the assumption that the resistance to the bacterial infection was depraved? Was there a lack of defense in the body?

Notes on the Apparent Clinical Relations of Mesothelial Tumors.—Dr. LOUIS B. WILSON of Rochester, Minn., called attention to the importance of recognizing mesothelial tumors as distinct from sarcomata and carcinomata. He spoke of the origin of the capsule in the mesotheliomata and the influence on the rate and the type of the growth of the tumor. There were many variations in the cell content.

Dr. E. LIBMAN of New York said that the fever in cases of hypernephroma might, according to Israel, be remittent, intermittent, or quite irregular; it might occur without degenerations in the tumor. Dr. Libman said he had seen cases in which the fever was the most conspicuous symptom, there being but vague abdominal symptoms, and the kidney at first not being much enlarged. In such cases it was important to pay particular attention to the hardness

of the viscus, either in one part or as a whole. They were accustomed to laying stress on examining the line of hardness in cases of suspected growth; they should do the same as regards the kidney. Pulmonary metastases might be quite insidious. It was a good plan to examine the chest with the fluoroscope before operation. The bone metastases were, of course, well known, but Dr. Libman said he wished particularly to emphasize those in the cranial bones. In all cases of neoplasm he made it a practice to pass his hand over the head so as not to overlook secondary foci there before recommending operation.

Trypanosomiasis Gambiense.—Dr. C. N. B. Camac of New York reported this case. The patient was a Canadian who contracted his infection in Africa. The parasites were found and treatment was instituted almost at the same time that the infection occurred. He came first under the observation of Dr. Brodie and Sir Patrick Manson, and by the latter he was referred to Dr. Camac. The patient had been under the latter's care for over three years, had passed through several severe stages of the disease, had been under constant treatment, and had been for nearly a year without fever and was engaged in his usual occupation. For a more complete report of this case see Medical Record, Vol. 79, No. 14, April 8, 1911, page 649.

Studies of the Blood in Diseases Commonly Designated "of the Nervous System."—Drs. Joseph Collins and O. M. Kaplan of New York presented this communication. They stated that there was no disease of the nervous system dependent upon definite and unvarying disease of the blood. There were definite forms of secondary anemia that resulted from diseases of the nervous system, especially those due to toxic causes. There were definite blood conditions associated with perversion of function of some of the ductless glands, such as the thyroid. The alteration of the blood in anemias resulting from or coincident with certain chronic nervous diseases was not constant. The alteration might be in size, color, shape, and distribution of the hemoglobin in the various cells, or in additions to the cells, such as granules. The white cells did not carry the burden of chronic disease as much as the red ones, although often here, in addition to conditions where much degeneration took place, even the white cells began to show a darker protoplasmic body than was usually encountered in normal cells. The changes in size in the red corpuscles were usually encountered in the small cell or in extraordinary large ones. The changes in color varied from a very pale pink to that of the bright red, and might change in very much degenerated cells to a grayish green. The contour of the cell might change from round to a cell that could be hardly recognized as an entity, and it might present the changes from an oval and a crescent to mere fragments of a cell. The abnormal enclosures were usually the granules. In the white blood corpuscles the changes were due to the influence of invasion by morphologic or toxic elements. The great predominance of uninuclear neutrophiles directed the attention of the observer to an invasion by bacteria. In an acute disease, irrespective of the number of white blood corpuscles per cubic millimeter, the white cells showed a pronounced uninucleosis. Lead produced changes in the blood that were recognized even by the beginner. Of great importance in connection with the red cells were the granules that appeared in lead poisoning and disappeared with proper therapy. In this instance it was essential to know the number of cells affected and the degree of granulation; meaning thereby, coarse granulation or fine granulation. The more pronounced and overwhelming the affection the larger were the granules and the more numerous the cells affected by them. In proper therapy not only did the granules become smaller but the percentage of affected cells noticeably diminished.

Dr. E. Libman of New York said there were evidences of disturbances of the blood in exophthalmic goiter, for lymphemia was often found, it being present also in some cases of simple goiter. While stress had been laid on this symptom by Kocher, it was not used enough as one of the symptoms for diagnosis in the incompletely developed forms of the disease. It had a certain amount of evidence which went to show that lymphemia might be connected at times with disturbances of other ductless glands. In patients who were supposed to be purely neurotic Dr. Libman found a certain number who had a more or less marked lymphemia. He believed that they should group all the cases that showed a lymphemia separately and find out what the cause might be in the various cases. They should not place these individuals down as simply suffering from a neurotic, or so-called functional, condition.

(*To be continued.*)

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Held May 18, 1911.

The President, Dr. William M. Polk, in the Chair.

This meeting was held under the auspices of the Section on Neurology and Psychiatry.

Medical Expert Testimony.—Judge Clearwater, chairman of the committee upon law reform of the New York State Bar Association and the chairman of the committee upon reform in the introduction of medical expert testimony of that association, said that the methods now pursued in admitting medical expert testimony in civil and criminal trials did not efficiently subserve the ends of justice. That upon a preliminary examination of a medical expert witness the trial judge usually concluded that the witness was qualified to express an opinion upon the question involved, and that his ruling determined the expert's competency and the admissibility of his testimony so far as the trial was concerned. That the principal reasons that incompetent men were permitted to testify to crude opinions were that the trial judge lacked the ability to distinguish the real from the masquerading expert or possessing that ability lacked the courage to exercise it, or was willing that a brilliant charlatan should testify to reckless opinions provided that his testimony assisted to direct attention to the trial over which the judge presided. In Germany they did things differently. Their medical experts were appointed by the judges, they were allowed their expenses and a reasonable sum for their time and trouble, which was paid by the state. They were not looked upon as witnesses for either party, but as aids to the court in ascertaining the truth, and their appointment greatly enhanced their social and professional standing. A somewhat similar course was followed in Austria, France, Holland, Italy, Spain, and Belgium, but in England and her dependencies—Canada and Australia—and in the United States the unscientific and inexact method prevailed. Of late years there had been much agitation for a reform of the existing methods, but little real progress had been made. Judge Clearwater said that the reasons for the present evils were that there were no satisfactory standards of expertness; that so-called expert evidence was partisan. The result was that trials were prolonged, their expense was increased, the contradictory testimony of experts had a confusing effect upon juries, and unprincipled experts were openly hired to support causes by untruthful testimony. The expert must depend for his compensation upon the litigant for whom he testified with the result that the wealthiest litigant could produce the most imposing array of expert witnesses. Another growing evil was that the bench permitted the bar to treat the accomplished expert, who usually was a modest, unassuming man, with studied contempt. The judge reviewed the scandals arising from the prevailing methods in trials for homicide and in testamentary cases. He said that the abuse of medical

expert testimony in contests real or feigned over the wills of wealthy testators in ninety cases out of a hundred were purely and simply blackmail, and that over 60 per cent. of them were compromised by the payment of a substantial sum to the contestant, the actual and legal beneficiaries too frequently being advised by conservative counsel that an unscrupulous adversary could hire abundant medical expert witnesses to testify to the mental incompetency predicated upon the most trivial idiosyncracies of conduct. He said that the bar had cultivated and was largely responsible for the fallacy that a witness was to be discredited if he could be disconcerted ("rattled") and that thus the art of cross-examination so potent for good when fairly and properly used played havoc with hard-earned and well deserved reputations in the hands of unscrupulous lawyers. He reviewed the recent efforts to reform the introduction of medical expert testimony in the States of New York, Maine, Missouri, Rhode Island, and Michigan, and said that while the result by no means had been what was wished and hoped for, still neither the bar nor the medical profession should despair. The tendency of the day was toward reform in legal procedure and toward the elimination of those rules which were a hindrance to the administration of justice.

Expert Testimony and the Medical Profession.—Dr. Charles L. Dana presented this communication. He said that the fact that this subject had been discussed for the past twenty-five years with practically no results or progress should not discourage them from efforts to set on foot a movement which would really accomplish something in no very long time. The tendency at present was strongly in favor of more stringent liability laws and the enactment of Workmen's Compensation Acts. If this change was brought about the same results would follow as had ensued in other countries where these laws existed, namely, the enormous increase in claims for damages and a corresponding increase in the work thrown upon medical experts. In the past medical men had looked to the law to help them out of their troubles, but it had come to the point where they must do something for themselves.

Dr. Dana said that in reading over an article on this subject which he had written twenty-five years ago he found that it contained about the same criticisms and offered the same remedies that they heard to-day. Meanwhile social and industrial life and science and medicine had progressed, while the law and its methods of procedure in dealing with nervous and mental diseases were the same. The law was ever looking backward to precedents and never forward to new methods and better forms of procedure to secure justice. He had for a long time been advising young men not to become experts, because the game was not played fairly. The court procedure which made a jury of laymen pass judgment on technical questions was to blame. President Taft had said: "If one were asked in what respect we had fallen farthest short of ideal conditions in our whole government, I think he would be justified in answering, in spite of the failures we have made in municipal government, that the greatest reform which could be effected would be expedition and thoroughness in the enforcement of public and private rights in our courts." Medical men could not make lawyers change methods which were advantageous to their litigations, and lawyers were not interested and consequently protestations would accomplish nothing. The lawyer could not be expected to refuse remunerative litigation, and he naturally felt cold toward the plan to settle a lucrative contest by referring the matter to an expert commission. There was no more shining mark of human inefficiency than the way the problem of seeking justice was worked out to-day. The sum of the whole matter was that physicians must take what remedies they could; they must take the initiative. At a recent meeting of the American Neurological Association this matter was discussed by prominent neurologists from every part of the country and the following resolutions were adopted: Resolved, 1. That the methods of legal procedure in trials involving neurological testimony are inefficient, tedious, expensive; they fail to utilize effectively expert knowledge and skill and thus make it more difficult to secure justice. 2. That a fundamental reason for the criticisms of medical expert testimony lies in these faulty methods of the law, including the practice of building up cases, the misuse of the hypothetical question, and the passing upon technical questions by juries. 3. That the judiciary should by legal enactment be allowed more latitude in enlightening the jury and enabling it to comprehend the nature and meaning of the medical testimony laid before it. 4. That we urge that the legal profession seriously endeavor to secure improvements in the lines indicated, chiefly and primarily in the interests of justice and because expert testimony is necessary, is helpful to justice, and ought to be freely and effectively used in the courts. 5. That whenever possible the medical witness should testify only after he has had an opportunity to make both a mental and a physical examination of the person concerning whom the litigation is raised, and that equal right should be accorded the medical witnesses for both the plaintiff and the defendant in the examination of the person alleged to be ill or injured. 6. That we consider the hypothetical question as ordinarily presented to be unscientific, misleading, and dangerous. 7. That we recommend as advisable the adoption, wherever possible, of the so-called Leed's method of preliminary consultation by medical witnesses on both sides of the case as to its status. 8. That we advocate a freer use of appointments of commissions by the court. 9. That a period of hospital or similar form of observation of persons whose nervous and mental conditions are mainly subjective is the best method of securing impartial and accurate opinions; also that we advocate the enactment in every State of laws favoring such method. 10. That it is the sense of the association that it is inadvisable and objectionable for any of its members to occupy the position of medical advisory counsel in open court and at the same time to act as expert witness in a medicolegal case. 11. That we regard the acceptance by a physician of a fee that is contingent upon the results of a medicolegal case as not in accordance with medical ethics and derogatory to the good repute of the profession, and advocate the regulation of the practice by legislation. 12. That we are in favor of action by medical organizations that will secure a definite standard of qualification for medical men giving expert testimony. A physician should not be considered a neurological expert of the first class unless a graduate of a reputable medical college, he had paid special attention to the study of neurology for at least six years, had had opportunities for laboratory and clinical study for at least four years, and was a member of a neurological society in good standing. Dr. Dana hoped that other associations all over the country would adopt similar resolutions and recommended them to county and State societies. In regard to the hypothetical question, Dr. Dana said that if experts refused to answer such questions, unless they were put in a different style from what was often done, he believed the courts would devise some better way of bringing out the expert's evidence. Although this question might be correct as a technical legal procedure, it often made the expert ridiculous and gave him no opportunity to explain freely and fairly the views he had on a given case. If scientific men would accept this point of view better methods would surely follow.

Austen G. Fox, Esq., said that after all it was a question of raising the standard; one could not do very much by legislation. Some of the judges were weak, although they were good men and meant to administer the law according to their conscience, but sometimes they let in much

that an English judge would exclude. He was inclined to wonder whether what the Hon. Judge Clearwater had stated in regard to the hypothetical question was sound practically, though no doubt it was the law. In certain cases of injuries the claim was not infrequently partially a fake and so sometimes was the doctor. At least this used to be so. The hypothetical question was useful in giving the facts, spreading them out before the doctor.

Dr. Bernard Sachs said he hoped that the legal profession would take notice of the sentiments displayed by the better class of the medical profession. What was the remedy? Experts should be appointed by the court. In order to give expert testimony and in a proper fashion, the facts of the case should be given in an unbiased manner; as a rule, this was not done. Every expert who was asked to give an opinion in the court had hardly time for reflection. Every expert should be given a sufficient time to form his opinion. Dr. Sachs thought that every expert should be required to give a written opinion; the open court was not a place for a careful medical scientific opinion. The court should demand a written opinion. He hoped that the matter of expert written opinions would be asked for whenever it was practicable and feasible. In Europe this was the rule. With regard to the hypothetical question which was placed before the medical expert in court, in many cases it was an absurd legal procedure. Often it was beyond human endurance to listen to a hypothetical question which required for reading forty-five minutes or longer. From a legal point of view it was not a proper procedure. Why was this not practised in other countries? The judges should not merely appoint friends to do expert work; they should have a list of men, all of them experts, and from this list they should make a choice.

Dr. Edward D. Fisher said that usually cases were sent to the neurologist with the request that an examination be made and whether he would testify depended on the results of the examination. The doctor should write out an opinion, and that written opinion would go to both sides, so that if possible to settle the case out of court it might be done. With regard to expert testimony and the question of how to correct the present abuses, Dr. Fisher thought that they should fall in line with the views expressed by Judge Clearwater. It might be well to have a list of men prepared by the Academy of Medicine or the Medical Society of the State of New York, or the Medical Society of the County of New York, men who would be willing to serve. This idea of a written opinion was a new one to Dr. Fisher, but he thought it would be a beter plan than they now had. What was a hypothetical question? It was really a summary of all the facts in the case and refreshed the memory concerning what had been related both in and out of court.

Dr. William B. Pritchard said that the paper of Dr. Dana embodied a most admirable presentation of the subject; somewhat idealistic perhaps and possibly not attainable, but none the less desirable. From the many discussions of this subject to which he had listened during the past twenty years, together with his own experience, he had reached four positive conclusions or convictions: First, that the reproach of the dishonest medical expert existed only through the collusive inspiration of the dishonest lawyer, who alone made dishonesty possible; second, that the great gulf of difference between medical and legal insanity could never be bridged satisfactorily by lay juries; third, that the rules of court procedure, with quibbling technicalities, were absolutely subversive of justice in medicolegal cases; and, fourth, that, after all, the miscarriages of justice in these cases were at the expense of society rather than the individual, since, under all statutes based on the McNaughton decision, three-fourths at least of the criminal insane were responsible for their actions and should be punished therefor.

Medical Items.

Contagious Diseases, Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ended June 3, 1911.

	Cases	Deaths
Tuberculosis Pulmonalis	484	164
Diphtheria	314	28
Measles	1,780	29
Scarlet Fever	377	28
Smallpox	1	—
Varicella	155	—
Typhoid Fever	21	6
Whooping Cough	50	10
Cerebrospinal Meningitis	7	5
Malarial Fever	—	—
Totals	2,589	270

Health Reports.—The following cases of and deaths from smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended June 2, 1911.

CHOLERA.

Places.	Date.	Cases.	Deaths.
Arabia: Hodeida	Apr. 18	5	*4
India: Bombay	Apr. 16-22	1	..
Calcutta	Mar. 26-Apr. 18	..	78
Rangoon	Apr. 2-15	10	8
Indo-China: Saigon	Apr. 10-16	38	18
Java: Batavia	Apr. 9-15	10	6

*Among troops.

YELLOW FEVER

Brazil: Manaos	May 1-6	..	9
Pernambuco	Mar. 1-15	..	1
Ecuador: Duran	Apr. 16-30	1	1
Guayaquil	Apr. 1-30	31	*9
Naranjito	Apr. 1-15	1	..
Milagro	Apr. 1-30	3	2

*Including 14 cases with 3 deaths on a coaling vessel at dock.

PLAGUE

Arabia: Maskat	Apr. 16-22	8	8
Brazil: Pernambuco	Mar. 1-15	..	1
China: Amoy	Apr. 16-22	..	*..
Ecuador: Guayaquil	Apr. 1-15	3	2

THE NEW OPERATING PAVILION FOR THORACIC SURGERY AT THE GERMAN HOSPITAL, NEW YORK.*

BY WILLY MEYER, M.D.,

NEW YORK.

ATTENDING SURGEON TO THE GERMAN HOSPITAL, PROFESSOR OF SURGERY AT THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL, ETC.

WHEN the writer returned in June, 1908, from the meeting of the American Medical Association in Chicago, where thoracic surgery had been a topic of discussion, he made the Trustees of the German Hospital of New York the following proposition: If you will provide the space, I will provide the apparatus and machinery required for the performing of thoracic surgery at our hospital. They accepted.

Two tasks had thus arisen, first, to find appropriate space in the hospital; second, to find apparatus. With the second subject I have dealt in the Journal of the American Medical Association December 11, 1909. To-day attention is invited to the development of the first one.

The German Hospital is always occupied to capacity and for quite some time it looked as if there was no space to be found in either the main buildings or the annexes. Then somebody suggested the refitting for surgical purposes of the old operating room on the top floor of the old hospital, now used as living quarters of the Assistant Superintendent. After careful examination the proposition was dropped because the pumps could not be located where noise and vibration would not be transmitted to the wards below; but it suggested the looking for a location near the engine room of the hospital and the idea of placing our machinery in the latter. Attention was thus directed to a room of 15 x 23 feet in the basement of the one-story laundry building, in the sub-basement of which the engine room and boiler room are located. The room opens into the covered subway between the hospital and the dispensary buildings and their elevators. It had been used as a repair shop, had a cemented floor, whitewashed brick walls, four windows, and electric light, but no plumbing for heat, water, or drainage. Consent was obtained to let me fit it up as an operating room; then my positive differential pressure cabinet was installed therein, and our first intrathoracic operation performed on April 3, 1909.

It became, however, immediately evident that the room could be but of temporary use. With doors and windows closed during an operation the lack of proper ventilation became painfully apparent, and during the months from May to September the combined heating effect of the engine room below, the laundry above, and the sun outside created conditions which made it practically impossible to stay in the room for any length of time.

Yet as an expedient it gave good service during the other months, and by its object lesson paved the way to an all-around better understanding and appreciation of the requirements of an installation for thoracic surgery. With a horizon thus widened, a renewed full consideration of the whole subject led to the conclusion that only by the establishment in the hospital of a separate department for thoracic surgery, dedicated to that only and to be used for no other purpose, could it be hoped to obtain for the department the desired broadness of scope and scientific atmosphere.

Well knowing the difficulties of such an undertaking in an institution supported by voluntary contributions, the writer went to his friends and to his former patients and was favored by them to the extent of $14,000. The directors of the hospital voted $10,000. These sums and certain additional guarantees put the hospital in possession of a fund which justified the attacking in real earnest of the problem of housing the new department.

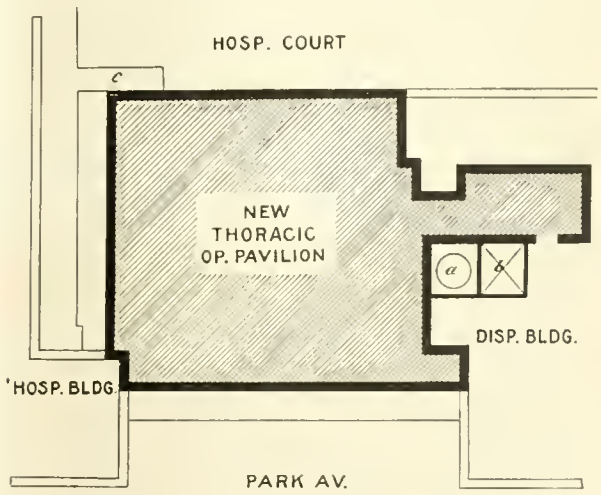

Fig. 1.—*a*, Chimney; *b*, elevator; *c*, fire escape.

Among those charged with the task of crystallizing the matter, opinion differed widely as to when to build and where to build. The hospital had other building operations in contemplation, and it was urged to concentrate them all into one grand effort rather than to prejudice the larger projects by a smaller one. But the latter was tangible, while at that time hope and doubt still attached to the former. Finally those urging immediate action for the establishing of the department prevailed. A decision was reached in favor of erecting a new story on the power house and laundry building, which had the only available flat roof of any size. (Fig. 1). The roof offered a somewhat irregular shaped area

*Read before the New York State Medical Society, at Albany, April 18, 1911.

of about 2200 square feet. Access to the same was to be had from the second floor of the hospital building by bridging the 10-foot gap between it and the laundry building, a side exit to be provided on the opposite side through a room of the adjoining dispensary building.

It devolved now upon the writer to furnish a building program. Eventually it took shape in co-operation with his brother, Julius Meyer, Consulting Engineer, in the following list of requirements:

Two separate operating rooms, one septic, one aseptic, with common instrumentarium but separated instrument sterilization; two operating stands in each room, one for the use of the apparatus which the writer had obligated himself to provide for the hospital, and one for the use of other thoracic apparatus. Skylights with northern exposure over both rooms. Water sterilization in one of the sterilizing rooms arranged to serve both operating rooms. Sterilization of dressings and utensils in a separate room, so located as to be equally accessible from both operating rooms. Anesthetizing room. One or two recovery rooms for detainment of patients near the apparatus immediately after the operation. In

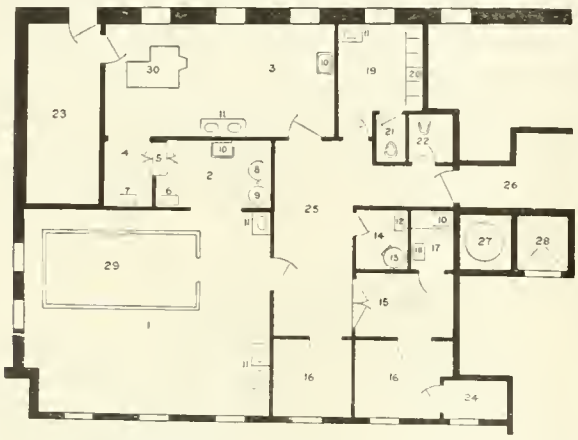

Fig. 2.—Plan view of the new operating pavilion for thoracic surgery at the German Hospital, New York. 1. Aseptic operating room. 2. Aseptic sterilizing room. 3. Septic operating room. 4. Septic sterilizing room. 5. Instrument case, accessible from both sterilizing rooms. 6, 7. Instrument sterilizers. 8, 9. Water sterilizers; water piped to (3). 10. Sinks. 11. Washbasins. 12. Utensile sterilizer. 13. Gauze sterilizer. 14. Sterilizing room. 15. Anesthetizing room. 16. Recovery rooms. 17. Pantry. 18. Electric stove. 19. Doctors' room. 20. Lockers. 21. Doctors' toilet. 22. Nurses' toilet. 23. Power room. 24. Linen closet. 25. Hall. 26. Entrance. 27. Chimney. 28. Elevator. 29. Universal chamber. 30. Positive differential pressure cabinet.

connection therewith a pantry. Doctors' room with lockers and toilet; nurses' dressing room with toilet. Laboratory. Power room, cork lined. Room for the storage of movable thoracic apparatus and of other accessories. Linen closet. Fire escape. Further requirements were: Ventilation of inside rooms by flue to the abutting main chimney; heating of operating rooms to 84° F.; electric wiring for house current and for Edison current. Further, new private elevator from the before-mentioned temporary thoracic operating room in the basement, the latter room to be used as a vestibule and preparatory room for the story above.

This program had to run the gantlet of scrutiny by the Building Committee of the hospital and its architect, I. E. Ditmars, Esq., and was objected to on several grounds. The laundry building stands on swampy subsoil. It is therefore necessary to go down deep for a firm foundation. This made the estimate of the elevator run into forbidding figures. With the private elevator fell the use of the room below as a part of the new story, an important change. The hospital ward from which a bridge was to be thrown to the roof of the laundry building is a male ward. To transport female patients through this ward appeared of questionable propriety. It was principally for this reason that it had been desired to retain in the scheme the lower room with its separate entrance from the hospital subway and to prevent the necessity of carrying the supplies for the new department through the ward, as also to prevent the passing through the same to and from operations of the staff and of visitors. These factors had now to be reckoned with, and when, in addition to that, the committee came upon the fact that the bridge involved the sacrificing of the space of a bed the bridge was vetoed. So were also the skylights, because the use of the new roof for the purpose of a roof-garden was not to be jeopardized. Next the committee decided that the new front wall must be moved five feet back from the front of the story below, in order to save a north window in one of the dispensary rooms and for architectural reasons. The available area was thereby reduced to round 2000 square feet.

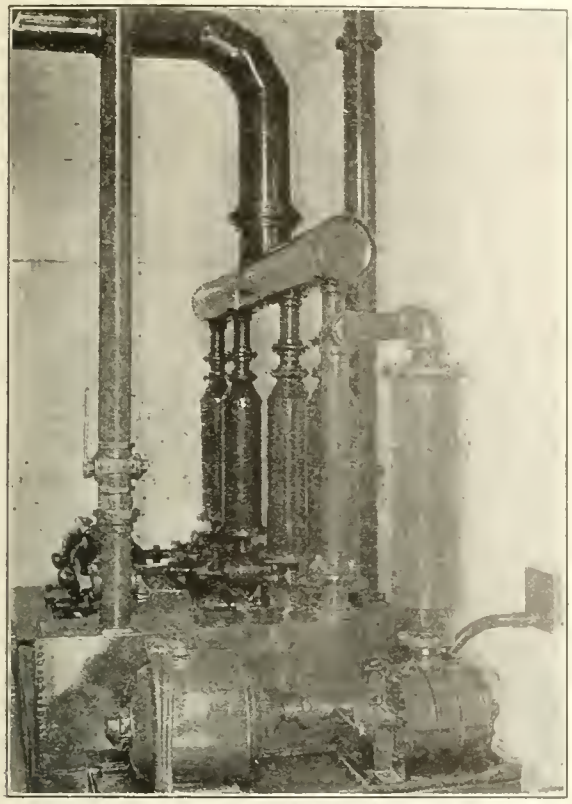
Thus shorn the proposition came back to us and completely upset all prior plans. In the face of the reduced area the question arose at once what rooms best to dispense with. Writer settled upon omitting the laboratory, because the pathological laboratory of the hospital in the new dispensary building is on the next higher floor and in easy reach from the new department; upon omitting the nurses' dressing room, they to come ready dressed and to use one of the recovery rooms, but upon retaining a nurses' toilet; also upon the omitting of a room for apparatus storage, and he decided further that the operating rooms must be kept as large as possible, dimensions of all the other rooms to be cut down.

In due course his brother came forward with the plan herewith presented, Fig. 2, which found the approval of all concerned. A vestibule has been made of the dispensary room, through which a side exit had at first been contemplated, and the main entrance to the new department has been located here. Adjoining the new vestibule is the elevator of the dispensary, which connects with the hospital subway and by means of the latter with all the public wards and the private building of the hospital, also with the laboratory. The plan speaks for itself.

Upon the basis of the same the architect was instructed by the Building Committee to prepare the working plans and specifications; assigned to him were further the letting of contracts, the superintendence of the work of building the house for the department, its plumbing, heating and wiring for electric light, and the installing of the instrument case and of the sterilizers. Contracts were let in June, 1910, and the work started at once. It was finished in April of this year.

The construction of the front wall of the new story offered some difficulty; an iron girder had to be stretched from the dispensary wall to the wall of the hospital building, a distance of about 50 feet, thus entirely bridging the laundry building. The new front wall is suspended from this girder, and the front of the new roof also rests on the same because the front wall of the story below was found too weak to carry them. The partitions are brick and terra cotta. The inside faces of all the walls and the partitions are tiled seven feet high with white glazed tiles. The floors of the operating rooms are laid with imported French tile.

The installing of our apparatuses and plant and the piping and electrical connections for same, also the installing of a new type ventilated reflector, was managed by my brother and directed by myself. It was January of this year before we got a chance



Power room: In front, pressure blower, and equalizing tank with air pipes; in rear, suction pumps, each carrying a muffler which connects into the suction pipe coming from the negative chamber; at right, exhaust pipe.

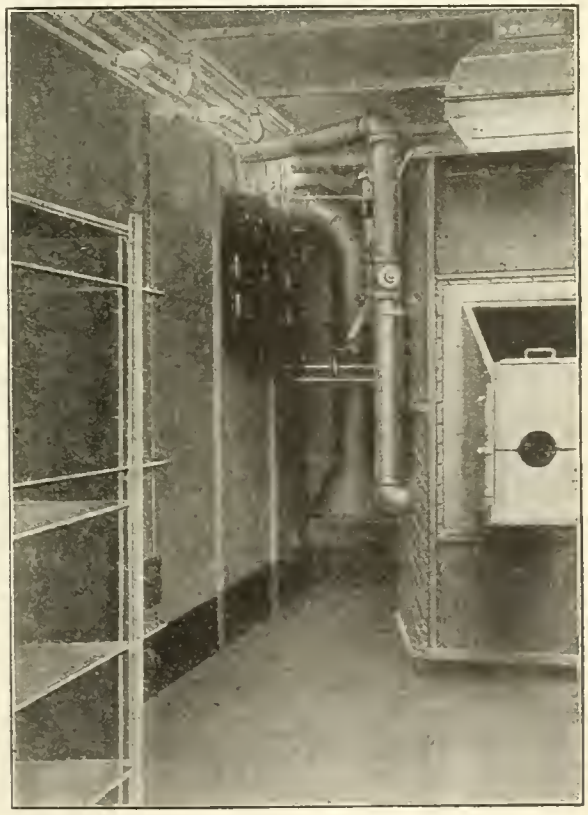
to begin with this work; it was finished by the end of March.

The equipment in the way of apparatus* with which the department starts off is in the aseptic operating room a universal differential pressure chamber consisting of a negative chamber with positive differential pressure cabinet within; and a positive differential pressure cabinet in the septic operating room. They are the same apparatuses which I had temporarily erected at the Rockefeller Institute for experimental purposes. They were knocked down there last June and placed in storage to await the completion of the new building at the German Hospital.

We thought then we had reached the end of our experiments, but found at every point when we got to work again that we were only just beginning. In fact, when we started to erect the large universal chamber at the German Hospital it was a huge experiment.

Much thought and study was given to the rebuilding of the chamber on hospital lines. When the apparatus was first erected for testing purposes at the Rockefeller Institute we had the ironwork of the chamber covered on the outside with tarpaulins of rubber sheeting for air tightening, the electric wiring put in haphazard, a temporary floor, the machinery right next to the chamber, putting up with the noise and vibration caused thereby, and had been astonished at the perfect asepsis obtained within chamber walls the surface of which did in no way conform to accepted hospital practice.

In the fall when we took the material out of storage and came to look again at the rubber tarpaulins they were found to have spoiled in spots. Not wishing to present to the hospital something that would cause considerable expense for maintenance every two or three years, recognizing also the necessity of a smooth sanitary outside surface of the chamber because the space next to it was also to be used for surgical work, we began at once to cast about for something more permanent and durable than rubber sheeting, and after full consideration of everything looking at all promising and after some experimenting, settled on hard rolled crimped copper sheets as the most likely material to give satisfaction. In order to gain experience with it and the many untried details involved, before venturing on the covering with copper of the large chamber (16 x 8 x 8 ft.),

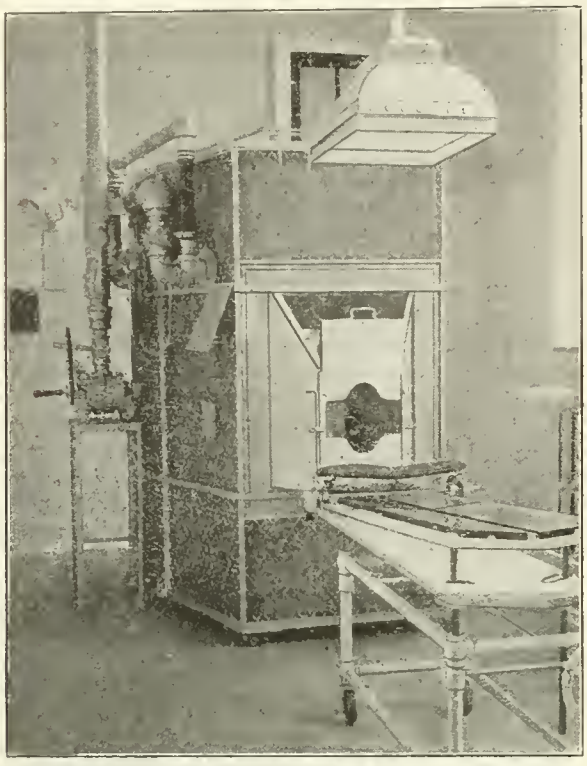


Interior of Universal Chamber. Vertical pipe in rear is air intake of negative chamber with valve for producing partial vacuum therein; in front, positive cabinet with air exhaust pipe and valve for producing positive pressure in cabinet; by means of these two valves, handled by one man, all the various pressures and variations in pressure are obtained. The differential pressure for the patient is maintained between the inside and the outside of the positive cabinet, the outside being the negative chamber. In rear, left, the switchboard controlling the motors in the power room and the several light circuits in the chamber. In front, instrument shelves; paneled walls and ceiling; cemented floor with sanitary base; ventilated reflector.

I replaced in October of last year by copper the inside rubber covering of a positive differential pressure cabinet which I am still permitted to have at the Rockefeller Institute. The experiment turned out satisfactorily. It was found that under even our light

*The apparatus is the result of three years of investigating, experimenting, and testing on my part, wherein I had the assistance of my brother. We employed the services of many firms in the manufacture of the parts of the apparatus and of its accessories. To name them all would lead too far. But, without unfairness to them, an exception can be made of Mr. Robert Kny of The Kny Scheerer Co., who at the very beginning of my experimentation put at my disposal then vacant floor space in their factory where to assemble and test the apparatus, solved thereby for me a vexed problem, and thus contributed at that time to the rapid progress of my work.

air pressure sheets of 16 oz. copper are as pliable as a fabric, and it became apparent that in covering the outside of the large chamber with copper beauty of appearance would have to be sacrificed to the necessity of drawing the copper up tightly against the



In septic operating room. On rear wall, motor control; in front, positive differential pressure cabinet, showing air supply with reserve hand blower and air exhaust with pressure valve, also gauge; in the after treatment the stretcher bed takes the place of the operating table here shown; ventilated reflector.

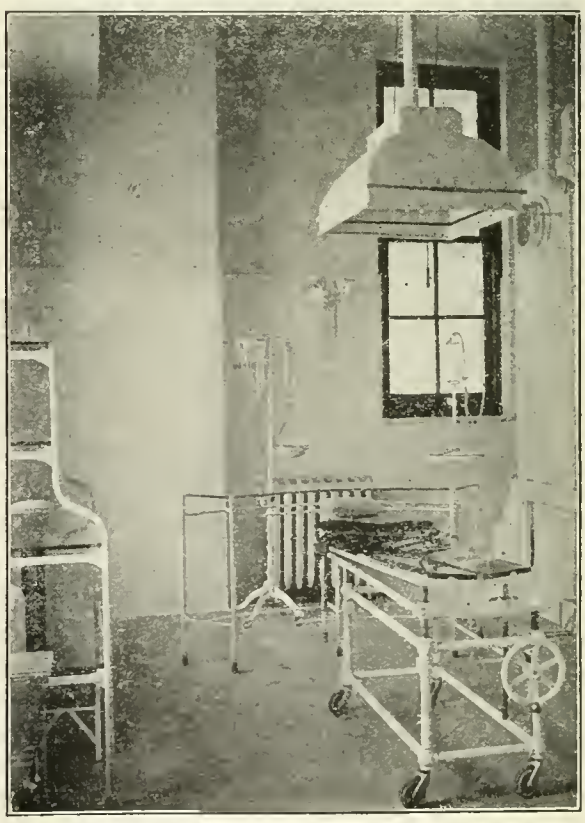
iron structure in order to prevent noise from the inward and outward bulging of the copper under varying pressures.

The question of how best to obtain inside of the chamber sanitary evenness and smoothness for walls, ceiling, and floor was next taken up and investigated. For walls and ceiling a panel board was selected, manufactured of pressed wood pulp. It has a smooth finish, is very dense and consequently slow burning. To make it fireproof it was covered on both sides with several coats of fireproof paint. For the floor and base a non-absorbent magnesite cement composition of dark brown color was selected, laid on expanded metal and on a wooden sub-floor. Ceiling, walls, and floor form a thin shell inside of the iron structure. Care has been taken so to construct that whatever variation in air pressure may be produced within the chamber, that is within the shell, the same pressure will always prevail on both sides of the latter so that it will not be pushed in.

In the light and power plant avoidance of their possible interruption has been the leading point of view, next avoidance of noise and vibration. The plant has been split up into small units, each a reserve for the other and each separately protected so that the failure of one does not affect the others.

The power plant was not located in the engine room of the hospital, as at first contemplated. It was deemed best to make the department self-contained. The current is thrown on or off in the department; thus is avoided the otherwise existing necessity of communication between new department and engine room every time the plant was to be used, and misunderstandings cannot occur. Engine room location of the plant would further have made the pipe lines long and partly exposed to the open air and would have necessitated the cutting of holes for the same through a number of heavy walls. Besides the engine room would have become crowded by the addition of our plant, and its reserve space would have been lost. Separation of the two appeared admissible, because our plant needs no supervision while running. The part the engine room crew takes in its operation is confined to oiling it up before use. While in use the control of the plant is at the operating table.

The motors and blowers are direct connected. Their speed has been adjusted to obtain in the negative chamber a proper balance between these four items: Ventilation, temperature, quick response of the gauge to the valve-setting, and noise in valve and in suction pipe. The pressure blower serves both positive cabinets, that within the universal chamber and that in the septic operating room. This is unobjectionable because thoracic operations are not yet of such frequency that the use of both cabinets at the same time could not be avoided. Reserve space in the power room and a reserve switch have, however, been provided for a possible additional pressure blower. From the pressure blower the air is sent into an equalizing tank, and pipe connections from it to the cabinets are so arranged that air can be sent in either direction.

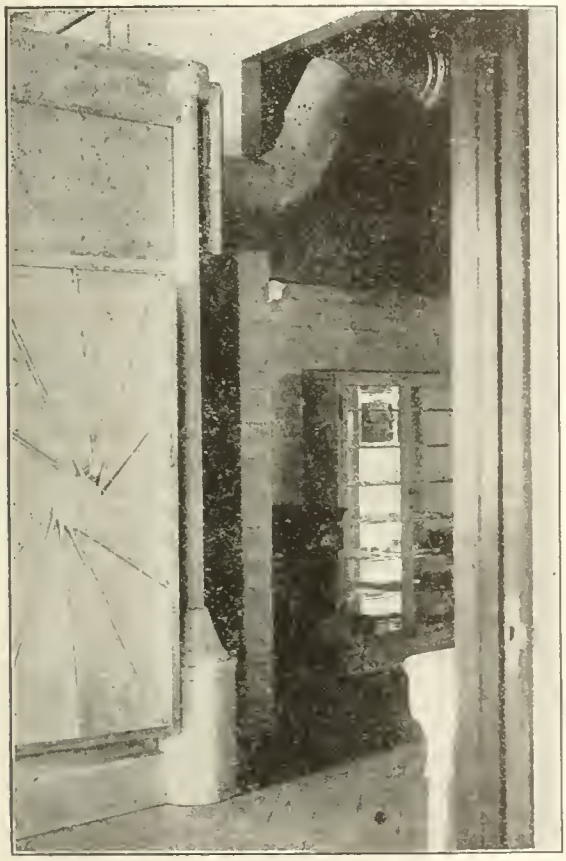


Part of Aseptic Operating Room. Showing second operating stand below ventilated reflector. A corner of the negative chamber seen at right. The large opening therein is the air intake; next to that the gauge pipe and the air pipes to and from the positive cabinet which is within the negative chamber. The operating table is the one previously described; an improved shorter one was built for use in the chamber.

Walls and ceiling of the power room are lined with 2 inches of cork. The outfits are bedded on 8 inches of cork. Motors and blowers of larger size than required are employed and run at slow

speed to reduce the noise of the impellers revolving in the blowers. In order to prevent the transmission of the still remaining noise to the chamber through the air pipes, muffling and baffling appliances have been interposed, specially designed by my brother. Ordinarily a muffler is built to deaden the noise of periodic discharges of gases or steam going from high pressure to low pressure. In this instance a constant flow of air prevails with the same pressure at either end of the muffler.

The wires coming from the Edison meters and from the house switchboard are carried first to switches of a wall panel in the power room of the new department; they are made necessary by a city rule which demands that a man repairing a motor must be able to protect himself against the starting up of the same from a distant point; for, as was



Part of Aseptic Operating Room. On left, door of universal chamber; on right, instrument case set in the partition between aseptic and septic sterilizing rooms; through it the rheostat for the pressure blower is seen on the wall of the septic operating room. Above, muffler and the suction pipe leading from the negative chamber to the suction pumps.

pointed out before, the control of the motors is not in the power room, but in the operating room, respectively within the universal differential pressure chamber. From these switches the three Edison wires and two house wires, again according to city regulation, run in separate iron pipes to the switchboard in the chamber and thence fifteen wires in another iron pipe back to the five motors in the power room, three to each motor.

The wiring scheme had to be submitted for approval to the Edison company, the Fire Underwriters, and the city. As the house voltage is 120, the Edison voltage 220, and as the two sources of current supply were to be used interchangeably, it became necessary to run our one-half-h.p. motors on one side of the Edison circuit, while their rules permit only a one-quarter-h. p. motor to be so run. They relented because we are always running two motors at the same time, and by placing one on each side of the circuit their system remained balanced. The placing of the fifteen wires into one pipe required an exception from a city rule. From October until the middle of February was consumed with negotiations, and not until then was it feasible to begin the construction of the switchboard in the chamber.

The lighting of the chamber is arranged from the point of view of the certain prevention of total darkness in the chamber during an operation. There are two circuits of twelve 16-candle power carbon lamps each. Ordinarily one is run on house current and one at the same time on Edison current. Double pole switches for each enable the running of each circuit on either source of current. One socket in each carbon lamp circuit is used to connect in a hand reflector, indispensable in thoracic operations.

In addition, there is over the operating tables the already mentioned new reflector, which has six 100-watt tungsten lamps, divided into two circuits of three lamps each, wired the same as the carbon lamp circuits. These reflectors, too, are specially built for the new department and used here for the first time. There are four of them, one for each operating stand. They embody my brother's invention of ventilation for reflectors. In operations where an intense illumination is imperative, requiring a low-hanging source of light, the great heat development of high-candle-power lamps is a drawback. On several occasions after exposure to that heat in protracted thoracic operations the surgeon's temporal arteries remained distended for several days. Here was an urgent need for improvement. The heat being transmitted downwardly through the air, if the air could be ventilated off quicker than it could be heated, the space below the lamps must necessarily be cooler than without such ventilation. Proceeding from these premises two panes of glass were arranged below the lamps, spaced some distance apart, and means provided for a flow of air through this space. In the universal chamber the difference in pressure between the air supplied to the positive cabinet and the air pressure prevailing in the negative chamber is utilized to make air flow from the supply pipe through the reflector out into the negative chamber, whence it is drawn off by the suction pumps. At the three outside stands the reflectors are piped to the ventilating flue, and thus the draft of the hospital chimney is utilized for reflector ventilation.*

The chamber is painted inside a flat white; but the two panels opposite the surgeon and his assistant are painted dark gray to provide a rest for their eyes when they are glancing up.

What we have termed "recovery rooms" are to be considered a part of the operating rooms, and not sick rooms in the ordinary sense. They come into use after the operation. The beds in the same are constructed on the general lines of stretchers; they can be wheeled to the apparatus and are of such height that the head of the patient can be introduced into the collar of the differential pressure apparatus without taking the patient from the bed. It will be seen that the recovery rooms are to be used in the beginning of the after-treatment as long as it may appear advisable to keep the patients in easy reach

*These reflectors are manufactured by I. P. Frink, New York.

of the apparatus. Exigencies may arise that require the reopening of the wound; in other cases, breathing under differential pressure after the operation has been found beneficial; again, in other cases the thorax will not be entirely closed, but will be left open for drainage, and the patient will then be kept for 24, 36, or 48 hours under differential pressure.* The first changes of dressings may also require the use of apparatus. Generally speaking, patients will be kept in the recovery rooms during the first crucial days after the operation and then be transported back to the hospital for further after-treatment.

The German Hospital of New York appears thus thoroughly equipped for the performance of thoracic surgery by the transpleural route. It is not limited to the use of the apparatuses which I have provided, but affords facilities for the use of any other thoracic apparatus and the employment of all methods appearing at all promising. For, looking broadly at the prospective evolution of thoracic surgery, I expect practice to prove that surgical work in the thorax will have to be done along the general lines of surgical work in other parts of the body; here, as there, the various anesthetics and the various methods of administering the same will be used; likewise the several postures during operation; also dry and moist methods of wound treatment, and finally the various kinds of after-treatment, that is, drainage or closing of the thoracic wound without drainage. From all of them will be selected what the welfare of each patient may at the time demand. In other words, in thoracic surgery, too, we shall learn to individualize. There is no one apparatus and no one method covering every contingency. They should all be employed wherever indicated, and should be ready for immediate use when required. It is on these comprehensive lines that the new thoracic department of the German Hospital has been conceived and constructed.

That it is necessary to have on hand all the various types of apparatus I had impressed upon me the other day when a woman was brought in *in extremis*. General anesthesia was out of the question, consequently intubation not feasible. The only position which she could endure was upright and bent over forward, therefore the use of a differential pressure cabinet excluded. Indicated were the use of oxygen applied per mask and a very slight differential pressure and local anesthesia.

Another point which I have very much at heart can now also be taken up and its relevancy be thoroughly investigated, viz., the question whether positive and negative pressure have different effect upon patients suffering from various thoracic diseases, or whether no difference can be found. In the universal differential pressure chamber of the German Hospital it is for the first time possible to approach the question under conditions which will make the results conclusive, if otherwise properly handled. To insure the latter, arrangements have been made for the attendance at operations in the chamber of specialists in the matters to be examined into. The surgeon himself cannot possibly attend to them and at the same time do full justice to his patient.

Other conditions, as thorough asepsis, easy handling of the air pressure, no lagging of the gauge behind the valve, stability of pressure between its intentional changes; artificial respiration by means of the valves of the positive cabinet and also of the negative chamber; change from positive to negative pressure, or vice versa, without interruption of the differential pressure and without change of position of patient or crew; ordinary normal anesthesia: all these points are matters the proper functioning of which is insured by the construction of the apparatus, and has been dwelt on at length on former occasions.

With increasing insight into this new field of surgery I am becoming more firmly convinced that the establishment of a special department for thoracic surgery was a step in the right direction.

700 Madison Avenue.

*Since this paper was read the first patient to be operated upon in the new department, under negative pressure (May 11), has been treated after this fashion with good success. His pleural cavity was drained for forty-eight hours, then closed air-tight, and the patient returned to the ward. In a second case, operated upon on May 25, the pleural cavity was likewise drained, the patient again being kept under differential pressure for the first fifteen to sixteen hours after the operation. The first dressing was left in place for seven days, when the drain was removed and the drainage wound covered with a piece of rubber-dam. The patient has so far made an uninterrupted recovery.

THE RATIONAL TREATMENT OF LARYNGEAL TUBERCULOSIS.

By SILVIO VON RUCK, M.D.,

ASHEVILLE, N. C.

Tuberculosis of the larynx has been at all times regarded as a most serious affection, refractory to treatment, and, in its well marked form, affording but little prospect of actual recovery in the majority of cases, especially when the disease has reached the ulcerative stage. One needs only to call to mind the almost innumerable remedies and agents with which the literature of the subject abounds to realize how ineffectual most of these have proven, even in skilled hands, except in isolated instances. It should not be forgotten, however, that a laryngeal examination of such patients is seldom made, even when the pulmonary disease is manifest, until subjective symptoms on the part of the larynx have also made their appearance and that therefore treatment is not instituted at an early period.

Leaving out of consideration the isolated instances in which tuberculosis of the larynx was believed to be primary, or such in which symptoms on the part of the larynx actually preceded those on the part of the lungs, the former do, as a rule, not appear until after the lung disease has passed the closed stage, and then often not until a far advanced stage of phthisis has been reached. Even then subjective symptoms may be absent and depend in time much upon the localization of the lesions and their extent, as also upon coexisting swelling, inflammation and ulceration. Thus the clinical statistics of coexisting laryngeal tuberculosis in from 20 to 30 per cent. of cases do not in fact represent the actual frequency, and if, irrespective of the presence or absence of symptoms referable thereto, the larynges of a large number of pulmonary patients be carefully inspected, it will be found that these figures are much too low and that the statistics of Williams of 50.5 per cent., Keller of 60 per cent., and Shaeffer of 64.6 per cent. are more nearly correct. Even their figures are exceeded if the examinations are made in the light of the tuberculin test, under which in one series of my cases 86 per cent. was reached. In 1,200 consecutive cases of pulmonary tuberculosis treated in the Winyah Sanatorium there were 725

cases, or 60.4 per cent., in which the larynx was affected. In 523 cases, or in 43.6 per cent. of the total number examined, the diagnosis could be made by laryngoscopic inspection alone. The remaining 202 cases showed slight affections, doubtful in character and causing no symptoms, which might readily have been attributed to catarrhal processes. In these the occurrence of focal reactions to test doses of tuberculin or to specific bacillary products in the course of treatment determined diagnosis. In one series of 309 cases referred to, the diagnosis was evident on inspection in 182, or 58 per cent., and determined by focal reaction in 84 others, thus raising the total to 86 per cent. Only by the repeated observation from day to day in the course of treatment was it possible to determine the diagnosis specifically in so many additional cases.

Unless, therefore, we question the specific nature of tuberculin reactions it must be admitted that tuberculous processes in the larynx are associated in pulmonary tuberculosis in the very great majority of instances. But surely the associated laryngeal disease does not become a factor in the prognosis in any such large proportion of cases as are represented by the high percentages of frequency quoted. Hence the assumption is reasonable that the usual low frequency reported constitutes, as a rule, progressive cases of both the pulmonary and laryngeal disease in which the prospect for recovery is the less the greater the extent and severity of the local affections, and that tuberculosis of the larynx in its earlier periods does not warrant so grave an outlook any more than do the more incipient changes in the lung, from which even spontaneous recoveries are, after all, not so infrequent. If this is not true, then the conclusion is unavoidable that the patient must either succumb to the pulmonary disease before the laryngeal affection becomes of serious consequence, or surviving the former must then be reserved for a worse fate. Such an hypothesis in the light of experience is, indeed, untenable, and in this connection the importance of an early diagnosis of laryngeal tuberculosis in its bearing upon prognosis from such treatment as may be suitably employed is self-evident.

The treatment of tuberculosis of the larynx may be said to be general, local, surgical, and specific, and it is the suitable combination of part or all of these measures which characterizes the rational treatment of the disease. The general treatment is that of the pulmonary disease: hygienic, dietetic, and climatic. If the patient is to be sent away from home, for obvious reasons dusty localities are to be avoided and a mild winter climate is highly desirable. Local treatment with caustics has too often been carried to extremes and is prone in many cases to accomplish more harm than good. In fact conservatism in this respect cannot be too strongly advocated, nor the routine applications of caustics to the interior of the larynx too severely condemned. The use of caustics, of which lactic acid is perhaps most frequently the choice, should be confined to local applications to ulcerated surfaces which do not show a tendency to heal under other methods of treatment. In my own practice I seldom have occasion to resort to their use, but find the chief indication for local measures to be the relief of the distressing symptoms of pain and dysphagia. When pain is a factor intralaryngeal injections of menthol oil, as first recommended by Rosenberg, often add greatly to the comfort of the patient; in others insufflations of orthoform or of anaesthesin, or the injection of mentholorthoform emulsion as formulated by Freudenthal affords relief. But that which in my hands has proven most effective in relieving pain is heroin hydrochloride in solution in water, three grains to the ounce (Rosenberg). A few drops of the heroin solution instilled warm, under guidance of the mirror, directly upon the previously cleansed ulcerated surface, often stops the pain for hours. Its local anesthetic action upon mucous membranes is so decided that its use in the majority of such cases enables one to dispense with cocaine. Neither has it the feature of cocaine, objectionable to many patients, of causing a sensation of numbness and fullness of the parts on swallowing.

In cases in which pain on swallowing is so great as to seriously interfere with the taking of food, heroin hydrochloride thus applied before meals often enables the patient to take sufficient nourishment for his needs with a very fair degree of comfort. He no longer anticipates the time of feeding with dread, while also the increased ability to maintain nutrition and to prevent loss, which without the relief afforded would necessarily result, is of the greatest importance. When outside of institution practice it is out of the question for the physician to make such frequent instillations, the heroin solution may be used in an atomizer by the patient himself. With caution in using the spray sparingly objectionable constitutional effects of the heroin are readily avoided. In the more advanced cases, when other remedies fail we must have recourse to cocaine, and especially in those cases in which because of the advanced stage of the pulmonary disease or of that of the larynx, or of both, the prospect for improvement or recovery is little or hopeless, morphine hypodermically in amount sufficient to relieve the agonizing pain should be freely given.

Surgical treatment of tuberculosis of the larynx, rendered popular in the eighties of the last century by Heryng and enthusiastically advocated by other writers in the succeeding decade, has proven disappointing in its results, and the opinion of the majority of laryngologists has gradually become more and more conservative as regards the indications for operative interference in such cases. Professor Friedrich of Kiel, as late as 1908, however, stated that the local treatment of early laryngeal tuberculosis is caustic or surgical, but he emphasized the importance of removing all tuberculous tissue, because remnants prove a source of danger by undergoing subsequent necrosis and ulceration. He quite rightly added that such an operation requires considerable ability. It may be admitted that a skilful operator may succeed in removing all tuberculous tissue from the macroscopic standpoint, but that this implies the removal of all deeper lying histologic tubercle is by no means the case, and just because such invisible remnants so often remain the results are seldom permanent and subsequent relapse is the rule. I would not be understood as denying the advantage of curettement in selected cases, but I do wish to make clear that neither operative interference nor the use of caustics is to be depended upon in itself as the means to a cure.

If the treatment is to be a rational one, then local treatment of a radical nature, surgical procedure included, becomes a matter of expediency and in certain cases a valuable adjunct to general and specific treatment. The curette may be used upon well defined ulcerated surfaces of superficial character, providing they are slow to clean off and heal. Dif-

fuse submucous infiltrations should be left intact, and only when the infiltration is circumscribed, resembling a tuberculoma, is the curette applicable, and then only if the infiltration fails to undergo resolution under specific treatment. Granulations and the grayish papillary excrescences often seen in the arytenoid fold and posterior wall may be suitably removed. In this region of the larynx good results usually follow not only as regards healing of the curetted surface, but also as concerns the voice when such lesions have been largely the cause of marked hoarseness or aphonia due to their interference with adduction of the arytenoid cartilages and approximation of the vocal cords in phonation. In ulceration of the epiglottis curettement is always indicated if pain on swallowing is distressing and cannot be relieved by palliative measures.

In general, curettement is contraindicated in patients whose pulmonary disease is far advanced and who are in an enfeebled state of nutrition, except in cases of the epiglottis as a final resort for the relief of pain, or in lieu of tracheotomy when there is great dyspnea resulting from encroachment upon the air-passage of massive and swollen infiltrations.

To the general acceptance of an unfavorable prognosis in well-marked cases of laryngeal tuberculosis I have already referred. Naturally such opinion is based upon the results obtained under suitable general management, supplemented by local and surgical treatment as adapted to the individual case, since these methods alone are commonly pursued. It is evident that something more is necessary if better results are to be anticipated, and in specific treatment we have an invaluable addition to our resources in combating the laryngeal as well as the pulmonary and other forms of the disease. The indication for specific treatment in tuberculosis of the larynx cannot, as a rule, be determined by the degree or extent of the laryngeal affection itself. Not only must the associated pulmonary tuberculosis be taken into consideration, but the general condition of the patient, the presence or absence of high degrees of fever, the existence of complications on the part of other organs, tuberculous or otherwise, must all be weighed in the balance as affecting the prognosis in the individual case both as regards the larynx and in general. If then the state of nutrition is still fair and is capable of improvement, if the extent of destructive changes in the lungs which has already occurred or is impending does not preclude a prospect of arresting the progress of phthisical processes, if there is not sufficient fever to prevent the maintenance of nutrition, then specific treatment is urgently indicated in every case of laryngeal tuberculosis in which the local disease has not progressed to the stage of massive and diffuse infiltration with extensive tissue necrosis. When the larynx is generally involved in such advanced tuberculous processes, or when there coexists marked degrees of perichondritis of the cartilages or epiglottis, specific treatment is of no avail, even if the associated pulmonary disease is not also in an advanced stage, which is usually the case.

As regards the action of specific remedies in the treatment of tuberculosis it is well known that this consists in the induction artificially of immunity to the pathologic action of the tubercle bacillus. While specific agglutinins, amboceptor, and other antibodies form in the blood of tuberculous patients spontaneously, this does not occur ordinarily in amount sufficient to permanently check the pathogenic action of the bacillus and the advance of the disease. Were this the case tuberculosis would be a self-limited affection and spontaneous recovery would be the rule. By artificial immunization the function of the cell in the production of immune bodies is increased manifold, and thus high degrees of specific resistance are acquired in the course of treatment sufficient amply to protect for even many years. In consequence the bacilli, no longer capable of growth and multiplication, gradually lose their vitality, and finally in the course of time die and disappear from the tissues. It matters not whether the pathological process is localized in the lung or in the larynx, or in other organs or tissues, the acquirement of high degrees of specific resistance is of equal importance in limiting the progress of the disease. Furthermore, under the influence of specific treatment and the increase of specific antibodies resulting therefrom, resolution takes place of recent tubercles which have not already undergone complete necrosis or fibroid change. Thus additional necrosis of tuberculous tissue is prevented, and if that which has already occurred, either in the lungs or in the larynx, is not already so extensive as to condition an unfavorable issue, the prospect for recovery is immeasurably greater if other suitable methods of treatment are supplemented by specific medication. In the larynx the slighter degrees of infiltration disappear, more marked infiltrations are reduced, leaving only such thickening as is due to sclerotic change, ulcers clean off and heal more rapidly, and if the necrotic tissue has all exfoliated in or peripheral to the ulcer, healing is permanent and additional caseation and ulceration do not follow subsequently as so frequently happens if cicatrization of ulcerated surfaces has once been secured with the aid of general and local treatment alone.

In the following series of 725 cases of tuberculosis of the larynx from which my deductions regarding methods of treatment and therapeutic indications are drawn, specific remedies were employed in all. In addition thereto and aside from general management, recourse was had to such local, surgical, or palliative treatment as seemed suitable in individual instances.

The local tuberculosis processes in the larynx at the beginning of the treatment was as follows: Tuberculous infiltrations, causing no definite subjective symptoms, but evident on laryngoscopic inspection, 215; tuberculous infiltration causing more or less decided subjective symptoms, 161; tuberculous infiltrations with ulceration superficial or deep, causing more or less marked symptoms, 147; tuberculous infiltrations, slight and of doubtful nature, in which the diagnosis was determined by focal reaction to test doses of tuberculin or to specific bacillary products in the course of treatment, 202.

On completion of treatment the results recorded were: Infiltrations—Complete disappearance of all local evidence, no longer reacting to specific remedies, 309; diminution in degree, more or less local thickening, no longer reacting, 193; infiltrations improved but still reacting, 33; infiltrations unchanged or not materially influenced, 24; ulceration during treatment, with subsequent cicatrization, some local thickening remaining but no longer reacting, 16; ulceration during treatment, disease progressive, 2; not recorded, 1. Ulcerations—Healed during treatment, more or less local thickening remaining but no longer reacting to tuberculin or specific bacillary products, 77; ulceration healed, infiltrations improving but still reacting, 8; improved, 4; not mate-

rially influenced or stationary, 22; grown worse, 36.

If all these cases in which local evidence had completely disappeared, together with those in which there remained only local thickening no longer reacting to tuberculin or to specific remedies, be accepted as apparently cured, then such a result was obtained in 595 cases or in over 82 per cent. However, it may not without reason be objected that in many instances of slighter degrees of infiltration the laryngeal disease might not have become progressive had not specific treatment been employed, or that owing to some degree of specific immunity naturally acquired in response to absorption of specific bacillary toxins from the more extensive recent tuberculous processes in the lungs spontaneous recovery of the laryngeal affection might have occurred. That this is true I am inclined myself to believe, but if true it may be accepted as further evidence in support of the contention that laryngeal tuberculosis in its earlier periods when occurring in cases of early phthisis does not warrant an unfavorable prognosis.

If comparison may be made of the results obtained from the combined methods of treatment above outlined and those commonly reported from like methods minus specific treatment, it is only fair that my own cases of slighter degrees of infiltration be excluded from the reckoning. Of these there were 417, all of which are included in the 595 cases classified as apparently recovered. Deducting these from the original 725 cases, we have 308, of which there are 161 with infiltrations sufficient in degree to cause more or less decided subjective symptoms, and 147 more advanced cases in which, associated with infiltrations, ulceration in varying extent was present, a proportion which equals 25.7 per cent. of the total 1,200 tuberculous patients and corresponds very well with the frequency of 20 per cent. to 30 per cent. usually reported. Of these 308 cases ulcerations healed and infiltrations were reduced, leaving only more or less local thickening, non-reactive to specific preparations in 178, or in 57.6 per cent.; more or less improved were 45, or 14.6 per cent.; stationary, 46, or 14.9 per cent.; grown worse, 38, or 12.3 per cent.; not recorded, 1, or 0.4 per cent.

In the treatment of the cases above reported the specific remedy employed was the watery extract of tubercle bacilli, a solution in water of the intracellular proteid of the bacillus. In the selection of a preparation this product or some one of the bacillus emulsions is to be preferred because it is our purpose to induce a bacterial immunity in the treatment of tuberculosis rather than antitoxic immunity from the use of the metabolic toxins of the bacillus to which the chief action of crude tuberculin and other preparations derived from the culture fluid is due. While the latter possess some bactericidal immunizing power, this is relatively little as compared with the other type of preparation. Moreover, crude tuberculin is by no means as safe a remedy even in the hands of experienced men and in the tuberculous larynx is liable to cause severe focal reactions which even if they do not result in lasting injury at least occasion much discomfort and distress to the patient. Of all the preparations available that employed by the writer has proven the least liable to cause undue reactions. Such focal reaction as does occur is seldom sufficient to produce any notable modification of subjective symptoms and appears in the laryngoscope ordinarily as nothing more than a slightly increased redness and turgescence of the affected parts of transient duration, rarely lasting longer than twenty-four to thirty-six hours.

As regards the permanency of results it is becoming more and more generally recognized that the great majority of those obtained by a combination of specific immunization with other appropriate methods of treatment in pulmonary cases continue without relapse, and this I have found equally true of those cases in which tuberculous affections of the larynx coexisted. The results which have been obtained in these cases of laryngeal tuberculosis were equally favorable as regards the coexisting pulmonary disease, and in the study of them it is absolutely unavoidable to credit the difference between them and the results reported in cases where specific treatment was not resorted to, to the influence of the latter. In the great majority of the cases and in nearly all of those where the larynx and lung affections had not reached extensive proportions, little more appeared necessary than to frequently observe the larynx with a view of noting the local reactions and to arrange the doses in a manner so that excessive reactions in the larynx were avoided.

The points which I desire to bring out particularly in this paper are:

The larynx is the seat of tuberculous changes in patients suffering from pulmonary tuberculosis much more frequently, and at a much earlier period, than has been commonly shown by statistics based upon clinical observation.

The laryngeal affection produces as a rule no subjective symptoms in the early stages excepting in certain localizations, and like the early stages of the pulmonary disease the larynx affection may become regressive or remain stationary and continue in a so-called latent state for long periods of time.

In every case of pulmonary tuberculosis the larynx should likewise be carefully examined for the presence of tuberculosis, and in doubtful cases a tuberculin test should be made or the larynx be inspected frequently if specific treatment is instituted on account of the lung affection.

If specific treatment is properly employed at the earliest possible period in otherwise suitable cases of pulmonary tuberculosis, a coexisting larynx tuberculosis, when likewise not in an advanced stage, will as a rule not cloud the prognosis.

ON REFLEX CONTRACTION OF MUSCLES ASSOCIATED WITH PULMONARY DISEASE.

PRELIMINARY COMMUNICATION.

By EDGAR F. CYRIAX, M.D.,

LONDON, ENG.

I HAVE read with great interest the papers by F. M. Pottenger[1] that have recently appeared on the subject of spasm of the chest muscles, particularly his remarks on spasm of the intercostals regarded as a physical sign of disease of the lungs. Pottenger states that as far as he is aware this symptom, excepting as occurring in pleurisy, has not been hitherto described. I must, however, beg to point out that in the year 1903 it was briefly described by myself in a volume entitled "The Elements of Kellgren's Manual Treatment."[2] This work expounded the Ling system of medical gymnastics, with special reference to the modifications and improvements introduced by H. Kellgren.

Quoting from this work, there occurs on page 163 the following: "In the abdomen reflex contraction of the muscles of its wall are frequently found as a result of irritative or inflamed conditions of organs in its cavity. The same state of matters obtains with the thorax; reflex contractions of the intercostal muscles result from many morbid conditions of the lungs, bronchi, and pleura." On page 312, in the course of a description on the treatment of acute croupous pneumonia, there further occurs: "* * * The impediments to respiration that lie in the muscular apparatus. These are found to be: contractions in the intercostal muscles over the affected lobe or lobes, deficient action of the diaphragm, with or without marked contraction of the abdominal muscles." On page 314 it is mentioned that in a case of lobar pneumonia affecting the left lower lobe there was contraction of the fifth to ninth intercostal spaces. And lastly, on page 313 is the following: "In two cases of pneumonia that I have treated, the kidney region of the affected side was much more tender to touch than that of the opposite side."

While it gives me great pleasure to agree in the main with Pottenger's remarks and observations, I nevertheless desire to supplement the same with certain of my own. I have specially kept under observation the reflex contraction of muscles mentioned, inasmuch as they tend to aggravate diseases of the respiratory organs by rendering respiration more difficult, and this frequently to a most marked extent. One of the objects of the Swedish manual treatment, and one which has consistently been held in view and worked out by H. Kellgren, is the removal of these impediments to respiration by means of such manipulations as stationary and running vibrations of various kinds, light frictions (to be briefly described below) and so on. It is indeed largely through these manipulations (aided, of course, by the patient voluntarily practising deep respiration) that the Swedish manual treatment can effect such great alleviations and often rapid cures, not only of chronic conditions, but even of acute ones, such as lobar pneumonia, bronchitis, etc.

Let me first briefly describe the *modus operandi* of testing for these reflex contractions of muscles that occur in connection with pulmonary disease: (1) Intercostal muscles. I entirely agree with Pottenger that "the best way is to palpate by gently pressing the tips of the fingers into the intercostal spaces and moving the hand sideways while noting the degree of resistance." (2) Erector spinæ muscles. The patient is placed in a position in which these muscles are relaxed, *i. e.* he either lies on his back or, if more convenient, on his face. The hand of the manipulator is placed so that its long axis lies at right angles to the vertebral column; the fingers are placed on one side of the erector spinæ and then, applying a certain amount of pressure at the same time, are drawn across that muscle in much the same way as the player sets a harp string in vibration. Normally a dull kind of "click" of the muscle will result; it can be clearly felt and is audible to a slight extent. If any portion of it is contracted there will be felt quite a different sensation of resistance, the "click" will be quicker and sharper, and the patient will experience a pain instead of a pleasant stimulatory sensation. Mere palpation will not enable the manipulator to define the size and degree of this contraction of muscle with anything like the certainty that results from executing a sharp friction across the mass of muscle. (3) Diaphragm. The respiratory excursion during ordinary and deep respiration and the amount (if any) of the retraction of the abdomen and participation of the abdomen, specially in its upper part, will serve as guides. (4) Anterior abdominal muscles. Palpation of these is generally at once sufficient to reveal contraction in them; irritability to touch is also a guide to some extent. Breathing exercises will also aid in determining whether these muscles are exerting their proper actions. (5) Cervical muscles. As mentioned by Pottenger, palpation is generally quite sufficient. (6) Pectoral muscles. Palpation or rolling the muscles between the thumb and fingers, as mentioned by Pottenger, will determine whether they are contracted or not.

The following is a brief list of some of the contractions that most commonly occur, together with a few critical observations:

Pulmonary Phthisis.—This condition is accompanied by contraction of the following muscles, dependent, of course, upon the site and extent of the lesion: (1) Intercostal muscles. This has been entered into in considerable detail by Pottenger, who states: "While rigidity affects all the muscles of the chest, yet it is found in greatest degree in the intercostals." I have not always found this to be the case, as sometimes there may be no contraction in the intercostals, yet a marked one in the (2) erector spinæ. Isolated slips or the whole breadth of this group of muscles may be contracted. I have in some cases, where both erector spinæ and intercostals were contracted, executed a series of frictions over the erector spinæ and their nerves of supply; the result was practically immediate; within fifteen seconds or so there occurred relaxation of the intercostal muscles, the contraction of the erector spinæ, however, remaining unchanged. While agreeing with Pottenger that the resistance of the intercostal muscles apparently disappears in advanced cases of phthisis, I would point out that the slips of the erector spinæ frequently behave in the same manner. Pottenger considers that the apparent disappearance of the intercostal rigidity is due to the removal of the supporting tissue. Whether this is true or not in the case of the intercostals, it cannot hold good for the erector spinæ; here the disappearance must be a real one. (3) Diaphragm. Two conditions are met with: (a) A kind of reflex inhibition; (b) a perverted action, in which the muscle which previously acted normally, now rises with inspiration and sinks with expiration. An apparent difficulty in using the diaphragm may be due to contraction in the anterior abdominal muscles which do not allow it to descend. Contractions of the diaphragm may exist in phthisis pulmonum before any other muscles are similarly affected. (4) Pectoral muscles. Irritability to percussion has long been considered a symptom of pulmonary phthisis. (5) Certain cervical muscles (as mentioned by Pottenger). In this connection it is of interest to quote the experiments of Boeri.[3] He found in cases of phthisis incipiens that if no abnormal breath sounds over the apex could be elicited on auscultation, yet these sometimes became audible after a few minutes' deep massage over the apex of the lung. This may have been due to removal of muscular spasm causing the excursion of the apex to increase, though Krusenstern,[4] who reinvestigated this phenomenon, concluded that it was due to mechanical irritation of the phrenic nerve causing the diaphragm to act more efficiently. (6) Serratus magnus. This muscle is sometimes contracted, and its combined action with

the pectorals seems to be the cause of the scapulæ being pulled round the side of the chest. In some cases I have seen the serratus magnus contracted, but not the pectorals. (7) Anterior abdominal muscles. Contractions here are frequent. In some cases, as already stated, they are the cause of the diaphragm not being able to descend; if the contraction in them is removed by gentle petrissage or other manipulation, the diaphragm is at once able to contract properly.

Acute Croupous Pneumonia.—This disease is almost always accompanied by the following contractions: (1) Intercostal muscles. The intercostal muscles that lie over the affected lobe or lobes are nearly always markedly contracted throughout their entire length. If pleurisy happens to be present it tends to increase the rigidity. (2) Diaphragm. Although generally bilateral, one sometimes meets with unilateral contraction of this muscle, and in this case, as would be expected, it is on the same side as the affected portion of the lung. Inability to breathe deeply, using the diaphragm, is very frequent in lobar pneumonia; this is partly due, if the base is affected, to the solid lung preventing the excursion of the muscle, but in some cases it must be reflex, as I have observed it in a case of apical pneumonia. (3) Erector spinæ. Generally the muscles on the side of the affected lobe are involved, and the contraction extends throughout their whole breadth. In pneumonia of the lower lobe it sometimes extends downward to the sacrum, *i. e.* the whole lumbar portion is affected. On the other hand, above the limit of the inflammation the contraction nearly always ends abruptly. (4) Cervical muscles. I have seen these contracted in cases of apical pneumonia. (5) Anterior abdominal muscles. These may also be affected, and in some cases unilaterally on the side of the inflammation. In pneumonia the contraction of some of the above-mentioned muscles is sometimes well marked before the signs of pneumonia are established, as the following case[2] will show: K. S., male, aged 33, had a rigor on March 27, 1900, and suddenly became very ill. March 28th, morning, temperature 104.9°, pulse 140; evening, 104.2° and 120, respectively. Nothing abnormal in the lungs during the morning. March 29, morning, temperature 105.5°, pulse 120; evening, 106° and 112, respectively. There was, during the morning, contraction of the fifth to ninth intercostal spaces on the left side; over the left lower lobe, however, was found only a moderate amount of percussion dullness, and the breathing was harsh vesicular with fine crepitations. March 30: The dullness now was absolute, and there was present tubular breathing with no crepitations unless very deep inspiration was taken; vocal fremitus and resonance were markedly increased. The contractions in the intercostals, anterior abdominal muscles, and diaphragm disappeared coincidently with the crisis in every case that I have observed: in one case of delayed crisis they disappeared only slowly. Removal of the muscular contractions by the mechanical process of frictions over the affected erector spinæ and the nerves supplying them, and vibrations along the intercostal spaces, will frequently change the nature of the breath sounds as determined by auscultation, due no doubt in great part to the air coming in and out of a partly movable instead of a very or quite unmovable lobe.

Acute Bronchitis.—In this condition one does not find so many reflex contractions as in the two foregoing. Generally the only ones met with are: (1) The upper intercostal muscles (second to fourth) are frequently contracted. (2) The diaphragm is often affected in one of the two ways as mentioned under the head of pulmonary phthisis.

How do these contractions arise? As regards the intercostal muscles and the erector spinæ, the obvious channel is through the sympathetic nerves of the lung, the remi communicantes, and the spinal nerves. The anterior abdominal muscles are also affected through the same channel, and this is the reason why the lower portion of the abdominal muscles, which are supplied by nerves that communicate with sympathetic ganglia below the lower limit of the lung, do not always undergo contraction so markedly as the upper portion. As regards the diaphragm, it is not so easy to determine the channel. This muscle has a nerve supply from the phrenics, the intercostals, and the sympathetic, either of which group may be affected. The phrenic may be directly influenced from contiguity to the lung, and this may produce direct or reflex effects on the diaphragm.[5] Similarly, involvement of the fibers of the vagus in the lungs may play a part; it must be remembered that the vagus is intimately connected with the sympathetic in the lungs, the two forming together the anterior and posterior pulmonary plexuses; also that a neuritis of the vagus has been found in advanced phthisis. The contraction in the serratus magnus is probably due to the irritation of the intercostal nerves; this may also partly explain the cause of the contractions in the pectorals. The precise channel of the contraction of the cervical muscles is not quite so easy to determine, as there are so many possibilities.

In this brief paper I have added as much as is at present necessary to the consideration of reflex contractions of muscles in affections of the pulmonary organs. I trust that it will not be long before Pottenger will be able to communicate to the profession further experiences of his own as regards this most interesting topic, and aid in clearing up the points that are as yet not so thoroughly understood.

INCONTINENCE OF URINE IN WOMEN.*

By HOWARD CANNING TAYLOR, M.D.,

NEW YORK,

GYNECOLOGIST TO ROOSEVELT HOSPITAL.

Under this title I want to bring to your attention a condition that has been of great interest to me personally, one that is very common, but one about which very little has been written. Under the heading of incontinence I include not only the absolute incontinence in patients who have no control at all over the urine, but also cases that have such imperfect control that they leak or dribble urine on all possible occasions. I shall say nothing about incontinence in men nor in children, as my experience is practically nothing in such cases; nor

*Read at a meeting of the Section on Obstetrics and Gynecology of the New York Academy of Medicine, March 23, 1911.

incontinence of urine due to vesicovaginal or ureterovaginal fistulæ, as the causes and conditions are entirely different than in the class of cases under consideration.

The incontinence may be absolute and the patient have no control at all over the urine. Or more frequently the patient have control, except at times of special exertion, such as coughing or sneezing, or riding in an automobile over rough roads. That there is in many cases a definite nervous factor is illustrated by the remark of a patient in my office during the past week. She said that she had to be careful to urinate before taking her bath, because if she first started the water running in the tub she could no longer hold the urine. There was in this case undoubtedly a nervous element combined with a weakened sphincter vesicæ.

Anatomy.—The structure of the bladder is made up of a serous coat that covers a part of its upper and posterior surfaces, three muscular coats, a submucous and a mucous coat. Of the muscular coats, the outer makes up the greater thickness of the bladder. It is largely of longitudinal fibers that extend from the posterior surface to the os pubis up over the bladder and down to the anterior wall of the vagina. The connection of this coat with the uterus is only by areolar and connective tissue, and is easily separated. The connection of this coat with the anterior wall of the vagina is more intimate and is separated with more difficulty. The middle muscular coat is circular and is not extensive. At the neck of the bladder, where the urethra begins, it is collected into a number of bundles forming the sphincter vesicæ. The internal muscular coat is irregular in its distribution, but in general is transverse in direction. The mucous and submucous coats need not be considered here.

In regard to the ligamentary connections of the bladder in the female, I would call your attention to two points; one, that it is attached in front and above to the posterior surface of the symphysis pubis, a structure that is firm and unyielding and practically never becomes displaced. Second, that it is attached below to the anterior surface of the vagina, a structure that is yielding and that is frequently displaced.

Contrasting the anatomy of the male and the female, it will be noticed that the neck of the bladder in the female is surrounded by tissues that yield easily, and therefore it becomes dilated easily. In the male, however, the neck of the bladder and the beginning of the urethra are surrounded by the prostate gland, and are less easily dilated. Also in both the female and the male the neck of the bladder is attached above to a firm unyielding structure, the os pubis, but below in the female it is attached to the anterior vaginal wall, which is yielding and frequently injured, while in the male it is attached to the prostate and rectum, which are unyielding, rarely injured, and rarely displaced. These two differences in the anatomy of the male and the female account for the much greater frequency of incontinence of urine in the female than in the male.

The incontinence of urine is due, of course, to the imperfect action of the sphincter vesicæ. This imperfect action of the sphincter urinæ may be due to a weakened condition from overstretching; it may be due to a definite loss of tissue; it may be due to a dragging on the neck of the bladder that prevents the sphincter closing tightly. The overstretching of the sphincter may be done quickly, as when the urethra is dilated surgically from without for examination or operation through it. I have seen a temporary incontinence produced in this way, but never permanent incontinence. This must be an unusual cause of incontinence, as few surgeons would operate for any extensive trouble through the urethra, and as men are more experienced with bladder examinations less dilatation is needed for examinations. The overstretching may be produced more gradually, as by a calculus or pedunculated tumor from within. This cause is mentioned in the literature, but I have never seen such a case. Incontinence of urine from overstretching of the sphincter from any cause is relatively infrequent.

Loss of tissue of the urethra may be caused by the pressure of the head during confinement, or by pressure from improper use of the forceps. The pressure may be such that it causes necrosis of the mucous membrane or a sphincter vesicæ. This, however, I think is not the usual cause of the incontinence that so frequently follows confinement. The temporary incontinence is due more probably to the swelling and edema that follow the confinement and prevent the sphincter closing tightly and controlling the urine, or to the dragging and pulling on the neck of the bladder itself.

The most frequent cause of the incontinence of urine is the dragging on the neck of the bladder itself. As I have pointed out above, in the female we have the urethra and bladder attached above to the firm os pubis, but below to the yielding anterior vaginal wall. Anything that drags on this vaginal wall will also drag on the neck of the bladder and prevent the sphincter doing its work properly. The amount of dragging necessary to prevent proper control seems to be very small. As a result of bearing a number of children there is a relaxation of the anterior vaginal wall (most obstetricians will repair a torn perineum, but practically they cannot repair an injury to the anterior vaginal wall at the time of delivery), and this relaxation of the vaginal wall, though small in amount, may be sufficient to cause the incontinence. The literature mentions cases of contraction of the scar in cases of healed vesicovaginal fistulæ as a cause of the incontinence that is sometimes seen after a vesicovaginal fistula has been closed. I have not seen such a case, but can readily understand how it can occur. A tumor rising out of the small pelvis into the abdomen can so draw on the anterior vaginal wall and bladder that it will cause incontinence.

The frequency of this condition is much greater than is usually supposed. A physician of considerable experience in gynecological work recently stated to me that all women who had had four or five children had more or less trouble in retaining the urine under conditions of sudden strain. While I think that this is too sweeping, it approaches the truth. These patients have no pain when they do pass the urine voluntarily, and they have no increase in frequency, and unless they are asked directly about their power of control nothing is said about it.

Treatment.—One approaches the operative treatment of these cases with considerable apprehension. My prognosis is always guarded, and while most cases can be cured, I never make a definite promise to a patient that I can cure her. A number of operations have been suggested for this condition. Gersuny injects a solution of paraffin about the neck of the bladder and urethra, and I believe that this method has been endorsed by Dr. Kelly of Baltimore. It does not, however, appeal to me. It seems uncertain as to the place that the paraffin is placed;

the results are not all that can be desired, and I have a prejudice against placing unabsorbable material into the tissues.

Various operations have been done on the whole or greater part of the urethra. In one the urethra is freed for a considerable part of its length and twisted even 360 or more degrees. Such an operation is dangerous, as it may lead to sloughing of the urethra and cause a worse condition than originally existed. Furthermore, the operation is wrong in theory. The trouble is in the sphincter and not in the urethra. Various operations have been done in displacing the urethra forward. Dr. Dudley, in 1905, freed the urethra and advanced the urethra so that the meatus was near the clitoris. He reports four cases with complete cure and another which had been done so recently that the result was still undecided. The operation is not associated with the same danger of sloughing that torsion of the urethra is, and I see no danger of the condition being worse than before the operation, and it is therefore an operation that is justifiable. I have never done the operation, but would not hesitate to do so.

It has been suggested to cut down on the sphincter vesicæ and resect it. I believe that this has been done. I would certainly hesitate to make the attempt. It would not be easy to find the muscle, and if there was any interference with the healing the patient would probably be in a worse condition than before the operation.

My own plan of procedure in each of the three classes of cases would be practically as follows: If the incontinence were due to overstretching and had existed long enough that it seemed to be permanent and demand operation, I would denude the anterior vaginal wall in the vicinity of the neck of the bladder and resuture it with the expectation of so puckering the urethra that the sphincter would have a better chance to act. If this did not succeed, I would advise the operation devised by Dr. Dudley. I would be very guarded in my prognosis.

If the incontinence were due to a definite loss of tissue the procedure would be much the same and I would be even more guarded in my prognosis. Fortunately incontinence of urine from either of these two causes is most unusual, as they are the most difficult cases to cure. I have never seen a case from either of the two causes.

If the incontinence is due to traction on the neck of the bladder the problem is to remove the traction. If it is due to a tumor in the abdomen, then it would mean the removal of the tumor. If the traction is due to more or less prolapse of the uterus and vaginal walls, the problem is practically that of the treatment for prolapse of the uterus.

Whatever operation may be done for prolapse of the uterus, the bladder should be freed from the anterior vaginal wall and pushed higher up on the uterus so that the drawing on the sphincter will be removed. This associated with some form of suspension of the uterus and a perineorrhaphy will usually cure the case.

The histories of three cases will illustrate the condition and the results of different lines of treatment.

Case I. Mrs A. B., aged 52, had had three children, the last 24 years previously. The patient had passed the menopause three years previous to seeing me. She had no backache, no pain in the abdomen, no discharge. In short no symptoms at all except that she could not retain her urine. This lack of control was so marked that she could not go out for a walk without constantly wetting her clothing. It is needless to say that she was a very unhappy woman. On examination, I could find little that was wrong. The uterus was anteflexed, normal in size and mobility, there was no relaxation apparent of the anterior vaginal wall and no laceration of the perineum. I was at a loss to know what to do for the patient and somewhat empirically tried a retroversion pessary and found that it cured the condition completely. This patient has now been under my care for more than three years and has remained perfectly well so long as she wears the pessary. On a number of occasions I have tried leaving the pessary out but always with a return of the incontinence. The explanation of the cure in this case is that the pessary holds the uterus a little higher than it would be without it. High enough to remove any traction of the neck of the bladder.

Case II. Mrs. B. C., aged 35 years, one child three years old. The menstruation was every twenty-four days, rather scant in amount. She complained of constant pain in the back, some pain in the lower abdomen. Bowels were regular, there was no pain or increase in the frequency of the urination but the patient was unable to control it at the time of any exertion. The day I first saw her she stated that she had tried for two weeks to get to my office to see me without wetting her clothing, but that day was the first time she had succeeded. On examination I found the uterus retroverted, a relaxed anterior vaginal wall, no operative laceration of the perineum. I tried first to that this did not entirely relieve the trouble with hold the uterus in place with a pessary but found the urine. Later I operated on her. I freed the bladder from the anterior vaginal wall, pushed it up on the uterus, and sutured in place. I then suspended the uterus with the round ligaments. This patient has now been entirely free from urinary symptoms for two and a half years excepting at the time of the menstrual period. At that time she has a little trouble due probably to the increase in the weight of the uterus and therefore a little more dragging. She is a very grateful patient.

Case III. Mrs. C. D., aged 31 years, mother of two children, the last three years ago. This patient had no symptoms other than she leaked urine with any exertion. On examination the uterus was found retroverted, a moderate relaxation of the anterior vaginal wall, no laceration of the perineum. This patient had been under the care of one of the genitourinary men here without benefit. He irrigated the bladder. She also took a course under the Emanuel Church in Boston without any help. She was advised by at least one gynecologist here in New York not to have any operation as it would not help her and was associated with the danger that she would be made worse. I advised her to have an operation on the anterior vaginal wall and a suspension of the uterus. She refused the suspension but consented to trying the operation of the anterior vaginal wall. I freed the bladder from the anterior vaginal wall, pushed it up on the uterus and held it there by suturing the vaginal wall to the uterus at a higher point than it is usually attached. It is now two years since the operation and she has no trouble at all with the urine.

CRIMINAL ABORTION.*

FROM THE PRACTITIONER'S POINT OF VIEW.

By WALTER B. JENNINGS, Ph.B., M.D.

During the year 1908 there was published a charming little volume entitled "Confessio Medici." It was issued anonymously and was favorably commented upon by the reviewers. Some months later it became known that the author was Dr. Stephen Paget, an eminent London physician. In the chapter on "Practice," the doctor cleverly likens it to the casket scene in the Merchant of Venice: "Who chooseth me must give and hazard all he hath."

In considering the subject of this paper, the writer would like to recall Hamlet's soliloquy, somewhat transposed for the occasion, with suitable apology to Mr. William Shakespeare:

"To go or not to go, that is the question:
Whether 'tis better to go and possibly suffer the pangs of newspaper notoriety or false arrest,
Or not to go and thereby lose a patient."—

But seriously speaking, it seems quite certain that such thoughts have passed through the minds of most of us, when we have been called to a case of criminal abortion; and what must be the anxiety of mind of the recent graduate or young practitioner of two or three years' experience? After having spent four years in the medical school, perhaps an interne in the hospital, he must certainly feel, when called in on such a case, that he "hazards all he hath."

In Section 1, Chapter I, on the principles of Medical Ethics it says: "Physicians should not only be ever ready to obey the calls of the sick and the injured, but should be mindful of the high character of their mission and of the responsibilities they must incur in the discharge of momentous duties. In their ministrations they should never forget that the comfort, health, and lives of those entrusted to their care depend upon skill, attention, and fidelity. . . ." Of course there are men in the medical profession, of independent means, who really do not need to practise, and any physician, rich or poor, has the right to refuse to go on a call in a given case, but Oliver Wendell Holmes once said. "To get business a man must really want it."

The writer knows of no other business or profession that is quite as precarious as the practice of medicine. In each case the physician has certain responsibilities, duties toward himself, duties toward his patient, and at times these may be momentous, but the physician does not shirk them, very often he assumes them voluntarily that he may thereby add to the comfort and health of his patient and very frequently save a human life.

It has been said that "Imagination makes cowards of us all," but with a clear conscience together with the knowledge that you are in the right, go ahead where duty calls and fear nothing.

After this somewhat rambling introduction, let us consider a given case of criminal abortion. In doing this the writer wishes to quote from Dr. Frank W. Draper's "Legal Medicine": "Our first introduction to such cases is usually when secondary and dangerous complications and consequences are developed. The common and usual course of abortionists is to send away their patients. The usual course of the patients is that they are reckless as to exposure, careless of neglect. They take cold and soon a peritonitis develops. Then it is that either in the hospital or in private practice the regular physician takes up the case in its second chapter. He notices a fetid vaginal discharge; a distended and tender abdomen; chills, vomiting, and a haggard look are in evidence. Temperature and pulse indicate peritonitis; and the womb is felt above the pubes perhaps.

"The attending physician will, of course, ask for a vaginal examination. If this is permitted he notices a patulous os uteri; observes its tenderness and that it is edematous. He finds the uterine cavity deeper than normal; perhaps some placental tissue retained." Dr. Draper uses the words "if permitted"; as the woman's consent is indispensable and no one is obliged to give evidence against herself, any attempt to make an examination without permission is, under the law, an assault. The manners and methods of a detective should be avoided. The physician should strive to secure the woman's full confidence by gentleness and tact.

In 1889 Massachusetts passed a statute to the effect that a dying statement of the victim of an abortion would be valid evidence, having the force of a sworn deposition. Draper remarks as follows: "The attending physician has it in his power to be of great help in such an emergency. Observing the patient's mental and physical condition, and her appreciation of her slight hold on life, he will note her very words accurately." Right here it might be noted that this is a very important statement and really brings out the point of the paper.

During ten or twelve years of practice, the greater part of the work being in obstetrics and among children, the writer has been unfortunate enough to have been called to treat several cases suffering from the condition under consideration. The modus operandi is as follows: The patient is prepared for a curettage, as well as the usual instruments for such an operation, together with the regular gauze and packing used in such cases. The assistant or associate is present to administer the anesthetic and the nurse or some intelligent member of the household is present to act as second assistant. The patient's history is carefully taken and written down, after which the patient makes a written statement to the effect that she was so many months pregnant, that she went to a certain Mrs. —— (address if possible), a midwife, who for a certain sum of money, produced the abortion, or inserted a certain instrument into the uterus, generally a hard rubber catheter, with the idea of bringing on a miscarriage, and that after thirty-six or forty-eight hours such a miscarriage took place, the patient having chills and fever, a great loss of blood, and the physician, Dr. X., was called in to attend her, but he was not responsible for her present condition in any way whatsoever. The patient, being of sound mind, then signs the written statement, which is also signed by the physician and one or two members of the household. The psychological effect of the note upon the patient and other members of the family is not only remarkable but astonishing.

It is explained to those present that this class of cases is very undesirable to treat, that medicolegal complications may develop, that the physician has accepted the case as one of professional duty, much against his personal feelings, and in case of her, the patient's, death, without this written statement from her, duly signed before witnesses, he, the physician, would be held responsible for the crime. Without

*Read before the Section on Obstetrics and Gynecology of the New York Academy of Medicine, March 23, 1911.

it he also might be indicted and certainly would suffer much inconvenience, notoriety, and personal injury.

At a court of law in any given case there are three important things to be remembered in regard to evidence, viz., oral, written, and implied evidence. In such cases oral or implied evidence would be of little account, and written evidence is the only one to be considered. In case the patient gets well this written evidence can be destroyed. The few cases that the writer has treated have recovered, but theoretically if a patient were about to die it seems to him that he would notify the coroner or coroner's physician so that an ante-mortem statement might be taken; but it will be hoped that this point will be brought out in the discussion.

From an historical viewpoint the following quotation might be of interest: "In Beugnot's edition of the "Assises de Jerusalem" will be found many important remarks regarding the liability of physicians in the middle ages. . . . If it were a question of simple wound or bad treatment which did not cause death, not only the physician had no right to demand any fee, but he had his right hand cut off. In case of death of the patient the physician was condemned to the gallows, . . . but before being put to death the physician should be taken through the streets of the city in order to serve as an example of his colleagues. It happened that, on account of fear regarding their liability, physicians refused their services to patients, or if they gave them they demanded a guarantee releasing them from any responsibility should the case terminate unfavorably." (Historic Notes on Laws Governing Civil Malpractice in Middle Ages. C. G. Gurnston, M.D.)

In a well-known case in this city several years ago (1899), two reputable physicians were arrested because they were "the last that attended the deceased prior to her being sent to the hospital, and on that the arrest was made." (This last being testimony of a captain of police.) "Under the law, as it stands, any physician may be arrested without a warrant being served upon him; may be arrested on the most flimsy of pretexts; may be arrested on a suspicion that would be hardly sufficient to hold a pickpocket." It appears that abortionists may advertise in the papers, they may send circulars to physicians, asking and offering inducements for cases of abortion, and they may grow fat on their ill-gotten gains without molestation by the police, while a reputable physician who is called to save a woman's life, who may be bleeding to death, is told that, if he dare attempt it alone, he does so at his peril."

In conclusion it might be stated that the subject of criminal abortion is a delicate one, that much has been written on it, that a great deal of discussion has taken place, but only two or three months ago the writer was talking with a young physician of only two years' experience who was called to such a case, but, before he accepted the call, the doctor took the time to consult a lawyer in regard to his legal responsibility, and was advised to go, as he might thereby save a human life.

And while there may not be anything very original in this paper, the fact remains that many physicians, young as well as experienced men, do allow their personal feelings to rule, thereby neglecting their duties as physicians. The writer holds that a physician should go where called, and in these cases by having a written statement from the patient he is legally protected, and the mental effect upon the family and the patient is for good. From the practitioner's standpoint, judging from the experience of some of our professional brethren, it is not desirable nor advisable to send such cases to the hospitals. A man's professional standing in the community has no influence whatever, a college professor or the recent graduate may be arrested and thereby suffer the greatest indignity and notoriety, and finally it seems to the writer that until the coroner's office is abolished and the system known as the medical examiner substituted, as in the State of Massachusetts, these indignities will still persist.

175 Lexington Avenue.

REPORT OF A PRONOUNCED CASE OF SPLENOMYELOGENOUS LEUKEMIA WITH AUTOPSY.

By MEYER SOLOMON, M.D.,

WASHINGTON, D. C.

JUNIOR ASSISTANT PHYSICIAN, GOVERNMENT HOSPITAL FOR THE INSANE.

Instances of the occurrence of pronounced cases of splenomyelogenous leukemia are not of such great frequency but that the following report may be of interest to the reader. As the patient's mental condition was more or less intimately connected with his physical disease, it is here very briefly interwoven.

B. F. B., male, white, age thirty on admission to the Government Hospital for the Insane on May 3, 1900. Family history was negative, except that patient's mother suffered from rheumatism. He was born in Pittsburg, Pa., went to school for about seven years; thereafter worked for two years in a newspaper office, for three years at glass-blowing, and then as coal-passer on the Ohio and Mississippi Rivers until his enlistment in the army in 1899, at the age of twenty-nine. While employed as coal-passer, and later while in the Philippines, he suffered from severe attacks of malaria, delirium being present in his last attack. According to the medical certificate which accompanied him on admission, he had been a heavy drinker since the age of sixteen. He admitted having had a syphilitic infection at twenty, and for this he subsequently took treatment at irregular intervals. Soon after his arrival in the Philippines, we have the first signs of the onset of his psychosis. He complained that letters from home became infrequent. Later, however, letters were received in his mother's handwriting and signed by her name, but he destroyed same without reading them, insisting that they were written by an impostor, as his mother was dead (purely delusional). He developed delusions of persecution, thought his comrades were constantly talking about his past life, and threatened to kill them if they kept it up. At that time the supposed cause of his mental disturbance was alcohol. Patient stated that just prior to his admission here he had been having fainting spel[illegible] examination on admission (May [illegible]. Height 5 feet, 4 inches; weight [illegible] cular system in excellent cond[illegible] pinkish; two scars on glans penis; [illegible] location of right index finger at metacarpophalangeal articulation; circulation good; pulse 120 but regular and of good volume; throat and mucous membranes slightly congested; spleen not enlarged; several small external hemorrhoids; fine fibrillary

tremor of protruded tongue and extended fingers. Otherwise the examination was negative.

His general mental condition throughout his stay here may be summarized as follows: Since admission he destroyed letters from different members of his family, and refused to have anything to do with any of his relatives. He had delusions of a sexual nature, showed sexual perversion, and was obscene, vile, and foul-tongued. He associated the basest thoughts, words, and actions with divine wish and direction. He became blasphemous, though at the same time he simulated a pretended reverence for God. He talked of low and degraded life, and regarded crime with admiration. Those who strove to do good he called hypocrites. His dreams were but the echo of his waking thoughts. His delusions were largely of a self-accusatory type. He wrote many letters of information concerning his family, but denied the identity of those relatives who visited him. He was hypochondriacal, had nocturnal auditory and visual hallucinations of a decided sexual trend, thought that electricity was being turned on him and that it burned his ears and toes at night, and he was skeptical about everything. He was perfectly well oriented and his memory for past events was good, though he took but little interest in current events and the affairs of the outside world. He was a case of dementia præcox, paranoid form.

Physically he seemed to be holding his own in every way. During his first two or three years' residence in the hospital he had repeated malarial attacks, and the tertian parasite was found in his blood. On January 28, 1906, he sustained a fracture of the first metacarpal bone of the right hand, and a facial cut, both of which healed kindly. On July 4, 1909, patient received a blow on the mouth, and, despite local and general treatment, continued to have repeated bleeding from the gums for a period of about two weeks. For some time prior to this date patient had shown an increasing, peculiar pallor. On August 7, 1909, when he was seen for the first time by the writer, patient showed marked pallor, hemorrhages into the cornea, decided general weakness, slightly palpable liver and spleen, moderate enlargement of the inguinal and axillary lymph nodes, rapid but full and regular pulse, and very numerous petechial hemorrhages with variously sized, particularly large ecchymotic spots most extensively distributed over the body, back, chest, abdomen, and upper and lower extremities. Urine examination proved negative. Blood and cerebrospinal fluid examination (see laboratory report below) were typical of pronounced splenomyelogenous leukemia. The usual treatment was resorted to but the patient grew rapidly worse. Edema of the eyelids and hands developed, weakness and prostration increased, marked dyspnea supervened, the pulse became very rapid and irregular, the circulation failed, and the patient rapidly exhausted till his death on August 17, 1909.

Examination of blood on August 11, 1909, by Dr. William Hough, hospital clinicopathologist, showed: hemoglobin, 30 per cent.; red blood cells, 1,920,000; color index, .78+; white blood cells, 864,000. Differential count (1,000 cells), myelocytes, 61 per cent.; transitional myelocytes, 10 per cent.; eosinophilic myelocytes, 2.5 per cent.; polymorphonuclear leucocytes, 11 per cent.; nucleated red blood cells, 5 per cent.; lymphocytes, 2 per cent.; large mononuclear cells, 1 per cent.; basophilic cells, .5 per cent.; unclassified, 7 per cent.

Examination of cerebrospinal fluid, August 11, 1909, also by Dr. Hough, showed: Pressure normal, color perfectly clear, cells per cubic millimeter 18. Differential count (500 cells), lymphocytes, 8 per cent.; large mononuclear cells, 37 per cent.; polymorphonuclear leucocytes, 3 per cent.; macrophages, 4 per cent.; transitional forms and unclassified, 48 per cent. Of the 48 per cent. transitional forms and unclassified, 26 per cent. (or 12.48 per cent. of the total number of cells) were myelocytes. These myelocytes which were present did not come directly from the blood because the spinal fluid was not contaminated with blood. Unfortunately the Wasserman test with the blood and cerebrospinal fluid was not performed at the time.

Post-mortem findings by Dr. I. W. Blackburn, hospital pathologist: Body of a young man, fairly well nourished. Skin over the whole body showed petechial hemorrhages. Skin pale; hands edematous. Cranium: Skull normal; dura mater showed a thin hemorrhagic membrane, only slightly adherent to the dura mater. It was difficult to decide whether this was a true neomembrane of pachymeningitis, or a spread-out clot. The presence of hemorrhages elsewhere and the hemorrhagic staining of the cerebrospinal fluid seems to confirm this latter opinion. Brain: Weight 1,450 grams. The arteries of the base were normal. Pia normal. The whole brain showed nothing in the least abnormal except that in the upper part of the pons there was a small area resembling a contusion, probably a small diffuse hemorrhage. The brain was abnormally pale; possibly some edema. No histopathological examination was thought necessary. Pleura: Adhesions on both sides; a little blood-tinged fluid. Lungs: Weight of right lung 750 grams; left 650 grams. Some clots in the pulmonary vessels, partly decolorized; had a pale flesh tinge. The organs were extremely edematous; bloodless. Heart: Weight 400 grams. The pericardium contained a quantity of blood-stained fluid which seemed to come from a number of subepicardial hemorrhages. Of these, the greatest and largest were over the right auricle. The right cavity filled with clots. The same petechial spots were found over the endocardium of the right ventricle. The pulmonary valves normal. Tricuspid valve admitted four fingers. Some slight patches of atheroma over the lower part of aorta near the valves. Mitral valve barely admitted three fingers but was not thickened. Aortic valves normal. Spleen: Weight 350 grams. The capsule was rather tense; some adhesions to parts in the vicinity. Pulp firm, uniform in color; Malpighian bodies not distinguishable. To feel the organ externally gave an impression of softness not verified by section. Organ enlarged. Liver: Weight 2,030 grams. Surface smooth; tissue rather pale. Organ evidently enlarged, though not especially extending below the ribs. Gall-bladder contained about 20 c.c. of thick, granular bile. Pancreas: Weight 150 grams. Organ enlarged and anemic. Kidneys: Weight of left 220 grams, right 210 grams. Over the surface were a number of petechial hemorrhages. Capsules not adherent. Section showed marked anemia of the cortex; pyramids a little darker. The mucous membrane of the pelvis markedly hemorrhagic but no appreciable hemorrhage into the cavity. Ureter contained no blood. Bladder: Filled with dark urine but no blood was perceptible. Moderate enlargement of mesenteric lymph nodes, and those of the axilla and

inguinal region were perceptibly enlarged. The adrenals seemed normal. Intestines: The contents were dark, probably from the presence of blood.

The diagnosis was made mainly from an examination of the blood during life. Dr. Blackburn has spent much time in making a special study, with colored drawings, of the very interesting, varied, and characteristic types of cells found in the blood. His report continues: Blood: The examination was made by means of Wright's stain, Jenner's stain, and toluidin blue. The predominating type of white cells were the myelocytes, of which there were vast numbers, both large and small. Some of them were simply enormous, while others were as small as a red cell. A vastly different reaction to the stains was observed among these cells, some of which were probably degenerating. All varieties of transitional forms were observed between the large and the small and the new cells and the degenerated ones. Somewhat less in number were the polymorphonuclear neutrophilic cells. These varied greatly in size, and all forms of transitional cells were found, some transitional between the myelocytes and the polymorphonuclear cells; some between the latter and the large mononuclear cells to be described below. Lymphocytes large and small were very seldom found. Mast cells or basophilic cells were found in small numbers. Eosinophiles were rarely found, and when found they were the eosinophilic myelocytes. Large mononuclear cells with granular protoplasm were found in considerable numbers. The exact nature of these cells is not clear but in the marrow of the bone in this case cells exactly similar were found, and this seems to be their source. Nucleated red cells, both normoblasts and megaloblasts, were found in large numbers. Sometimes the nuclei were double, sometimes three or more, and "clover leaf" forms were common. A large number of stippled red cells were found; sometimes a normoblast or a megaloblast would show stippling of the cell protoplasm. Polychromatophilic erythrocytes were found, some of which were also stippled. The cells found may be stated as: (1) Myelocytes, large, small, and degenerated; (2) transitional myelocytes; (3) polymorphonuclear neutrophiles, large and small; (4) transitional forms; (5) large mononuclear or "marrow cells"; (6) transitional forms; (7) eosinophilic myelocytes; (8) basophilic leucocytes; (9) lymphocytes, small, possibly some large; (10) large lymphocytes with "azur" granules; (11) stippled erythrocytes; (12) megaloblasts; (13) normoblasts; (14) polychromatophilic erythrocytes. Marrow of Bone: Smear of marrow of bone showed vast numbers of myelocytes, normoblasts, megaloblasts, and large numbers of huge mononuclear cells, which seem to be the same as those found in the blood. They stain more faintly than the myelocytes, have usually one large nucleus situated more or less eccentrically; the nuclei are by no means as large relative to the cell body as are those of the myelocytes. They are, however, huge, often as large as the whole of a myelocyte. In Wright's stain the nuclei are stained a reddish violet and the cell body a faint blue with reddish granules. In toluidin blue the nuclei are stained blue, show chromatin network and one or two red nucleoli. Rarely the nuclei are double, with red nucleoli in both. A considerable number of eosinophilic myelocytes were found—many more than in the blood.

Government Hospital for the Insane.

THE ETIOLOGY OF EPIDEMIC POLIOMYELITIS AND ITS POSSIBLE RELATION TO BERIBERI.*

By O. V. HUFFMAN, M.D.,

CINCINNATI, OHIO.

In view of the modern pathology of epidemic poliomyelitis and the kindred disease, multiple neuritis or beriberi, we can see the necessity of not permitting names to hamper our perspective in the search for etiological factors. There is increasing evidence to show that the old-time conception of a neuron being affected in its periphery without any involvement of the cell body in the cord was an erroneous one. A number of observers have found lesions in the anterior cornua of the gray matter of the spinal cord in cases of diphtheritic as well as alcoholic neuritis. Other observers have found lesions in the anterior cornua in cases of beriberi. Previous to these more recent observations Lacerda had described lesions in cases of beriberi which agree very much with those of acute poliomyelitis as we recognize them to-day. In this matter of pathological lesions we must not be influenced too much by old ideas. In going back to the year 1860 we find that at that time infantile spinal paralysis (Heine) Landry's paralysis, and peripheral neuritis were all recognized as separate clinical entities, without any pathological basis for such recognition. Later the term anterior poliomyelitis had as its basis the finding of scars in the anterior cornua of some adults who had been paralyzed since infancy. The terms anterior poliomyelitis and infantile paralysis thus became synonymous and all thought of the disease was centered upon the anterior cornua as the sole seat of lesions, but it must be added that some pathologists did not find lesions in the cord and that they continued to call the disease essential paralysis. Graves is responsible for the conception of peripheral neuritis in adults, for in describing an epidemic of paralysis which occurred in Paris in 1828 he likened the disease to the withering and beginning death of a tree at the ends of its branches. Hence in looking for the cause of recent paralysis of the spinal type in adults pathologists were mentally prepared to find changes in the ends of the nerve. This they did; they found degeneration and infiltration. But if they had examined the affected nerves in cases of infantile paralysis they would have found similar conditions. Thus it was that for years we regarded infantile paralysis and multiple neuritis as very different disease processes.

Between the symptoms of epidemic poliomyelitis, multiple neuritis, or beriberi there is no great difference, even when considered in the most orthodox way. For a long time pain was the differentiating symptom between poliomyelitis and neuritis, but to-day we know that pain is a constant symptom in epidemic poliomyelitis.

This leads me to define the disease the etiology of which we are considering. We are trying to find the cause of a disease that occurs in epidemics and produces paralysis mostly of the spinal type. As the chief characteristic of this disease is the fact that it occurs in epidemics it is essential that we do not confuse this disease with those cases of poliomyelitis or neuritis caused by chemical poisons, injuries, the toxins of various infectious diseases or meningitis. These possible causes of the paralysis

*Read before the Academy of Medicine of Cincinnati, February 20, 1911, as part of a symposium.

would have to be surely excluded before the diagnosis of the specific epidemic acute poliomyelitis which we have under consideration could stand. For this reason statistics in regard to sporadic cases cannot enlighten us. This is illustrated by an analysis of the mortality statistics for the registration area of the United States for the year 1909. This was the first year that the cases were statistically segregated and is an index of the increased attention that this disease is receiving. There were 569 deaths attributed to acute anterior poliomyelitis. The cases were widely distributed throughout the States. Here in Ohio there were sixteen; one in Cincinnati, and two in Cleveland. The duration of illness prior to death was reported in only 312 of the 569 cases. In 253, or 81.1 per cent., of the 312, the illness was reported as less than one month and the average duration of illness was 7.2 days. With such a short period of illness in the absence of an immediate epidemic we may be skeptical about the diagnosis of such sporadic cases, especially as we bring to mind epidemic meningitis, tuberculous meningitis, influenza, typhoid, diphtheria, and other infectious diseases, as well as arsenic, alcohol, lead, and many other substances and conditions which may cause paralysis and lead to such an erroneous diagnosis.

Likewise when I refer to beriberi or multiple neuritis, I mean the type that occurs in epidemics and is not accounted for by any known poison. The term beriberi used to be applied to various conditions associated with weakness and edema of the lower extremities, but in the scientific literature you will find it recognized as a disease which occurs in epidemics and causes paralysis of the spinal type. Like poliomyelitis, it most often affects the lower extremities, but may even affect cranial nerves. The edematous variety occurred in 23 of 100 cases reported by Dr. Lima. In an ordinary epidemic this edema is not such a prominent feature as one might be led to expect from accounts in text-books. So much for freeing our minds from bias so that we may proceed to review briefly the epidemics of paralysis in northern countries.

In 1887 Medin observed twenty-nine cases of acute poliomyelitis in Stockholm, but he also called attention to an epidemic of neuritis which was prevailing at the same time. It is important to note this association with neuritis, as this is the first recorded instance of a real epidemic of acute poliomyelitis. It is also interesting to note that from this time on we hear more and more of epidemics of acute poliomyelitis in Norway and Sweden, while at the same time beriberi becomes more and more prevalent among Norwegian seamen until within the last few years we find the government investigating both diseases.

In our own country prior to the recording of any epidemics of poliomyelitis we find Shattuck observing beriberi in fishermen at Boston, but waiting seven years to be convinced that it was not a curious endemic and Sequin observing the analogy of three cases of beriberi to indigenous cases of multiple neuritis at Philadelphia, two of which cases he had previously reported as poliomyelitis. Other cases of beriberi from the Orient and South America were reported at our seaports.

In 1893 Putnam and Taylor noticed that there were an increasing number of cases of anterior poliomyelitis in the hospitals at Boston. The following year Caverly reported an extensive epidemic of nervous disease of unusual type in the valley of Otter Creek in the State of Vermont. In this epidemic more than 126 persons were paralyzed in varying degrees and eighteen of them died. The disease did not limit itself to man, but also attacked horses, dogs, and fowls. A veterinarian at the post-mortem examination of a horse pronounced the disease meningitis. One of the paralyzed fowls was sent to the Carnegie Laboratory in New York and was found to have lesions in the cord which were diagnosed anterior poliomyelitis.

Prior to this in South America it had been observed that a horse pest was prevalent wherever beriberi existed. Lacerda had found lesions in the spinal marrow and meninges of cases of beriberi and believed the disease to be the same as the horse pest which was endemic on the island of Marajo. Lacerda also believed that in beriberi the virus resided in the spinal marrow. This horse pest which Lane and Lacerda observed in South America may have been due to several causes, but it is to be noted that a disease similar in its manifestations broke out among the horses of South Africa. This horse sickness in Africa was shown to be due to a filterable virus both by McFadyean and Nocard. Flexner, Lewis, Landsteiner, and Levaditi have likewise demonstrated a filterable virus obtained from cases of acute poliomyelitis.

In 1895 Caverly reported the epidemic which he had previously called a nervous disease of unusual type as one of acute anterior poliomyelitis. His main authority for a previous epidemic was Medin of Stockholm, but just about this time Medin was reporting another epidemic of twenty cases and was leaning more to the belief that the disease was a polyneuritis. From this time numerous epidemics of acute poliomyelitis have been reported in Europe and North America, and with increasing knowledge of this disease and the dessemination of medical knowledge from northern centers an increasing number of cases have been reproted from the South. From Cuba, where beriberi was endemic for many years, we now hear of acute poliomyelitis. Likewise we hear of it in Australia. According to McCullough, writing in 1908, an epidemic of acute anterior poliomyelitis occurred early in the summer of 1899 on the island of Guam. The disease was imported on the Spanish steamer *El Cano*. The epidemic was not extensive and was confined to one side of the island.

As this paper is necessarily brief, I cannot stop to enumerate the various epidemics which have been reported, but will epitomize the etiological factors. Seaports are usually the focus for epidemics. Inland epidemics may follow. The epidemic prevails during the summer months. Children are more susceptible. Several members of a family may succumb. There is some evidence to show that it is contagious. Quarantine has seemed to be effective in checking the spread of the disease. The epidemic does not continue the next spring, as the virus is probably killed by cold weather. If the virus were carried by water, we should expect a more widespread epidemic. If spread by a common ecto parasite, such as the louse, flea, or bedbug, we should expect the epidemic to continue during the winter. If spread by a mosquito or insect imported from the tropics with fruit, we should not possibilities come to mind in the way of protozoon be surprised. With this hypothesis many other parasites that may undergo a life cycle in the body of an insect, not necessarily a biting insect, as the insect and virus may be swallowed. The fact that

certain protozoa may change their form and pass through a filter leads one to believe that the virus may prove to be a protozoon although a number of animal diseases are due to similar filterable viruses.

In the bacteriological investigation of acute poliomyelitis a number of experimenters have produced paralysis experimentally in various animals by a variety of bacteria, but most of the work has been shown to bear no relation to the specific epidemic acute poliomyelitis.

Wickman, who studied 1,031 cases in Sweden in the summer of 1905, called attention to the polyneuritis which accompanies the poliomyelitis and observed that dogs and other animals were affected. This should make one to study the disease in animals. That domestic animals are similarly affected had been reported by Caverly in the Vermont epidemic, and more recently Free, who investigated an epidemic in the Allegheny Mountains, reported that swine and chickens are similarly affected. These facts should make us suspect the food which is common to all, for dogs, swine, and chickens receive the same food in the form of garbage. In Norway, Java, and England this so-called polyneuritis of chickens has been studied and has been produced experimentally by means of feeding. So far as I am aware all of the work is open to criticism, inasmuch as the spinal cords were not examined.

Certainly the analogy and the association of poliomyelitis and beriberi are worth considering. Beriberi is fairly common in the tropics, especially in Brazil, Japan, and China. It attacks children, as well as adults. A predisposition to beriberi is created by a prolonged faulty diet. In the North infants are more apt to be predisposed by a faulty diet than adults, and for this reason perhaps they acquire poliomyelitis more easily than adults. For many years beriberi has been associated with a diet of rice; this should make us look for such a factor in an epidemic of poliomyelitis. Rice, barley flour, and any other food that is imported should be suspected. The fact that the epidemic of poliomyelitis which occurred in New York late in the summer of 1907 was preceded by a visit of Brazilian warships to New York and Norfolk with beriberi present among the crew is too remote to prove a connection, but it does serve to prove that beriberi was afloat on the Atlantic. All of these ships have rats aboard, and I should not be surprised if rats in some way carried the virus of beriberi and through them the food became contaminated. This might explain the irregular distribution of beriberi. It remains for many of these hypotheses to be disproven before we learn the true nature of epidemic poliomyelitis.

I might add that in the recent efforts to locate the virus of beriberi all of the organs of the body have been examined and experimented with, except the spinal cord, and in each instance the results have been negative. In the experimental work with poliomyelitis in monkeys there has been no case of spontaneous development of the disease in monkeys caged with the inoculated subjects. This shows that the virus is not the only etiological factor.

In this paper it is not contended that poliomyelitis is a polyneuritis. We should not use names unless we are very certain that these names stand for very definite realities. The epidemics of paralysis which have been called poliomyelitis are quite similar to epidemics of paralysis which have been called by other names in other parts of the world. The clinician holds neuritis to be very distinct and apart from any lesion in the cord, yet the axis cylinder process in the nerve and the cell body in the cord are together one cell, the neuron. Where I have used names I have done so because of necessity. My aim has been to broaden our horizon in recognizing poliomyelitis and to broaden our field in the search for causative factors.

THE DISTRIBUTION OF TRACHOMA IN CUBA.

WITH NOTES IN REGARD TO A NEW PROCEDURE IN THE TREATMENT.

By FRANCISCO M. FERNANDEZ, M.D.,

HAVANA, CUBA.

Having been commissioned by the Secretary of Health of Cuba to combat the various epidemics of trachoma which from time to time have made their appearances in different parts of the island, and which in some places have undoubtedly assumed serious aspects, we have had the opportunity of studying in this way a large number of trachoma cases. The unlimited experience afforded by the clinic of Dr. Santos Fernandez and experience with private patients enables the writer to speak about the existence of trachoma in Cuba and about the results obtained with the different forms of treatment. Since the beginning of our work in Cuba we were inclined to believe that trachoma existed in Cuba in greater proportions than was thought. In effect the large contingents of armed men that during many years had crossed and recrossed the country and had camped in the various places; the absence of hygiene inherent in this social class; the intense political agitation that had so deeply disturbed our country, exiling hundreds of thousands of citizens; and the criminal reconcentration of country people in the towns by Weyler; all this formed a sufficient group of causes to render very easy the propagation of trachoma. This had existed for a long time in Cuba, but always to a slight extent. Together with all this there is the scarcity of water in some places, the lack of personal hygiene (fortunately rare in Cuba) in others, and the complete absence of public health service that has prevailed until a few years ago. These were causes that rendered the propagation of the disease extremely easy. Our suspicions have been confirmd more and more as time passed, and now, after having seen the gradual and rapid increase in the cases of trachoma at the clinic of Dr. J. Santos Fernandez, after having seen the large number of children in the schools of Havana and other cities affected with this disease, and especially after having examined in several places, very far from each other, large numbers of trachoma patients, I am now perfectly satisfied that my suspicions were true, and that there are in Cuba a large number of cases of trachoma, although this fact should not attain alarming character.

In December, 1909, we had the opportunity of eradicating feces of 108 cases of trachoma in Calvario, a small village near Havana, where there is no drinking and little of any other water. This fact would make it easy to see that hygienic rules would not be very closely adhered to. There were in that village during our revolutionary wars large armies of Spanish soldiers, and this fact, together with the absence of water and the presence there of immigrants working on the construction of roads, would have been more than sufficient to propagate the disease among the school children there. In January, February and March, 1910, we were ordered to treat over 65 cases of trachoma in Nueva Paz, a town situated more than eighty miles from Havana. Although there is a sufficient supply of water at that place, the dust and dryness of the climate facilitated the propagation of the disease, and it should also be considered that there were large armies stationed in that city during the war. Owing to the vast extent of the district it was impossible to cover it all. In Santiago de las Vegas, ten miles from Havana, since November, 1910, we have been fighting against a large epidemic of 460 cases of trachoma. In this place there has been for several years a reformatory school, where incorrigible children have been sent in large numbers. This kind of pupil has rendered easy the propagation of trachoma, and we have been informed that there occurred, in fact, frequent affections of the eye among them. In Matanzas Province we have had the opportunity of examining a great many cases of this disease, and in this province, as well as in Las Villas, we are aware that trachoma exists to some extent. In Remedios, Las Villas Province, an inspection made in the schools by the health officer gave a large number of cases. In Holguin, Province of Oriento, there occurred in 1901 a large epidemic of trachoma, over 2,000 cases which were under the charge of Dr. Vincento Gomez. A distinguished ophthalmologist of Santiago, Dr. Comas, informs us that trachoma is on the increase in that region. Holguin and Santiago are overrun with it. Manzanillo, Bayama, and Guantanamo have less. Dr. Comas had 122 cases during 1910; of these 40 per cent. were children. In all the trachoma cases that he has seen Dr. Comas has not found one in a negro; while in the 2,000 cases we have seen we have found at least 60 negroes affected with trachoma. There is undoubtedly a certain relative immunity of the negro race toward the disease, and Comas has ascertained that during the first American intervention (1898 to 1902), in Santiago de Cuba Province, at least, trachoma was epidemic in the towns that were occupied by "white armies," while in those where there were negro soldiers there occurred few cases of the disease.

In Dr. J. Santos Fernandez's clinic, which registers almost 3,000 new patients every year, the progressive increase of trachoma is easily seen. From 1875 to 1902 the percentage of trachoma was 2.25 per cent. of all cases. From 1903 to 1907 it rose to 4.91 per cent. In 1908 it was 5.88 per cent. In 1909 the percentage was almost

8, and in 1910, 10 per cent. of the ophthalmic cases had trachoma. This increase is not limited to Cuba; Mexico has seen the same increase, and although up to a few years ago it was thought that the natives there were immune to trachoma, they had soon become convinced of their error. Fortunately for Cuba, we rarely see the very acute forms of trachoma, nor the extremely chronic form so common in Egypt. And this positive benignity is also noticed in the scarcity of the grave complications.

In regard to the treatment, we have naturally had the opportunity to employ all kinds of measures. The only surgical procedure that has given us satisfactory results is the excision. More than half of our cases have thus been cured. We want to mention, especially, a new form of treatment which has given us excellent results, and which would, no doubt, be very extensively employed if it were known. Up to some time ago we were almost convinced of the futility and absurdity of pretending to cure trachoma by medical means. An immense number of cases in which we thought some drug had done good results soon showed that this was not true. Something has transpired, however, that has obliged me to modify my radical view against medical procedures. While investigating the large epidemic of trachoma in Santiago de las Vegas, already referred to, a Mexican colleague, Dr. La Torro, from Veracruz, told me of the wonderful results he had obtained from the use of sodium salicylate in trachoma cases. We were somewhat skeptical about trying it, but decided to give it a trial, and selected at first 200 cases, and later 100, in which I gave the method a thorough trial. The results I frankly confess were far superior to what I had expected. In a short time the granulations disappeared and the conjunctiva was left smooth and clean as in normal cases. The method is as follows: With a cotton swab immersed in cocaine or alypin solution the conjunctiva of both lids is bathed to produce anesthesia, the strength of the solution used being 10 per cent. One minute later another cotton swab well soaked with distilled water is impregnated with powdered sodium salicylate and rubbed with some degree of strength against the granulations in front and behind the cul-de-sac. The lids are, of course, very well averted. In some cases the drug causes some burning; in others this is intense, but in all cases the burning sensation disappears in a short time. For two or three days it can be seen how the conjunctiva becomes more and more smooth, the granulations disappear by reabsorption and by destruction; friction used destroys many and increases a limited inflammation provoked by the salicylate. The treatment is repeated every three or four days, and more than half of the cases received five or six applications. Of nearly 400 cases thus treated we have failed in less than ten cases.

Enterospasm.—Fowler notes that there is a class of patients who present symptoms comprising intermittent attacks of constipation without pain or with slight pain, referred either to the epigastrium or about the umbilicus. These patients may have occasional nausea and vomiting. The symptoms may be confused with chronic appendicitis. These are cases of enterospasm of the large or small intestine.—*Long Island Medical Journal.*

Primary Sarcoma of the Pelvic Connective Tissue.—Enrico Mertini says that the loose connective tissue between the layers of the broad ligament rich in vessels and lymphatics is a favorable location for inflammatory processes as well as for growths of all sorts. Fibromata are frequent, sarcomata are less so. The point from which such a sarcoma arises is not easily demonstrated. They may begin anywhere and go on rapidly infiltrating the surrounding tissues, rising into the abdomen, or descending into the pelvis and causing pressure symptoms in the bladder and rectum, and sensation of weight in the pelvis. Such a tumor may take up the space that should be occupied by the rectum and push down into the vulva and labia. The prognosis of these very malignant tumors is very bad. When operated on they recur almost immediately and when not operated on they cause death from cachexia and pressure symptoms.—*Annali di Ostetricia e Ginecologia.*

The Suprasymphysis Cesarean Section in Practice.—Cesare Micheli gives the technique of the suprasymphysis operation for cesarean section: incision of the abdominal walls in the subumbilical region down to the peritoneum, separation of the peritoneal layer from the posterior face of the bladder and anterior portion of the fundus uteri, longitudinal incision of the uterus, removal of the fetus, suture of the uterus, and closure of the abdomen. When there is no possibility of a normal delivery of the fetus by the natural passages, on account of contracted pelvis, but there is an open amniotic sac and danger of an infected peritoneum, the classical section becomes impossible. Premature labor, podalic version, forceps, and craniotomy have given place to other measures. Version and forceps are of little value in contracted pelvis, since only in minor degrees of contraction can they be useful. The suprasymphysis cesarean section will take their place. This operation is indicated in delivery for eclampsia and in central placenta previa.—*Rivista Ospedaliera.*

Advantages and Inconveniences of Antidiphtheritic Serotherapy.—M. V. Péchère, after a careful discussion of the value and disadvantages of antidiphtheritic serum, gives us his conclusions. The neutralizing influence of antidiphtheritic serum against the poison of diphtheria has been shown in therapeutics; the favorable results of the serum when freshly prepared has proven of great value to the human race. Serotherapy has lessened the mortality from 50 per cent. to 12 per cent. The action of the serum is quicker the earlier in the disease it is injected. It has a specific action only against the Klebs-Loeffler bacillus, and not against the complicating bacteria, such as streptococcus, staphylococcus, and pneumococcus. The injection of serum causes at times pathological phenomena, but these are of a benign nature; they are urticarial eruptions, increase in temperature, presence of albumin in the urine, and arthropathies. Their gravity and number are not sufficient to be dangerous to the patient; we should consider antidiphtheritic serum the best treatment for diphtheria, although we should make use of local treatment for the throat at the same time.—*Bulletin de la Société Royale des Sciences Médicales et Naturelles de Bruxelles.*

Retroversion Flexion in Mental Maladies.—R. Schockaert advocates a careful genital examination in every case of mental alienation in women, whether in asylum or private practice. The diseases and displacements of the genital organs have a very marked influence on both the mental and physical condition of the organism. Symptoms on the part of the stomach, intestines, and rectum, as well as the mind are produced by lesions of the genital organs. Hysteria, melancholia, and psychopathies may result from gynecological troubles. One of th
sions that oftenest has this result is retrover

CHORIOEPITHELIOMA AND THE CANCER PROBLEM.

PERHAPS the most remarkable of "cancers" is the newgrowth of the female genital organs first described as sarcoma of the placental site by Sänger, and later termed chorioepithelioma. It occurs only after pregnancy, whether normal, interrupted, extrauterine, or one followed by the expulsion of an hydatidiform mole. It is perhaps the best example of the "parasitic" nature of tumors, for it takes origin in the fetal epiblast, grows rapidly, infiltrates the muscularis of the uterus, and quickly forms metastases transported by the blood-vessels. Vagina and the lungs are usually the first to become secondarily involved, and later liver, spleen, and other internal organs become the seat of metastases. Malignancy seemed then, at first, to be a very characteristic property of the tumor.

However, hardly was this chapter in the study of the disease closed, a study to which Marchand and his pupils have contributed most, when observers began to note the more or less frequent exceptions to the malignancy of chorioepithelioma, and it is this phase of the problem that Hitschmann and Cristofoletti exhaustively deal with in the *Wiener klinische Wochenschrift* for May 11 and 18, 1911. In many cases, mere partial excision of the tumor was followed by subsequent cure; in others, spontaneous regression and disappearance of the tumor took place, occasionally even after vaginal metastases had appeared. It seemed, then, as if malignancy must have a different meaning in the case of this neoplasm, for histologically there is no difference between malignant and benign chorioepithelioma. Both indeed are but little different from the normal trophoblast in its early stages; the tumor tissues grow rapidly, show numerous mitotic figures, and possess to a high degree the trophoblastic property of eroding blood-vessels and of growing within them. Rapid growth, infiltration of the surrounding tissues, involvement of blood vessels, metastases—all are present, yet malignancy or non-malignancy seems to depend upon something quite different from these classic elements of malignancy in other "cancers."

Hitschmann and Cristofoletti have carefully studied the reported autopsies in cases of chorioepithelioma and have come to the conclusion that the dissemination of the tumor and, therefore, its malignancy depend a great deal upon the condition of the efferent veins. Trophoblast with all its wonderful power of growth depends upon maternal blood for nutrition, and the same holds true to a great degree of chorioepithelioma; thrombosis of the large veins about the uterus not only prevents the mechanical transportation of the tumor particles, but leads to local degeneration and necrosis of the tumor itself. This point may well serve to explain the varying behavior of the tumor so far as malignancy is concerned, as well as the frequent rapid dissemination after operative procedures. The authors, therefore, recommend an abdominal, instead of the vaginal, operation in each case, so that the parametric and the spermatic veins may be tied off, before the vaginal or the uterine tumor masses are at all disturbed. Curettage is a dangerous procedure in any case of chorioepithelioma.

The views of Hitschmann and Cristofoletti are important because of the inherent interest of the subject of chorioepithelioma itself. Still more important, however, is the relation of the subject to the general cancer problem. The natural history of this tumor shows remarkably well how important is the reaction of the tissues of the "host" to any tissue elements that have lost their subjugation to the general needs of the organism, or have abnormally continued functionating after the need of some special function is gone. In the case of chorioepithelioma, gestation is of course such a function. It may be that a careful study of the maternal tissues and blood, and of these elements in women with chorioepithelioma, combined with experimental work in the same field, will throw more light upon the cancer problem than the propagation *ad infinitum* of the Jensen or other animal tumor propagation which nowadays is such a rage in many centers of cancer research.

TUBERCULOSIS AS A DIATHETIC DISEASE.

NOT all physicians are convinced of the contagiousness of pulmonary tuberculosis. In fact, a considerable number are opposed to this view. In the *Dietetic and Hygienic Gazette,* March, 1911, are two papers by physicians who doubt, or rather deny, that pulmonary tuberculosis can be conveyed from the sick to the well. Dr. Homer Wakefield of New York discusses the diathesis of tuberculosis and gives it as his opinion that too much attention is given to the view that tuberculosis is contagious and that too much money is expended in carrying out measures in consonance with these beliefs. In short, Wakefield is a champion of personal hygiene in the fight against tuberculosis rather than of bactericidal measures.

The most interesting part of Wakefield's paper, however, is that in which he propounds his opinions as to the importance of tissue density as a factor in the causation of consumption. A lowered tissue density is a predisposing factor to infection as distinguished from the susceptibility to general infection involved in loss of density *per se.* Sound tissue is never infected in nature by a parasite; therefore, in order that infection may occur there must

be a certain amount of tissue degeneration. But according to Wakefield this proves that all so-called strict parasites are relative or facultative saprophytes requiring some degree of tissue degeneration for their development. Thus the tubercle bacillus is in reality relatively a saprophyte, and if it is, as the bacteriologists say, the most typical of parasites, all parasites are saprophytes and are incapable of self-projected infection, except in the event of loss of tissue density which, says Wakefield, must be admitted as a degeneration of the tissue. There are several causes of a diminution of tissue density, but when the density is lowered the soil for invasion by the tubercle bacilli is created and increased with the progress of the degeneration and final decomposition. Anything that lowers the tissue density of an individual renders him susceptible to infection.

As the predisposing cause of pulmonary tuberculosis is a lowered tissue density, that is, degenerated tissue, condensation of tissue is the goal to be sought by all who would avoid or who have contracted tuberculosis as a prevention or cure. Condensation of tissue is brought about by the treatment of consumption introduced some few years ago by living an outdoor life in cold, dry climates and by consuming large quantities of nitrogenous food. With the condensation of the tissue the soil favorable to the activities of the tubercle bacillus is taken away and the bacillus dies from lack of nourishment.

WASHING AND HEALTH.

Good old John Wesley's oft-quoted axiom that cleanliness is next to godliness does not find favor with all modern sanitarians or authorities on questions concerning health. In the *Dietetic and Hygienic Gazette* for May are two editorial articles dealing with the matter of bathing or washing. The first upholds ordinary cleanliness, in fact is in consonance with modern views as to the healthfulness of cleanliness. The second article on the subject quotes the opinions expressed a few weeks ago by Sir Almroth Wright in which he places himself on record as no hard and fast believer in the virtues of washing, fresh air, and physical exercise. So far as washing is concerned he boldly states that "a great deal of washing increases the microbes of the skin, so I do not think cleanliness is to be recommended as a hygienic method." There is something in Wright's argument, undoubtedly, and washing, of course, is by no means a *sine qua non* in the preservation of health. There are very many extremely healthy persons in this country and in all countries who wash but seldom and live to an old age. The agricultural laborer of England seldom or never washes his whole body and his ablutions generally may be described as perfunctory, yet he is physically a splendidly healthy animal. Bathing is a decent, pleasant, and esthetic custom, but not absolutely necessary to the preservation of good health. With the other assertions of Wright that fresh air and physical exercise are not essential to health, issue may be taken. Perhaps he meant to deprecate the intense enthusiasm of the middle class Britisher for fresh air and exercise, in the same spirit as Rudyard Kipling severely criticised the love of sport and games carried to an absurd extent by the modern well to do inhabitant of the British Isles.

It must also be borne in mind that Wright, like Bernard Shaw, is an Irishman and may have said such things, as Shaw often makes remarks with his tongue in his cheek, in order to take a rise out of the dense Saxon. Also ordinary statements do not attract the attention of or arouse the Briton, so that extravagent assertions must be made to take him out of his somewhat apathetic altitude. It is to be hoped that owing to Wright's views on bathing the Englishman will not lapse so far as washing is concerned, for, after having established a world-wide reputation as the persistent wooer of the matutinal cold tub, it would be almost a national disaster if he were to be dissuaded from the time-honored ordeal by the ill-considered words of a possibly irresponsible although deeply scientific Celt.

International List of the Causes of Death.

Taking the United States as a whole, the registration of births and deaths has been greatly neglected. Until 1880 the only States enforcing laws compelling returns of the causes of death were Massachusetts and New Jersey. These have gradually been added to until at the present time eighteen States, the District of Columbia, and fifty-four cities in non-registration States have passed laws or ordinances requiring the attendant physician to report the cause of death before the interment of the body. As the matter now stands we have about 55 per cent. of the total population of the continental United States represented in the registration area. As the registration of vital statistics is universally admitted to be the true foundation upon which the science of preventive medicine and sanitation must be built, it is absolutely essential to have a uniform system of classification in order to derive the greatest benefit from a study of the published reports. A world-wide recognition of this fact was responsible for the calling of an International Commission for the second decennial revision of the Classification of Diseeases and the Causes of Death by the government of France at Paris in July, 1910. The United States was represented at this international meeting by a Census Commission, and as a result we now have the opportunity to participate in the use of a common nomenclature of causes of death with all English-speaking and Spanish-speaking nations of the globe, besides Belgium, France, Holland, Japan, and many other countries. The Census Bureau has made it possible for every physician to aid materially in the scientific compilation of vital statistics by the publication of a vest-pocket edition of the International List of the Causes of Death. This has been freely distributed to the profession throughout the United States, and as a result it is to be hoped that all death certificates may now conform to a common nomenclature.

Inebriety in the Parent and the Child.

Many men of note in the British medical world have expressed opinions recently as to the question whether the drinking habits of a parent injuriously influence the health of the child. Among the physicians whose views on such a subject are especially

valuable. Dr. Harry Campbell stated that *a priori* considerations lead to the conclusion that the effect of parental intemperance upon the offspring is less than many people are disposed to imagine. The argument is often made that the constant soakage of the reproductive elements in an alcoholized plasma necessarily injures them and thus interferes with the normal development of the new being arising within them. The fact, however, notes Campbell, must be borne in mind that germ and sperm are peculiarly resistant to outside influences. That no one can pass through life with a constantly normal blood is obvious. Every passing illness tends to affect the blood injuriously, and were the reproductive cells readily injured by noxious plasma, the effects accumulating from generation to generation would soon result in racial extinction. The same result would follow injurious somatic impresses were acquired characters inherited. The effects of injuries to tissues if they were inherited would in a few generations accumulate to a degree incompatible with life. Their non-hereditability enables each individual to start life with a clean sheet. Campbell concludes that while chronic alcoholism produces profound individual deterioration, it does not cause racial deterioration. It does, however, bring about racial effects, but this far from being injurious is beneficial, for drunkenness tending as it does to fasten upon congenital degenerates, hastens their elimination, which from a racial point of view is an advantage. Archibald Reid, who is perhaps the greatest British authority on the principles of heredity, holds somewhat similar views to those quoted above.

Plague and Its Possible Spread.

In these days we are, perhaps, somewhat too apt to plume ourselves on the belief that in our advanced stage of civilization it is impossible that an epidemic of plague can ever again devastate the western world. That such an event is probable is true, but that it is impossible the sanitary authorities are by no means certain. Prof. W. I. Simpson of the London School of Tropical Medicine writes in the *Practitioner,* May, 1911, in by no means an optimistic mood regarding the state of affairs in Northern China. He points out that the fact that the disease is marked by the absence of buboes and presumably, therefore, the majority of cases are of the pneumonic type, is in itself of sinister significance. Another disturbing feature of the Manchurian epidemic is that as soon as the malady increased, crowds of people who had been working in the district hastened to leave and return to their homes, and thus were the means of spreading infection over a vast area. Thus there are two factors of the present epidemic calculated to excite alarm, the type of the disease and the expanding area of infection. According to Simpson, should the plague in Northern China acquire in the pneumonic form the dimensions which the disease in the bubonic form has in India, then a pandemic must be almost inevitable. The writer goes so far as to say that if the epidemic is an expanding plague and continues to be of the pneumonic type, then no organization at present in China can stop it. The pneumonic type is especially dangerous, not only on account of its acutely infective character, but because an infected individual may present no obvious symptoms. The sufferer may not appear to be very ill, but in a few hours he will be dead. Simpson says that the methods of prevention for Europe must chiefly depend on excellent sanitary organization, and the erroneous impression now held by many that plague is essentially an Asiatic disease and that Europeans are immune should not be allowed to prevent timely precautionary measures.

News of the Week.

Health of the Canal Zone.—The report of the Department of Sanitation of the Isthmian Canal Commission for April, 1911, gives the total number of deaths from all causes among employees as thirty-eight, of which twenty-six were from disease and twelve from violence. The death rate for the month in this and previous years was as follows:

1905	10.95
1906	30.00
1907	38.67
1908	7.77
1909	8.57
1910	13.04
1911	9.38

The annual average death rate per thousand in the cities of Panama, Colon, and the Canal Zone, including both employees and civil population, for the month of April of each year was as follows:

1905	39.29
1906	39.06
1907	40.97
1908	20.04
1909	16.77
1910	19.73
1911	17.74

Divided according to race, the annual average death rate per thousand from disease among employees was, for whites, 2.85, for blacks, 7.67, a general average of 6.42. The deaths from the principal diseases were as follows: Chronic nephritis, 3; dysentery, 1; malarial fever, 1; measles, 1; lobar pneumonia, 9; tuberculosis, 3; typhoid fever, 1, leaving seven deaths from all other diseases. The epidemic of measles mentioned in the previous reports continued during April, but was on the decline. No cases of yellow fever, smallpox, or plague originated on or were brought to the Isthmus during the month. In Panama the mortality among children under five years of age continued high during the month, the chief causes being gastro-enteritis, tuberculosis, and malaria. The regular work of sanitation has been carried on vigorously, 900 feet of new ditches being dug. The recent heavy rains showed that the system of drainage constructed in the swamp during the dry season will prove effective.

Floating Hospital.—The floating hospital Helen C. Juilliard of St. John's Guild will make its first trip for the season on July 5, carrying patients to and from the Seaside Hospital at New Dorp, Staten Island, which was opened on June 5.

Hospital May Be Sued.—The Court of Appeals of New York has reversed the decision of the lower courts and his decided that the Presbyterian Hospital of New York must defend a suit for $50,000 brought by Jane Darcy because the hospital authorities refused to give up her son's body immediately after death and allowed an autopsy to be performed against her wishes. The plaintiff's son died in the hospital on October 31, 1906, and when permission for an autopsy was refused the coroner was notified and one of his physicians was allowed to perform the autopsy in the presence of the hospi-

tal surgeons. As the hospital has not yet shown that there was anything unusual or suspicious in the manner of death, the performance of the unauthorized autopsy may be, the court holds, regarded as a misdemeanor, and the plaintiff may maintain an action for damages because of her wounded feelings.

Registration of Tuberculosis Cases.—The workings of the law passed in New York State in 1908 requiring the reporting of all cases of tuberculosis are shown in a statement issued recently by the National Association for the Study and Prevention of Tuberculosis, the following table giving the number of reported living cases and the number of deaths in Greater New York:

	1907	1908	1909	1910
Reported cases....	2,756	3,310	6,908	5,957
Deaths	5,410	5,449	5,351	5,357

The effect of the law has, therefore, been to increase largely the number of reported cases in comparison with the number of deaths. Similar reports of living cases of the disease are now required in twenty-five States.

Infants' Milk Stations.—The organization of an Association of Infants' Milk Stations of the Borough of Manhattan has recently been announced. The association, which includes all the agencies engaged in this charity, aims to prevent overlapping of the work and duplication of effort, and to provide for fuller cooperation and publicity and the establishment of similar systems of records. There are at present sixty-five milk stations in New York and this number will probably increase during the summer. It is believed that this association will do much to strengthen the efficiency of what is already one of the most important features in the campaign for the reduction of infant mortality.

Yale Medical School.—A gift of $20,000 to the Yale Medical School for the purpose of aiding original research in the study of diseases was announced on June 9. The donor is Prof. Francis E. Loomis of London, son of the late Elias Loomis, for many years professor of astronomy in Yale University. The gift of $10,000 toward the endowment of the university clinic was also announced.

Home for Cripples.—The Robins' Nest, a home for crippled children at Tarrytown, N. Y., was formally opened on June 8. The Nest already accommodates twenty-two children, most of them from New York City.

University of Illinois.—Degrees were conferred upon ninety-four graduates of the College of Physicians and Surgeons, the medical department of the University of Illinois, Chicago, at the annual exercises on June 4 by President Edmund J. James of the university.

Sprague Memorial Institute.—Announcement has been made of the organization of the Otho S. Sprague Memorial Institute, Chicago. The institute will be devoted to medical research, and Dr. H. Gideon Wells, associate professor of pathology in the University of Chicago and Rush Medical College, has been elected director. Dr. Frank Billings, Dr. James B. Herrick, Dr. Joseph L. Miller, Prof. E. R. LeCount, Prof. Ludwig Hektoen, Prof. E. O. Jordan, and Prof. Julius Stieglitz have been appointed an advisory council. The work will be carried on in cooperation with existing institutions and the institute will have control over a number of beds in the Presbyterian Hospital for the investigation of certain diseases.

McGill University Medical School.—The opening of the new building for housing the Faculty of Medicine of McGill University, Montreal, occurred on June 5, His Excellency Earl Grey presiding at the ceremonies. The building takes the place of the one which was destroyed by fire in April, 1907, and is largely the gift of Lord Strathcona, whose donation of $450,000 made possible the erection of the entire plant, including the museum, at one time. Fireproof construction has been used throughout the building, which is the largest one in the university group, having a frontage of 268 feet, with wings running back 171 and 114 feet respectively. In the rectangle thus formed the medical museum building is situated.

Yellow Fever at Kingston.—A case of yellow fever was reported at Kingston, Jamaica, on June 5.

Anti-Typhoid Vaccination.—Secretary of War Stimson, who has been much interested in the work of the medical corps of the army, set an example to his subordinates on June 6 by voluntarily submitting to vaccination against typhoid fever. All the officers and men stationed at the maneuver camps have already been vaccinated by order of the Department of War and the results have been most satisfactory.

College of Physicians and Surgeons.—Seventy graduates received the degree of doctor of medicine at the annual commencement exercises of the college held at Columbia University on June 7, the Hippocratic oath being administered by Prof. John G. Curtis, retired.

At a recent meeting the trustees of Columbia University announced the receipt from an anonymous donor of a gift of $33,133 for the William T. Bull Memorial Surgical Research Fund.

New York University.—The degree of doctor of medicine was conferred upon sixty-eight graduates of the New York University and Bellevue Hospital Medical College at the commencement exercises held on June 7. The Grover C. Arnold prize in surgery was awarded to Isador Samuel Faust of New York, and the Valentine Mott medals to Isador Blau, Luigi Celano, and Alexander Aisman, all of New York.

Dr. Charles Francis Stokes, Surgeon-General of the United States Navy and a graduate of the College of Physicians and Surgeons in 1884, received the honorary degree of doctor of sciences from Columbia University at the commencement exercises on June 7.

School of Public Health.—The New York State Senate on June 8 passed a bill introduced by Assemblyman Bush appropriating $10,000 to permit State Commissioner of Health Eugene H. Porter to have established at Cornell University a State school of sanitary science and public health.

Street Car Accidents.—During the month of March, 1911, the number of passengers injured on the subway, elevated, and street car lines was 1,840, as against 1,965 during March, 1910, although the number of passengers carried increased about 2.5 per cent. Of these seventeen were killed and 134 seriously injured.

Stray Dogs.—Commissioner Lederle, of the New York City Department of Health, has agreed to cooperate with the Society for the Prevention of Cruelty to Animals in ridding the city of the stray dogs which are a menace to public health during the summer. The health department will give its complaints to the society, which will then send out for the dogs.

Smallpox in New York.—The New York State

Department of Health in the regular monthly bulletin for the month of April, issued on June 9, reports that smallpox has made its appearance in several localities throughout the State. Two cases of the disease were reported in Albany on June 8.

Vital Statistics.—During the first four months of 1911 there were 53,400 deaths in New York State, as against 51,630 for the first four months of 1910. March in both years had a mortality never before reached in this State except in 1904, the month of March in these three years being the only month in which the number of deaths exceeded 14,000. In April, 1911, there was a decrease of 900 deaths as compared with the preceding month, while in April, 1910, the decrease was 1,300, showing that the causes of sickness and death which were so marked in the early months of these two years have persisted longer into this spring than into last.

The de Roaldes Prize.—The object of this prize is to advance the sciences of laryngology and rhinology in the United States and Canada. The prize will consist of a medal, to be known as the de Roaldes prize medal, and to be awarded triennially for the best essay on some subject relating to laryngology or rhinology. The competition will be open to practitioners in regular standing of the United States and Canada not members of the American Laryngological Association. The essays must be in English and typewritten. They must be placed in the hands of the secretary of the American Laryngological Association on or before a previously announced date, the customary measures being taken to prevent disclosure of the author's name. A committee of three will be appointed by the president of the American Laryngological Association to serve as judges. The committee will give preference to essays offering new suggestions of practical value, especially if growing out of original work. The successful essay will be published in the Transactions of the American Laryngological Association, but the author will be allowed to publish the essay at his discretion as soon as the prize shall have been awarded.

Steamships in Quarantine.—Both the French liner *La Bretagne* and the Cunarder *Carpathia* were held in Quarantine for several hours when they reached New York on June 5. The *Carpathia*, which came from Naples and other Mediterranean ports, brought in fifty cases of measles, while *La Bretagne* was detained because of a case of smallpox among the steerage passengers. All of the sick were transferred to hospitals.

Charitable Gifts.—The Bridgeport Hospital of Bridgeport, Conn., receives a bequest of $5,000 for the endowment of a free bed for the exclusive use of colored residents of the city under the will of the late Mrs. Caroline C. Thompson of New York, a daughter of the late P. T. Barnum.

The Tri-State Chapter of the Graduates of the College of Physicians and Surgeons of Baltimore has been organized to include the graduates of that college residing in New York, New Jersey, and Connecticut. At a meeting held May 27 at the home of Dr. H. B. Sheffield the following officers were elected: *President*, Dr. W. E. Fitch (1891), New York; *First Vice-President*, Dr. Wm. J. A. O'Hara (1893), Bridgeport, Conn.; *Second Vice-President*, Dr. John H. Carman (1881), Plainfield, N. J.; *Secretary*, Dr. J. G. Callison (1909), 601 West 135th street, New York; *Treasurer*, Dr. H. B. Sheffield (1895), New York; *Librarian*, Dr Arthur C. Palmateer (1906), New York; *Executive Committee*, the above officers, with Dr. Frederick M. Luther (1880) (chairman), New York; Dr. Otto C. Thompson (1906), Cassville, N. J., and Dr. D. J. McCarthy (1907), Bridgeport, Conn.

Louisiana Railway Surgeons' Association.—The railroad surgeons of Louisiana recently formed an association under this name, electing the following officers: *President*, Dr. H. B. Gressner, New Orleans; *Vice-Presidents*, Dr. J. B. Guthrie, New Orleans; Dr. S. L. White, Shreveport, and Dr. H. P. Wilson, Shreveport; *Secretary*, Dr. J. D. Martin, Shreveport; *Treasurer*, Dr. D. W. Kelly, Mansfield.

The Ausin Flint Medical Society will hold its semi-annual meeting at Clear Lake, Iowa, on July 11 and 12.

Louisiana State Medical Association.—At the annual meeting of the society held at Shreveport on June 1 the following officers were elected for the ensuing year: *President*, Dr. R. O. Simmons, Alexandria; *Vice-Presidents*, Dr. J. C. Willis, Shreveport; Dr. B. A. Ledbetter, New Orleans; Dr Otis Edgerton, Arcadia; *Secretary*, Dr. Joseph W. Martin, New Orleans; *Treasurer*, Dr. C. C. Bass, New Orleans.

Connecticut State Medical Society.—At the 119th annual meeting of this Society, held in Hartford May 24 and 25, the following officers were elected: *President*, Dr. John G. Stanton of New London; *Vice-Presidents*, Drs. D. Chester Brown of Danbury and Robert C. Paine of Thompson; *Secretary*, Dr. Walter R. Steiner of Hartford; *Treasurer*, Dr. Joseph H. Townsend of New Haven. The next annual meeting will be held in New Haven on May 22 and 23, 1912.

Harlem Medical Association.—At the annual meeting of the Harlem Medical Association, New York, held recently, the following officers were elected: *President*, Dr. Thomas F. Reilly; *Vice-President*, Dr. Carl Goldmark; *Secretary*, Dr. F. C. Heckel; *Treasurer*, Dr. Seymour Oppenheimer; *Trustees*, Dr. Frank C. Yeomans, Dr. John Remer, and Dr. Martin Cohen.

American Pediatric Society.—At the annual meeting of the society held at Lake Mohawk, N. Y., May 30 to June 1, 1911, the following officers were elected: *President*, Dr. Augustus Caillé of New York; *Vice-President*, Dr. P. J. Eaton of Pittsburg; *Secretary*, Dr. Samuel S. Adams of Washington; *Treasurer*, Dr. Charles H. Dunn of Boston; *Recorder and Editor*, Dr. L. E. La Fetra of New York; *Member of the Council*, Dr. John Howland of New York; *Member of the Executive Committee*, Dr. A. Jacobi of New York; *Alternate*, Dr. J. P. Crozer Griffith of Philadelphia. Next place of meeting, Hot Springs, Va., May 29-31, 1912.

Meeting of the University of Pennsylvania Alumni.—A banquet of the University of Pennsylvania Alumni will be held at the Hotel Alexandria, Los Angeles, on Tuesday, June 27. All "Pennsylvania Men" are requested to notify Dr. T. Perceval Gerson, suite 1011-1012 W. P. Story Building, Los Angeles, Cal., of their intention to attend the banquet, and if possible should send check or money order for amount of plate ($5). Addresses will be made by a number of the graduates of "Old Penn" and an enjoyable time is promised.

The Prevention of Poliomeyelitis.—The following circular has been addressed to health authorities and boards of health by the American Orthopedic Association and the American Pediatric Society: "Anterior poliomyelitis is, so far as known,

a communicable disease, being communicated from one patient to another and also by means of a third person. It occurs in epidemics and tends to spread along the lines of greatest travel. There is reason to believe that it is prevented from spreading by quarantine, and with the very great prevalence of the disease in the summer of 1910 it is the opinion of this committee that it is essential that it should be made a reportable disease in all States in order that its presence may be detected and its spread guarded against. Of particular significance are the so-called abortive cases, where indefinite ailments occur in children in communities where frank paralysis also exists. These abortive cases of infantile paralysis are undoubtedly a source of infection and their record and study is of much importance. In a community where cases of infantile paralysis occur cases of illness with sudden onset of fever and meningeal symptoms should be closely watched and regarded as possibly infectious. In such cases even recovery without paralysis does not establish the fact that the case was not abortive infantile paralysis. All cases of infantile paralysis should be strictly quarantined, sputum, urine, and feces being disinfected, and the same rigid precautions being adopted as in scarlet fever. This quarantine should, in the opinion of the committee, last for four weeks in the absence of definite knowledge as to when the infection ends. Children from infected families should not be allowed to go to school until the quarantine is abandoned. The transportation or transfer of acute cases in public conveyances should be strictly forbidden. It would be very desirable to adopt provisional quarantine measures in suspicious cases in a community where an epidemic prevails. The report of all cases of infantile paralysis to the public health authorities should be enforced by law, and all deaths from this cause should be properly described and registered. A careful study of epidemics by public health authorities is strongly advised. (Signed) Robert W. Lovett, M.D., chairman; Henry Koplik, M.D., H Winnett Orr, M.D., Irving M. Snow, M.D., secretary.

Obituary Notes.—Dr. Joseph Price of Philadelphia died on June 6 of appendicitis, at the age of fifty-seven years. He was a graduate of the medical department of the University of Pennsylvania in 1877, a former president of the American Medical Association, a fellow of the College of Physicians of Philadelphia, and a member of the American Association of Obstetricians and Gynecologists and of the Pennsylvania State and Philadelphia County Medical Societies. He was one of the founders of the Gynecean Hospital of Philadelphia and was a widely known gynecological surgeon.

Dr. Thomas Davis Strong of Westfield, N. Y., a graduate of the medical department of the University of Buffalo in 1851, a member of the American Medical Association, and of the New York State and Chautauqua County Medical Societies, died at his home on June 6, aged eighty-nine years.

Dr. Michael T. Prendergast of Philadelphia died at Ocean City, N. J., on June 3 at the age of fifty-eight years. He was born in Ireland and was graduated from the medical department of the University of Pennsylvania in the class of 1882. After engaging in the practice of his profession in the city of Easton, Pa., he removed to Philadelphia, where he had been in practice since. He was consulting physician to St. Joseph's Hospital.

Dr. Daniel M. Dill of Newark, N. J., a graduate of the department of medicine and surgery of the University of Michigan in 1867, a member of the New Jersey State and Essex County Medical Societies, and for ten years superintendent of the Essex County Hospital for the Insane, died at his home after a long illness on June 9.

Dr. William Delker of Philadelphia, Pa., a graduate of the Jefferson Medical College, Philadelphia, in 1884, died at his home on June 1, aged sixty years.

Dr. Charles H. Hamilton of Dubuque, Iowa, a graduate of the Rush Medical College, Chicago, in 1875, and a member of the American Medical Association and the Iowa State and Dubuque County Medical Societies, died at his home on May 28, of blood poisoning, aged sixty-two years.

Dr. Clarence E. McFall of Corona, Cal., formerly a practising physician in Peoria, Ill., a graduate of the Louisville Medical College, Kentucky, in 1891, was accidentally killed on May 24, aged fifty years.

Dr. T. G. Greer of Roswell, Ga., a graduate of the Atlanta Medical College, Georgia, in 1869, died at his home on May 21, aged seventy-four years.

Obituary.

CARL BECK, M.D.,

NEW YORK.

Dr. Carl Beck, professor of surgery in the New York Post-Graduate Hospital and Medical School, died at his summer home in Pelham Heights, New York, of pneumonia, on June 8. Dr. Beck was born in Neckargemünd, Germany, on April 4, 1856, and was graduated in medicine from the University of Jena, Germany, in 1879. He came to this country twenty-nine years ago and had since practised continuously in New York. He was president and visiting surgeon of St. Mark's Hospital from 1886 until his resignation a few months ago, and visiting surgeon to the Post-Graduate Hospital since 1890. He was formerly president of the Therapeutical Society, the Society of Medical Jurisprudence, and the German Medical Society, and was a member of the American Medical Association, the New York Academy of Medicine, the New York State and County Medical Societies, and the American Urological Society, and a corresponding member of the Urologisches Gesellschaft, the Münchener medizinische Gesellschaft, and the Royal Medical Society of Buda Pesth. Dr. Beck had written largely upon medical matters and was also the author of "Der Schwedenkonrad," a novel of the Neckar Valley, and of "Sonnenblicke vom lateinischen Amerika," a book of travels in the West Indies and the Spanish Main.

Correspondence.

MEDICAL EXPERT TESTIMONY.

To the Editor of the Medical Record:

Sir: In the interesting discussion of the subject of Medical Expert Testimony which took place on May 18 at the Academy of Medicine, very little new light was shed on a dark chapter of medical history. Perhaps the best proposition was that made by the learned judge who read the principal paper of the evening. That proposition, which, he told us, has twice been embodied in a bill which has twice been defeated in the Senate at Albany, relates to the appointment of sixty medical experts by certain judges

in each judicial district. But does not the success of this plan depend upon the knowledge of the medical market by these judges, and their integrity and courage? Who appoints the judges? In the crass ignorance of detail of the mere nomenclature of the courts (to which I think most doctors must plead guilty) by which I am afflicted, I confess that I do not know how these judges obtain their commission. Furthermore, I confess I do not know how many courts are superior to the Supreme and how many are inferior to the Superior, or just what judges could be empowered to select the sixty experts in this city if the defeated bill were successful. But if the judges were to select these experts on the same plan, or lack of plan, on which they select their own physicians, would the standing of the experts be likely to be improved?

Setting aside the cases where medical experts are openly selected for other reasons than their experience, skill, and high principles, is it not true that they are at present selected in much the same way and for much the same reasons that doctors in general are selected by their patients?

I contend that the average among the intelligent, successful members of the community select their doctors upon principles which they would never think of applying in the selection of any other business agent. For example, in almost every other vocation in life a *sine quâ non* is apt to be sobriety and honesty. You would never think of selecting anyone, from a cook to a college president, who was not possessed of both of these characteristics. How often have I heard otherwise rational beings say things like this: "I would rather have A. B., drunk, operate on me than any other doctor, sober."

How common has been the spectacle of people flocking in large numbers to the office of a popular specialist whose fellow specialists refused to have professional relations with him, either in the special societies or in the consulting room, because of some moral obliquity to which they had not become quite callous?

Is not the matter of the selection of medical experts at present subject to a similar mental idiosyncrasy?

Has not the commercial spirit so thoroughly entered the medical profession that skill in advertising already counts for more than scientific attainment and experience? How can these judges intelligently weigh the merits of several thousand medical men in a community like this; and would they be likely to apply better standards than those to which they resort in the selection of their family doctors?

To me the only hope for the improvement of the standing of the medical expert lies in the education of the community, in the hope that one of these days doctors may take rank with other agents who are employed for the performance of certain more or less important duties to their patients and to the public, agents whose selection is to be governed by the same rules of common sense that are applied in the selection of other equally important agents. Doctors no longer deal in magic and the black arts, and do not cease to be men when they become doctors, and are not to be separated from men in the mental processes that govern their selection by others.

George L. Peabody, M.D.

New York.

Membranous Enteritis.—Czylharz reports four cases in which this disease followed typhoid fever. In none of the cases was there a history of constipation and nervousness.—*Archiv für Verdauungskrankheiten.*

A SOURCE OF ERROR IN THE DIAZO REACTION.

To the Editor of the Medical Record:

Sir: In your issue of April 1, page 583, appears an interesting note on "Source of Error in the Diazo Reaction." This test is of such value in the diagnosis of typhoid fever, and of such prognostic use in tuberculosis, and the administration of phenolphthalein is so frequent that the combination must often occur. The true diazo reaction depends on the color change in the foam, after shaking, not on the color imparted to the liquid. After reading your article I prepared a solution of two drops of 1-30 phenolphthalein in 5 c.c. of distilled water, which I used (instead of urine) in making the diazo test. The crimson color was, of course, imparted to the liquid, but the foam produced by shaking was, after standing ten seconds, clear—not colored. Whether this will hold good when the phenolphthalein is ingested I do not know. There should be further investigation.

Jno. C. King, M.D.

Banning, Cal.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

THE STATE INSURANCE SCHEME—POSTOPERATIVE LUNG COMPLICATIONS—RADIUM IN MALIGNANT GROWTHS—CANCER HOSPITAL NEW RESEARCH LABORATORIES—OBITUARY.

London, May 26, 1911.

The approval which the State Insurance proposal at first evoked is being rapidly dissipated. The attempt of the Government to rush the bill through is condemned in all quarters. They actually wanted to force the second reading through this week but have been compelled to give Monday to further discussion. As if the bill itself were not complex enough a White Paper, of 42 pages, was issued, containing the actuarial calculations on which Mr. Lloyd George had based it, and he wanted the House to pass the second reading the next day. To many such haste seemed a strong reason for delay. Chambers of commerce, the friendly societies, and other organizations insisted on the necessity of time to consider such wide-reaching proposals. But it is the position as to the profession which will most interest your readers. That is one of decided dissatisfaction on the whole, partly inspired by misgivings as to what will be the ultimate form adopted to secure their concurrence and partly by their past experience of the friendly societies. Medical agents announce that the proposal has rendered practices quite unsalable and should this be only a temporary result it must inflict hardship on a number of persons. But it is not only those who take club practices who have doubts and fears. As Sir A. Pearce-Gould pointed out at a meeting of the Middlesex Hospital, if the bill became an act many patients would be taken charge of by the State and generous donors might be inclined to cease subscribing. There was, too, the danger of passing under State control, which would be a bad thing for the hospitals The interests of surgery were also at stake. If any change were to benefit the community it must be one in which the whole medical profession could work, heart and soul.

The General Medical Council has met and appointed a committee to watch the bill, report and receive communications.

Dr. W. Pasteur's oration, briefly chronicled in my last, was a valuable contribution to our knowledge of a subject which has perplexed observers from early times and is still a source of anxiety to every surgeon. He dealt with pneumonia or bronchpneumonia occurring after operations, not with all of these, but in those in which the peritoneal cavity has been opened, or the peritoneum severely handled in the course of operations in its immediate neighborhood, *e.g.* in those on the kidney. He said this limitation was not merely arbitrary for it groups together almost every case of postoperative pneumonia. These complications occur more frequently in hospitals than in private practice and the author believed that some, especially lobar collapse, which may develop insidiously, are sometimes overlooked or wrongly interpreted. Not many years ago the anesthetic was generally blamed by the surgeons. But this view is no longer tenable. It is true that ether may cause bronchial irritation, over-secretion, and cough, and it is conceivable that it might excite inflammation. But if this last occur we must look for further cause and the aspiration of saliva and mucus, carrying pathogenic organisms, supplies one. The conditions of hospital practice (state of mouth, impurity of air, low resisting power of patients, etc.) may partly account for the more frequent occurrence.

Deflation of the lung from any cause predisposes to inflammation, and abdominal section, especially above the umbilicus, seriously interferes for several days with expansion and aeration of the bases. Indeed inhibition may be so excessive as to deprive the affected lung of air—reflex lobar collapse. This differs from patchy or lobular collapse. A few years ago Dr. Pasteur felt that perhaps massive collapse from reflex inhibition of the diaphragm might account for some of the perplexing lung conditions that sometimes follow abdominal section. He has had good opportunities of studying the matter and mentioned cases which convinced him that this is so—one was found post-mortem which for the first time disclosed collapse of the bases, such as previously had only been met with from paralysis of the diaphragm. This collapse then is beyond doubt the direct result of the paralysis. But probably it may also be brought about by reflex inhibition.

Clinically this massive collapse may simulate and be mistaken for pneumonia. It may come so suddenly as to suggest pulmonary embolism. On the other hand, it may set up scarcely any symptoms and be missed unless looked for. The conclusive origin of it is the displacement of the heart's apex beat toward the affected side. In a well-marked case the whole of the lung may be thrown out of action temporarily, the signs extending from base to apex with decreasing intensity. It is not possible to say what proportion of cases of post-operative pneumonia begin as massive collapse. To estimate that we want to know the position of apex beat and the condition of the bases just before every abdominal operation, and these points must be carefully determined for several days following.

The conclusions drawn from his studies by the orator are that deflation of the pulmonary bases from inhibition of diaphragmatic movement is an essential factor in the cause of post-operative pneumonia. The rôle of the anesthetic is quite secondary. He is convinced that a good deal can be done in preventing or alleviating these troubles but for this more accurate diagnosis is essential.

Mr. Mansell Moullin has given some account of his views on the treatment of malignant growths by radium to the Roentgen Society. His great experience as surgeon to the London Hospital (now consultant) enabled him to touch on many points concerning cancer and its treatment by this in contrast with other methods. He laid down that the action of radium is to kill the tissues immediately exposed to it, with the possible exception of vascular and connective tissues. But if the effect falls short of killing it lowers their vitality. A second exposure before recovery acts more intensely, is more destructive on this account, and is no proof of a cumulative effect which some have attributed to it. It is equally incorrect to speak of a selective action. Certain cells, mostly young and highly specialized cells, were peculiarly susceptible to it. This, he said, was because of slighter powers of resistance, not to a selective action of the rays. People did not talk of selective action of the sun's rays on blondes as compared with brunettes. The success of radium in malignant growths is due to the greater susceptibility of their cells, their quiet necrosis and removal, and the gradual substitution of connective tissue which in the absence of infective organisms becomes organized and does not contract as a scar does. The question of metastasis was treated as to the plan of introducing radium tubes into growths. The manipulation required was admitted to be very slight, but the very slightest was most undesirable, especially in soft, rapidly growing, malignant tumors. There was, said Mr. Moullin, no better method for setting up metastasis. Cutting into a tumor to verify diagnosis has long been abandoned for this reason. Radiation, therefore, should be directed from the circumference and the growth treated with the utmost gentleness. So scraping with a Volkmann's spoon before applying radium to get rid of outlying cells left was just as dangerous. Lately surgeons had recognized the necessity of never letting a cancer cell or blood coming near uninfected tissues in the course of operations. Dissemination would certainly result. As to the cases most suitable for a trial, clinical character was more important than microscopical appearances. Mammary cancer in a woman under thirty-five was not the same as at sixty. The prognosis was very different, whatever the treatment. Many sarcomata end in a few months, but he had seen some last for many years. Numerous other factors were involved of which little was known. Growths, so far as we could tell, identical in size, character, and locality might react to radium in an entirely different way. He had known it fail completely in rodent ulcer, the disease in which it is usually most successful. The factors which seemed to him of clinical value were slowness of growth and mildness of malignancy, and he instanced these as present in rodent ulcer, which grows very slowly, is small and superficial, the cells with slight resisting power. It was only when these conditions existed that success was to be had, for if a rodent ulcer had been irritated by ineffectual attempts at removal, or by septic infection, so that the margins instead of being sharply defined became swollen and hyperemic radium would not be likely to succeed.

With reference to the risk of dissemination, so forcibly stated by Dr. Mansell Moullin, I may remark that the system of cataphoresis has been tried in France with success. By this radium can be carried deeply into the tissues without breaking the

skin, and apparently the entire substance of a growth can be loaded with the remedy. The matter was mentioned at the Academy in March so you will know as much as we do about it. I therefore pass on. The view that the rays in full force kill the cells but in minor force debilitate them seems in accordance with what we know of other irritating or toxic substances, and certainly supports the recommendation to employ larger doses than have so far been advised. This view is also held by Dr. N. S. Finzi, who last year in a paper at the Royal Society of Medicine, laid down these four rules: (1) Treat thoroughly the whole tumor and the site of possible metastasis; (2) adequately filter the rays; platinum or lead 1 min. thick must be used; (3) use as large amount as possible; (4) maximum dosage. This he regards as very important. Dr. Fenzi adheres to the plan of sinking the radium tube into the tumor. He says it presents, as a rule, no difficulty, but care is required to insert it deeply enough to prevent it burning the skin. Apparently he does not fear that metastasis will occur.

Another paper touching this subject was read by Dr. Reginald Morton at the West London Society. Owing to the limited supply of radium he mostly relied on the *x*-ray tube. Neither, he found, controlled metastasis or recurrence. He agreed that the rays did not penetrate more than about 1 cm. thickness of tissue. He advocated immediate treatment after operation as a preventive of recurrence. In all cases where feasible operation should be done and followed up by applications. In inoperable cases he would try radium or or *x*-rays for at least a month. Even if this failed it made the patient more comfortable, bodily and mentally.

On Tuesday the Duke of Connaught opened the new research laboratories of the Cancer Hospital. They comprise facilities for chemical and physical research, a radioelectric room, a photographic department and an underground laboratory for working at a fixed temperature, a room for sterilization and for the preparation of culture media, and in addition to these, a good library, workshop, stores, and offices.

Dr. Peter Hume Maclaren, formerly examiner at the R. C. S., Edinburgh, and president in 1894, has died at the age of seventy-four. He qualified L.R.C.S. as early as 1857, and took the fellowship in 1868. He was also M.D. of the University of Edinburgh, 1857.

From India comes the announcement of the death on the 22nd inst. of Major Ch. J. Robertson-Milne, M.D., Aberd., I.M.S., of enteric fever, aged thirty-nine.

Dr. Wm. Daley, M.O.H. for Bootle, lost his life on May 20 in a motor launch accident in the Mersey. He took the two Edinburgh colleges in 1900 and the D.P.H. of the London colleges the following year. He held various appointments at Bootle.

Dr. E. M. Grace, the eldest of the three brothers who have held such a high position as cricketers, died on May 20, in his seventieth year, at Thornbury, Gloucestershire, where he practised. He had been Coroner for the western portion of Gloucestershire since 1875.

Dr. Alice Maud Thompson has died at Brighton, where she had practised since 1908. She was twenty-nine years of age and graduated at Edinburgh.

OUR CANADIAN LETTER.

(From Our Regular Correspondent.)

TO STAMP OUT THE DRUG HABIT IN CANADA—HOSPITAL COTS FOR WAR VETERANS—SMALLPOX SITUATION IN OTTAWA—APPOINTMENT OF SUPERINTENDENT OF GENERAL HOSPITAL, TORONTO, IN PLACE OF DR. J. N. E. BROWN, RESIGNED—NEW ISOLATION HOSPITAL FOR TORONTO—AMENDMENT TO THE CANADA MEDICAL ACT—TORONTO PROFESSOR FOR CALIFORNIA—FREE DENTAL CLINIC FOR TORONTO—FILTRATION PLANT FOR MONTREAL—LONDON PROFESSOR FOR MCGILL UNIVERSITY—SANATORIUM FOR TUBERCULOSIS IN SASKATCHEWAN—ESSAY COMPETITION IN TORONTO—MEETING OF THE CANADIAN SUPERINTENDENTS OF TRAINING SCHOOLS FOR NURSES AT NIAGARA FALLS.

TORONTO, May 30, 1911.

THE Dominion Parliament has under consideration the Opium and Drug Act, which defines noxious drugs as cocaine, salts or compounds, morphine, salts or compounds, opium in all its forms. Any person who sells, imports or manufactures, carries, or has in his possession these drugs is liable on conviction to a fine of $500, and costs, or a year in jail, or both. Any person smoking opium is liable to a fine of $50, or three months in jail, or both. Any person who without lawful excuse is found in any place in which opium is smoked or inhaled is liable to a fine of $100 or one month in jail, or both. The Canadian act sets forth that any person who deals in any drug and who gives, sells, or furnishes any drug other than to a duly authorized and practising physician, veterinary surgeon, dentist, or druggist, or who gives, sells, or furnishes any drug except upon a written order or prescription signed by a duly authorized physician or veterinary surgeon, or without the authority of the prescribing physician, etc., uses any prescription on more than one occasion, and neglects to keep proper records of such transactions shall be liable on conviction to a fine of $200, and costs, or three months' imprisonment, or both.

Physicians who sign prescriptions for the use of any drug prohibited under this act except for medical purposes shall upon conviction be fined $200, or given three months in jail, or both. The Ontario Act, passed about four years ago, prohibits the sale of cocaine, eucaine, stovaine, alpha or beta cocaine, opium, morphine, and salts of morphine except by qualified pharmacists, and then only upon the prescription of a qualified medical practitioner or dentist. The Province of Quebec has the most stringent statute in relation to these drugs. Under the act no person can deliver, give, or sell cocaine, alpha or beta cocaine, eucaine, morphine, or heroin, or any salts, compounds, or derivatives of such substances, or any prescriptions containing such substances or their salts or derivatives, except the duly licensed druggist, doctor, dentist, or veterinary registered under the laws of Quebec and then upon their written order. This prescription shall be dispensed only once and no copies thereof shall be given to any person. It has been found that in Canada since the reduction of saloons or hotels in some districts there has been a large demand for cocaine. Especially in Montreal is the cocaine habit on the increase, and hence the enactment of laws to strictly regulate the sale.

It is said that an effort is to be made to have

an act changing the regulations under which the South African veterans' relief fund is administered. Now the fund is only available to assist those veterans whose illness is directly traceable to the hardships of the Boer War, or to indemnify the families of those whose death is due to causes resulting from the war. The suggestion has been made recently that cots should be endowed in the leading hospitals of every Canadian city to be available for indigent veterans. The smallpox situation in Ottawa has been scarcely as serious as the public press suggested. The majority of the cases were of a mild type and the disease had gained some headway owing to the fact that the earlier cases were diagnosed as chickenpox. The local authorities, with the aid of the Ontario Board of Health, through its medical inspector, Dr. R. W. Bell, made a careful investigation, and with efficient quarantine of the cases in the isolation hospital and the sanitary police quarantine of exposed persons, all of whom had to be vaccinated, the outbreak has been practically extinguished. Dr. J. N. E. Brown, who had been superintendent of the General Hospital, Toronto, for several years, resigned the position some three months ago. Dr. Brown had been an excellent superintendent and his resignation was regretted. Dr. Clarke, superintendent of the Toronto Asylum for the Insane, has been appointed to the position left vacant by Dr. Brown. Dr. Clarke is said to be possessed of remarkable executive ability and well fitted for the somewhat arduous duties which, with the opening of the new general hospital, will fall to his lot. The Toronto Local Board of Health has decided to establish an isolation hospital for those suffering from scarlet fever, diphtheria, tuberculosis, and other infectious diseases on the outskirts of Toronto. An amendment to the Canada Medical Act has passed both houses of the Dominion Legislature, whereby a long step in the direction of Dominion registration has been made. Dr. J. E. Fitzgerald, lecturer in bacteriology in the University of Toronto, has resigned to accept the position of assistant professor of bacteriology in the University of California. It has been decided to establish a free dental clinic in Toronto. Montreal is to have a filtration plant at the cost of $2,000,000, with a capacity of 50,000,000 gallons per day. The Board of Governors of McGill University has appointed to the vacant chair of physiology Dr. R. N. Alcock, lecturer in physiology in St. Mary's Hospital Medical School, London, England, and vice-dean of the school. The province of Saskatchewan has voted $25,000 for an antituberculosis sanatorium. Toronto General Hospital's gold-headed cane competition for best essay on a medical subject, open to ex-house staff, was won by Dr. A. H. Caulfield. The fifth annual meeting of the Canadian Superintendents of Training Schools for Nurses took place at the Carnegie Library building at Niagara Falls, Ont., on May 25, and following day. There was a large attendance. Miss Mary Ard Mackenzie, R. N., superintendent of the Victorian Order of Nurses, Ottawa, presided, supported by Miss L. C. Brent, superintendent of the Hospital for Sick Children, Toronto, first vice-president, and Miss Stanley of the Victoria Hospital, London, Ont. Among the papers of interest read were "Schools of Nursing and the State," by Miss Annie W. Goodrich, R. N., inspector of the Nurses' Training School, New York State Educational Department. A paper on "Tuberculosis, Our Attitude Toward Its Prevention and Cure," was read by Mme. E. E. Fournier, R. N., superintendent of "Minnewaska," Gravenhurst, Ont. The technical meeting of the Canadian National Association of Nurses was also held at Niagara Falls, Ont., on May 25. In adopting a new constitution for the association it was decided that the meeting should be held annually.

Acute Inflammation of Long Bones, with Special Reference to Excision of the Diaphysis. R. G. LeConte.
The Action of Salvarsan upon the Wassermann Reaction. H. Fox.
The Early Diagnosis of Pulmonary Tuberculosis from the Standpoint of Physical and Fluoroscopic Examinations. J. A. Honeij.
The Neurology of Apraxia. G. V. N. Dearborn.
Accurate Optics. I. Hartshorne.

Acute Inflammation of Long Bones.—R. G. LeConte reviews 60 cases from which he draws the following conclusions: The mortality and extent of the necrosis following acute inflammation of bone depend not only upon the promptness of surgical interference, but also upon its thoroughness. Suppuration beneath the periosteum does not exclude an infection of the medulla, the presumption being that after three days the medullary cavity is also involved. Within seventy-two hours of the onset of the disease osteoperiostitis is localized usually in the cortex of the bone, and incision, disinfection, and drainage are sufficient to bring about a cure. If there is no marked diminution of the symptoms in twenty-four hours after incision and drainage, the medullary cavity should be opened. When the medullary cavity is opened and found healthy, the dangers from infecting it are slight. In the majority of cases osteomyelitis is due to a neglected osteoperiostitis. In operations after the third day, where systemic symptoms are pronounced, the medullary cavity should always be opened and the opening should be sufficiently long to expose the healthy marrow, and sufficiently broad and long to expose healthy bone. The author's mortality of 10 per cent. was directly due to delay in operation, and to inefficient surgery at the primary operation. He believes that the attempt should be made in the acute stage to remove at the primary operation all bone that is diseased. The periosteum in the acute stage of the disease will reproduce all bony defects, and delay means a greater number of operations, a greater destruction of bone, a greater likelihood of epiphyseal inflammation, a longer convalescence, and perhaps a higher mortality.

Salvarsan and Wassermann Reaction.—H. Fox states that the action of salvarsan upon the Wassermann reaction is in general analogous to that of mercury. The effect upon the Wassermann reaction is much less favorable than upon the clinical manifestations of syphilis.

Pulmonary Tuberculosis.—J. A. Honeij describes the methods employed in the detection of pulmonary tuberculosis in its earliest stage.

Neurology of Apraxia.—G. V. N. Dearborn defines apraxia as an incapacity for subjectively purposive movements, with conservation of the power of movement. In many voluntary movements spatiality seems to constitute the neural motor idea necessary for their coordination and muscular accompaniment, but in the movement of using an object space may be oftentimes only of secondary importance, although, one may presume, always underlying the cortical associations in its influence on the actual innervations. When the clinical observation of apraxia is regularly extended to cases or aspects presenting apraxic movements other than those concerning the use of small familiar objects, it can hardly be doubted that this important relationship of space-conditions will promptly appear.

Accurate Optics.—I. Hartshorne discusses the existing inaccuracy in optical production and the failure on the

part of many oculists to recognize the same. As regards cases of trial lenses, it is noted that oculists who have taken the trouble to go over their trial lenses to determine their accuracy have found them anywhere from 10 to 50 per cent. wrong. Oculists who use a mechanical axis finder and centering machine will admit that it is common to see patients wearing lenses that do not agree with their prescriptions. Opticians and oculists are both to blame, especially the oculists, since the responsibility to the patient is theirs. Absolute accuracy can be obtained when demanded and if the finished lens is properly inspected by the oculist.

Practical Treatment of Nervous People. J. J. MacPhee.
Tuberculosis of the Kidney in Women. H. N. Vineberg.
Acute Hematogenous Infections of the Kidney and Pyelitis of Pregnancy; Their Medical Treatment. L. Louria.
The Influence of Pregnancy on Diseases of the Eye. D. K. Shute.
Immediate or Deferred Operation in Tubal Pregnancy E. McDonald.
The Relation of Uterine Myomata to Heart Disease. J. A. McGlinn.
Acetone in Inoperable Cancer of the Uterus. A. Samuels.
Carcinoma of the Abdominal Wall in a Boy of Seventeen Years. J. P. Grant.
Note on the "Liquor Bellostii" Test in Paresis. G. S. Amsden.

Practical Treatment of Nervous People.—J. J. MacPhee states that his experience has been that every normal, encouraging influence and every helpful measure, whether it be the force of the physician's character or the sincerity of his purpose, a calming sedative or a bracing tonic, an invigorating exercise or a stimulating bath, a comforting diversion, or the consoling attention of a tactful nurse, constitute psychotherapy in so far as they bring hope and confidence and brighter prospects to the patient.

Renal Tuberculosis in Women.—H. N. Vineberg states that operative renal tuberculosis is more frequently met with in women than in men. Renal tuberculosis in women is seldom or never associated with tuberculosis of the genital organs. It is frequently overlooked in women and wrongly diagnosticated as catarrhal cystitis. From the fact that it is oftener unilateral in women than in men, and that it is seldom or never associated in the former with genital tuberculosis, the prognosis of operative interference is much better in women than in men. Nephrectomy for a tuberculous kidney in women is no bar to marriage or to bearing children.

Acute Hematogenous Infections of the Kidney.—L. Louria states that pyelitis of pregnancy belongs to this category. He believes that, in the presence of the acute hematogenous infections of the kidney, surgery, spurred on by its conquests in other fields of internal medicine, has wielded its knife with unwarranted freedom. A plea is made for the conservative methods of treatment whose success has been amply demonstrated in the author's experience. This success has been most conspicuous in the cases of pyelitis occurring in gravid women.

Pregnancy and Diseases of the Eye.—D. K. Shute states that albuminuric retinitis may exist for months without impairment of vision. It can exist for some time independently of, as well as in association with, symptoms of renal disease; also, independently of, as well as in association with, albuminuria. The presence of this retinal inflammation indicates a far advanced condition of the toxemia of pregnancy and indicates a very grave prognosis as to the life of the patient, for the kidney of pregnancy may be followed by chronic interstitial nephritis. As long as the albuminuric retinitis lasts there is danger of vision being irretrievably ruined at any moment and in any month.

Operation in Tubal Pregnancy.—E. McDonald puts no faith in Robb's contention that cases of tubal pregnancy should be treated expectantly from three to twelve days until there is recovery from hemorrhage and shock. Delay of an hour or so may sometimes be necessary to combat nervous shock: but delay of days is a policy which trusts to the patient's bleeding enough to lower her blood-pressure so that the bleeding will stop. Delay of days means the presence of adhesions, which increase the difficulty of operation and diminish the chances of recovery. Movement of the patient while bleeding seems to be very harmful. The best treatment seems to be immediate operation without precipitation.

Uterine Myomata and Heart Disease.—J. A. McGlinn states evidence does not sustain the view of the existence of a definite entity known as fibroid heart. Uterine myomata, occurring during middle and advanced life, are practically always associated with sclerotic heart lesions. These lesions are part of a general process and bear no relation to the fibroid. Many of the symptoms referable to the cardiovascular system found in fibroids are due to secondary anemia and occur just as frequently in anemia due to other causes.

Acetone in Inoperable Uterine Cancer.—A. Samuels states that acetone checks hemorrhages otherwise uncontrollable, and lessens discharges.

Carcinoma of Abdominal Wall.—J. P. Grant reports a case of this condition in a boy seventeen years old.

"Liquor Bellostii" Test in Paresis.—G. S. Amsden reports the results of his investigations which question the value of this test as a diagnostic measure. Liquor Bellostii consists of mercury nitrate dissolved in water slightly acidified with nitric acid. The test is done as follows: To a few cubic centimeters of acid urine, which has been boiled, add ten to fifteen drop of liquor Bellostii. The urine is then boiled again two or three times. In negative cases there is a heavy white or chalky yellow precipitate formed; in positive results the precipitate is gray, almost black, and the supernatant fluid is yellowish.

Problems of Gastrointestinal Surgery.—J. M. T. Finney concludes that problems of diagnosis present greater difficulties and are further from solution than those of treatment. Certain operative procedures, gastroenterostomy, *e.g.* have reached such a state of perfection that the ease of performance renders them a possible menace and calls for greater care in the proper selection of cases. The tendency to dogmatize on too little evidence in matters pertaining to the causation and treatment of the so-called functional intestinal neuroses should be discouraged, and a more scientific observation, interpretation, collection, and record of established facts substituted therefor. As a result of the knowledge gained by such comprehensive and exhaustive study of the intricate problems involved, it is not unreasonable to hope that, ultimately, in carefully selected cases, surgery may offer relief to this unfortunate group of gastrointestinal neurasthenics.

Pulmonary Tuberculosis.—W. V. Brem emphasizes the importance of physicians being trained in the highest degree in the diagnosis of this condition in its early stage.

Early Diagnosis of Pulmonary Tuberculosis.—W. H. Bell arraigns the greater part of the medical profession in not availing themselves of the numerous modern aids in the timely diagnosis of pulmonary tuberculosis.

Sending Away of the Tuberculous.—J. Walsh reports three cases illustrating the unsatisfactory results of sending tuberculous patients into the country, or anywhere where they cannot be under reliable medical supervision.

Malaria Simulating Appendicitis.—G. E. Henson reports a case in which the patient suffered from sudden severe abdominal pain, abdominal rigidity, vomiting, and special tenderness over the appendix. He was partially relieved by morphine. While all the subjective symptoms pointed to an appendicitis, the temperature curve made the author suspect malaria, and he examined for the malarial parasite, which was found.

Tumor or Abscess in Temporosphenoidal Lobes.—F. Kennedy, on the basis of ten cases that he has observed, sums up the following points in the diagnosis of these conditions. The symptom-complex of tumor in the right temporosphenoidal lobe in a right-handed person is as follows: Epileptiform convulsions, dreamy states, crude subjective sensations of smell or taste with or without involuntary reflex movements of mastication. Subsequent to major attacks; in most cases transient weakness of the left lower facial muscles, usually most evident on emotional expression; less often the left arm and leg temporarily paretic; left abdominal reflexes diminished or absent, deep, increased; the left plantar reflex may be of extensor and the right of flexor type. Bilateral papilledema usually of greater intensity on the right side. Reflex change and motor symptoms on the left side, at first merely postepileptic, but later become persistent phenomena. No word-forgetfulness after major attacks or at other times. No speech defect. The symptom-complex of tumor in the left temperosphenoidal lobe in a right-handed person is as follows: Difficulty in naming objects seen and recognized; later, word-forgetfulness in conversation; later, inapposite words and phrases, with instant recognition of mistake when made, but inability to prevent perseveration of verbal errors. Reading aloud and writing to dictation are well performed; spontaneous writing is poor. Epileptiform convulsions of varying severity and frequency; dreamy states or analogous pathological psychic conditions; crude subjective sensations of smell or taste, with or without involuntary reflex movements of mastication. Subsequent to major attacks; in most cases transient weakness of the right lower facial muscles, usually most evident on emotional expression; less often the right arm and leg temporarily paretic; right abdominal reflexes diminished or absent; deep, increased; the right plantar reflex may be of extensor and the left of flexor type. Bilateral papilledema, usually of greater intensity on the left side. Reflex change and motor symptoms on the right side at first are merely postepileptic, but later become persistent phenomena. The existence of hemianopsia would, of course, indicate precisely the side of the lesion.

Simple Living and the Normal in Medicine.—C. A. Penrose states that the physician should get a correct ideal of the normal man or woman, and should be able to recognize every deviation from it. He should watch for such in his patients and correct the aberrations. The author's experience has proved to him that the development of the muscle sense is the real problem of physical culture, and he points out the ways in which it can be cultivated. The boy scout idea, with its drills and exercises, he thinks, is an excellent one for the training of the young.

Tabes in the Negro.—E. M. Hummel states that, contrary to most persons' experience, he has seen, in several cases, full-blooded blacks suffering from tabes. Their usual exemption, in spite of immoral habits and syphilization, is due to general improvidence and lack of worry.

Vaccines in Otitis Media.—C. L. McDonald finds the use of autogenous vaccines of decided value in subacute cases of otitis media, but less reliable in chronic cases.

Vanadiumism.—W. F. Dutton describes this as a chronic intoxication caused by the ingestion or absorption of some forms of vanadium. Anemia is an early symptom. Dry cough, paroxysmal, and accompanied with hemorrhages, is a characteristic, and the victims are especially liable to tuberculosis. Emaciation, irritation of nose, eyes, and throat are always in evidence. Anorexia and symptoms of gastrointestinal irritation are common and albumin, casts, and blood are often present in the urine. Continuous action of the poison leads to fine tremors, headache, neuroretinitis and blindness, vertigo, hysteria, and melancholia. The drug is eliminated by the kidneys, but is also found in the feces, sputum, and saliva. The diagnosis is not difficult with a history of exposure, but accidental cases may give trouble.

Rectal Drainage in Appendix Abscess.—L. Davis reports two case in which this procedure was sucessfully employed and states that the method is available for large pelvic abscesses when the appendix is itself pelvic in position, and this can be determined only with approximate accuracy by the position of the mass.

Carbon Monoxide Poisoning.—W. Ravine states that the diagonis of illuminating gas poisoning is based on the history of the case and on the presence of coma with stertorous breathing, cherry-red color of the face and hands, and the spectroscopic analysis of the blood which demonstrates the presence of carbon monoxide hemoglobin.

Frontal Sinus Curette.—B. Higbee describes this instrument which he has devised for the purpose of enlarging the opening into the sinus, when drainage is insufficient.

Transillumination of the Mastoid.—E. Amberg recommends the method of Dintenfass as an aid in the diagnosis of conditions in the mastoid.

Hypodermic Injections.—F. T. Woodbury describes the technique he has used in the administration of typhoid vaccines to the members of a batallion of infantry and to the civilian population of an army post. An area on the arm is wiped with tincture of iodine. Using a glass-barreled syringe, the needle of the latter is dipped into the tincture of iodine; some of this is drawn up and then expelled, and then one dose of the vaccine is drawn up and then expelled. The syringe is now filled with the vaccine and the dose is injected into the iodine-painted area of the arm. The needle is then dipped into the tincture without any being drawn up, wiped off with gauze or cotton and is in condition for the next case.

Painless Mercurial Injections.—C. M. Watson has found that equal parts of quinine and urea hydrochloride 2 per cent., and mercuric chloride 2 per cent., both in distilled water, when heated to the boiling point and mixed, result in a clear solution. When mixed in a cold state a white precipitate is thrown down. The solution should be injected before it become cold, as later crystallization takes place. The author has found that this method insures a painless injection.

Acute, or Paroxysmal, Pulmonary Edema. A. E. Carver.
Notes on a Case of Gastroenterostomy After Fifteen Years. R. Bevan.
A Case of Pneumothorax Complicating Bronchopneumonia in a Child Aged Two Years. A. E. Sanderson.

The Exanthemata.—S. Phillips notes the diminishing mortality from these diseases. As regards scarlet fever, it is stated that this is infectious as soon as the rash appears. The amount of desquamation is not proportionate to the intensity of the rash. Rheumatism is quite a common complication and in children the affected joints may be painless. Cardiac complications of scarlet fever are rare. The renal complications are not now as severe as they formerly were, indicating a possible change in the type of scarlet fever. Measles is the most fatal of exanthems, causing three deaths to every one from scarlet fever. Whooping-cough alone approaches it. Lobular collapse of lungs is not uncommon in children with measles. The most reliable point in the differential diagnosis between measles and rötheln is the presence or absence of Koplik's spots. Pityriasis rosea may be mistaken for measles. Hyperpyrexia during the exanthemata in children is without grave significance, but in adults points to some local complication.

Cleft Palate.—J. Ulrich states that in the worst cases he operates if necessary on the processus alveolaris by the unilateral method with a Duplay's operation, by the double method after Bardeleben, and prefers to operate as early as possible. He operates subsequently for harelip at the age of from four to six months. The cleft in the palate will then, as a rule, diminish successively; but if it is, at the age of from two to three years, still very broad he abandons the patient to the prothesis treatment. There are cases in which a prudent squeezing of the jaws on the newly born child will make the operation easier later. In the other cases, where the cleft is narrower, he operates if necessary on the processus also as soon as possible; on the harelip at the age of from four to six months, and for the cleft palate he prefers Langenbeck's operation at the age of about two or three years, with a preference for the latter age.

The Pressor Bases of the Urine.—W. Bain states that the pressor bases are absent from the urine of children between ten and twelve years of age, and apparently begin to be excreted about the age of fourteen. A vegetable diet considerably reduces the amount formed. Eggs and fish reduce the quantity to some extent, but if chicken is taken the amount is but little less than one obtains on an ordinary mixed diet containing butcher's meat. The bases are either absent or considerably diminished in cases of high blood-pressure. Doubtless the diminution in some cases is partially attributable to low dietary, but in most of the cases recorded by the author the only possible explanation is that the bases are retained in the system and produce the rise in pressure. In gouty patients with normal blood-pressure the pressor bases are excreted in normal amounts.

Relationship of Erythemata and Joint Lesions.—A. E. Garrod states that one is not justified in assuming that the arthritis which accompanies an erythema is always rheumatic. There is little doubt that erythematous and urticarial rashes are usually of toxic origin, and the lesions of joints which accompany them are likewise due to toxic influences working at a distance rather than to bacterial invasion of the articular structures.

Salvarsan.—G. S. Taylor and R. W. Mackenna state that every fresh case of syphilis should receive a full dose of salvarsan, preferably by the intravenous route, unless there is some contraindication. If at the end of three weeks the patient does not give a negative Wassermann reaction the advisability of a second dose should be considered. The first dose will destroy an enormous number of spirochetes; the second should complete the work.

Spontaneous Fracture of Leg Bones.—E. W. H. Groves reports a case of this condition in an adult, which he attributes to sporotrichosis.

Paroxysmal Pulmonary Edema.—A. E. Carver reports two cases of this condition. The attack is described as follows: It commences with a short frequent cough of a peculiarly irritating character, the patient experiencing an urgent desire to "clear the throat." At the same time there is a sense of oppression or constriction across the upper part of the chest, which is usually accompanied by pain in the left arm or "across the shoulders." Within a few minutes the breathing becomes difficult, there is expectoration of a little frothy mucus, which may be brightly tinged with blood, and the general condition becomes one of restless anxiety. Rapidly the patient passes into a state of intense distress. No longer able to exert himself he collapses on to a couch or chair; the face is pallid, the lips blue, and the body bathed in a cold sweat. The pulse is frequent, the respirations rise to forty or more to the minute, mucus rattles in the throat, and consciousness is sometimes lost. To the onlooker a fatal termination appears to be immediately impending; but after persisting for from two to four hours the symptoms gradually abate, and presently the patient sinks into a sleep from which he awakes a few hours later, tired but otherwise little the worse.

Late Results of Gastroenterostomy.—R. Bevan describes the present condition of a patient fifteen years after gastroenterostomy had been performed for pyloric obstruction. For the past five years the operation opening has more or less ceased to act, compelling food once more to find its way through the pyloric opening as best it could. This has been accompanied with more or less pain, though the latter has not been as great as that experienced during the preoperated period.

Pneumothorax.—A. E. Sanderson reports a case of pneumothorax complicating bronchopneumonia in a child aged two years.

British Medical Journal.

Observations on Rational Empiricism and Scientific Medicine; the Boundaries Dividing Them. Sir Dyce Duckworth.
Remarks on Food and Feeding. R. Saundby.
Cancer Credulity and Quackery. E. F. Bashford.
Bonesetting. H. Marsh.
Quackery—With Special Reference to Female Complaints. Sir John Byers.
Skin Diseases and Cosmetics. G. Pernet.
The Practice of Medicine and Surgery by Unqualified Persons. J. H. Taylor.
Quackery in Rural Districts. C. E. S. Flemming.
Unqualified Practice in East Anglia. E. G. Barnes.
Bonesetting and the Treatment of Painful Joints. F. Romer and L. E. Creasy.

Rational Empiricism and Scientific Medicine.—Sir Dyce Duckworth states that a large part of the best practice of medicine is still, and probably will be for a long period, an art, although founded on many branches of science. Much of the best medical practice is still empirical. In its essence, empiricism is the product of "experience founded on observation alone" (Sir William Hamilton). Empiricism has often anticipated science in medicine. But there is no room for empiricism in pathology. There has been some tendency to neglect the older means for affording relief to many symptoms during the progress of specific treatment in combating the original malady. Rational empiricism, together with slowly progressive scientific medicine, is now being carried on by the best practitioners.

Food and Feeding.—R. Saundby discusses some of the modern fads and tendencies with respect to diet. There is at present being waged in England a campaign in favor of a so-called "standard bread," made from whole wheat or graham flour. Yet white bread has been shown by analysis to contain a larger percentage of protein than graham bread. Not infrequently inferior grades of flour are palmed off on the public as graham flour. The connection between beriberi and polished rice has suggested a similar connection between some other form of bodily ailment and the use of fine white flour. A change is desirable in the general introduction of machinery for bread making. The present condition of many bakeries, which

are overheated cellars filled with half-naked men from whose bodies sweat pours to mingle with the dough, is not pleasant to think of. The author alludes to the new fads of fasting-cures, the no-breakfast plan, the uncooked food cult, vegetarianism, and fruitarianism. Vegeterianism is receiving considerable scientific support. The restriction in the consumption of animal food is favored by authorities on dietetics in various countries, Marcel Labbé in France, Umber and Otto Cohnheim in Germany, Chalmers Watson in England, and Chittenden in America.

Cancer, Credulity and Quackery.—E. F. Bashford describes the numerous alleged cancer cures that have been exploited before the public. He states that the moral of all the familiarity with cancer and all the quackery associated with the exploitation of those sufferers who would fain find an alternative to the knife is simply this. A secret remedy for cancer is possessed by no man nor woman. If it existed, its success would speedily cause all human endeavor to concentrate upon its divulgence, and no quack could retain it for himself alone. That form of treatment which is public property—namely, removal by surgery—has nothing to fear, but, on the contrary, much to gain by comparison with its only competitor, removal by caustics. In this one word, "caustics," Bashford continues, can be summed up the direct application of all the numerous suggested substitutes for the knife, from trypsin and radium and other actinic forces to potassium bichromate, formic acid, formalin, and arsenic.

Bonesetting.—H. Marsh, moved by the support given by a prominent London journalist to a popular mechanotherapist in Park Lane, presents an elaborate article on this subject. The success of the bone setters is apparently due to their skill in manipulation, particularly about the joints. In this way they may break up old adhesions, correct displacements of muscles or tendons, or of the semilunar cartilages of the knee. Manipulation, with the strong mental impression it produces, is a very good method by which to treat cases of so-called hysterical contraction of the joints.

Quackery and Women.—Sir John Byers states that women are more imposed upon by quacks than men are for the following reasons: They are by their nature more confiding and less wary than men are. Many women are specially prone to functional nervous disorders and so become the special prey of the quack. Women in many cases have a natural desire to keep their ailments secret. They are also ready purchasers of various nostrums for improving the personal appearance. Remedies for the cure of "female irregularities" find a large sale among them.

Skin Diseases and Cosmetics.—G. Pernet discusses quackery and its remedies with reference to diseases of the skin.

Practice of Medicine by Unqualified Persons.—J. H. Taylor recommends legal reforms in the regulation of the practice of medicine with the object of suppressing the evils of unqualified practice.

Quackery in Rural Districts.—C. E. S. Flemming notes the following agents that are effective in furthering the work of the quack among the rural population; newspapers, chemists, stores, grocers, cooperative societies, the postoffice, the street vendor, the clergyman and the district visitor.

Unqualified Practice in East Anglia.—E. G. Barnes states that the place of the itinerant quack is being taken by the prescribing chemist, the medical botanist, and the consulting optician.

Bonesetting and Painful Joints.—F. Romer and L. E. Creasy describe the principles underlying the practice of bonesetting in the after-treatment of bone and joint injuries.

Münchener medizinische Wochenschrift.

May 23, 1911.

Therapeutic Use of Hypophysis Extract.—Klotz has tested several preparations of the extract as made by leading houses. The drug, however, is not in extract form, for the entire substance of the fresh gland is placed on the market in three-grain doses. Thus far no dosage has been devised. Animal experiment shows that very massive quantities can be tolerated without ill effects. The chief practical interest at present in this preparation lies in its apparent promise in gynecology and obstetrics. Since it seems, when injected intramuscularly, to act as a heart and vascular tonic and also as a uterine stimulant, it should be indicated in atonic uterine hemorrhage, not only to arrest the latter, but also to antagonize the resulting acute anemia. The extract has been used in England in operative shock, apparently because it antagonizes the lowered blood-pressure which seemingly underlies that condition. In the association of shock with concealed hemorrhage—such as occurs in ruptured tubal pregnancy—it should be of value. The extract should be of use in peritonitis, in which condition we have a toxic depression of blood-pressure. It also antagonizes the arrested peristalsis and urinary stagnation. The remedy naturally comes in competition with the more dangerous adrenalin, which has been used for all the preceding conditions. Adrenalin, however, is by no means a synergist of pituitrin, for the former acts diametrically opposite to the latter in some conditions. Its action on the heart is brusque and transitory while pituitrin acts slowly and steadily. Adrenalin also tends to slow intestinal peristalsis, and hence is not adapted to the treatment of peritonitis in the author's opinion, although much depends on the point of view.

Adrenalin in Peritonitis.—Holzbach's article follows the preceding, although it is not intended as a reply to it. The author believes that adrenalin, injected intravenously, is theoretically indicated in the treatment of peritonitis. He would combine the drug in saline solution and use it continuously. The action of adrenalin on the diseased organism must be ascertained. By poisoning the isolated heart with arsenic and then infusing the drug in very dilute solution the weakened systole becomes strengthened and in time becomes normal in force. The weakened heart and lowered blood-pressure of peritonitis, also due to a toxic substance, appear to indicate the same sort of remedy. In the dosage required by this method of treatment adrenalin has no toxic overaction or collateral action. The author does not allude to the action of adrenalin on the intestine, kidneys, or bladder in the subject with peritonitis.

Diagnostic Significance of Enlarged Cubital Glands in Children.—Grosser and Dessauer, after a study of this lesion in children, especially nurslings, conclude that it is without special significance. In the nursling it is of some value in the diagnosis of syphilis, but only 34 per cent. of luetic children showed the enlargement, in contrast with the 42 per cent. of rachitic children who exhibited the same. The older view that these swellings are in any way indicative of syphilis or tuberculosis has doubtless been largely exploded by the introduction of the new biological reactions. The combined material of the authors reads as follows: Of 1,066 nurslings over 1,000 had neither rickets, lues, nor tuberculosis, and 4.6 per cent. had enlarged glands. Of fifteen with hereditary lues ten exhibited the latter; of fourteen tuberculous nurslings but one was thus affected; of twenty-nine rachitic children twelve showed the enlargement; of 831 older children 668 had neither lues, tuberculosis, nor rickets, and 6.3 per cent. had enlarged glands; of fourteen with hereditary lues four presented the latter; of 106 tuberculous children twenty-four were affected thus, and of forty-three rachitic children, fourteen.

Book Reviews.

Some Neglected Factors in Evolution. An Essay in Constructive Biology. By Henry M. Bernhard, M.A., Cantab., F. Z. S. Edited by Maltida Bernard. With 47 illustrations. New York and London: G. P. Putnam's Sons, The Knickerbocker Press, 1911.

Mr. Bernard was at one time a student under Professor Haeckel. The neglected factors of evolution with which Mr. Bernard concerned himself are the fundamental network universally present in protoplasmic tissues. This factor is dealt with in Part I of this work. "Periodicity," or "Rhythm," another neglected factor, is treated in Part II, together with other factors, the evolutionary periods inaugurated by the series of units of structure. Colony formation is the essential factor in producing new types of organic life and the psychic bonds which, in the human colonies built up by man, take the place of the physical bonds connecting the units of other colonies.

Mr. Bernard's opinion was that the cell doctrine was too crude to account for all the phenomena, that what are called "cells" are merely form features of some deeper underlying texture.

Th protomitomic theory is sketched by Mr. Bernard and is not worked out; but, judging from the material in the book before us, leads to the hope that this incursion into new regions of biology may inspire living biologists to carry on the researches to a satisfactory conclusion. The book is well edited and capitally illustrated.

Science from an Easy Chair. By Sir Ray Lankester, K.C.B., F.R.S. With eighty-four illustrations. Price $1.75. New York: The Macmillan Company, 1911.

This is a fascinating book, and, although written by one of the greatest living naturalists, is worded in easy, flowing language, intelligible to the lay reader. In fact, the papers contained in the volume were first published in the London *Daily Telegraph,* and of course, as the title of the book denotes, intended for popular consumption. The scientific man is in his dressing gown and slippers and discards for the nonce the technical phraseology of science. The chapters concerning Darwin are especially illuminative, in view of the belief that appears to be becoming current that Darwin's theory of the origin of species has been exploded or discredited. The chapter, also, on the meeting of Metchnikoff and Tolstoi, describing the discussion between these two great Russians of divergent views, holds one from beginning to end. Most of the illustrations, from drawings by the author himself, are exceptionally good and the entire book may be earnestly commended to the consideration of medical men and laymen alike.

Tuberculosis as a Disease of the Masses and How to Combat It. Prize Essay by S. Adolphus Knopf, M.D., New York, Professor of Phthisio-therapy at the New York Post Graduate School and Hospital; Director in the National Association for the Study and Prevention of Tuberculosis; Associate Director of the Clinic for Pulmonary Disease of the Health Department; Visiting Physician to the Riverside Hospital Sanatorium for Consumptives of the City of New York, etc. Seventh American Edition, Enlarged and Revised, with 64 Illustrations. In cloth, 50 cents; in paper, 25 cents. New York: "The Survey," 1911.

Little need be said in praise of this very excellent book on tuberculosis. That it has already gone through seven editions is a sufficient proof that its worth has been well recognized. The present edition is somewhat larger and has been revised and gives an authentic, up-to-date presentation to the lay reader of the situation as regards tuberculosis by an acknowledged authority.

Hygiene and Public Health. By Louis C. Parkes, M.D., D.P.H. Univ. of Lond., Consulting Sanitary Adviser to H. M. Office of Works; Curtian Sanitary Member of the Advisory Board for Army Medical Services; Medical Officer of Health of the Metropolitan Borough of Chelsea; Examiner in Public Health to the Royal College of Physicians and Surgeons, London; Fellow of the Royal Sanitary Institute, and Henry R. Kenwood, M.B., F.R.S. Edin., D.P.H. Lond.; Chadwick Professor of Hygiene in the University of London; Medical Officer of Health and Public Analyst to the Metropolitan Borough of Stoke Newington; Examiner in Public Health to the Royal College of Physicians and Surgeons, London; Fellow of the Royal Sanitary Institute. Fourth Edition, with Illustrations. Price, $3.50. Philadelphia: P. Blakiston's Son & Co.

Among English-speaking people Parkes and Kenwood have a reputation second to none as authorities on sanitary matters, and their book on Hygiene and Public Health well upholds their fame. It may perhaps be said that it is the best work on these subjects published. Before Mr. Kenwood collaborated with Dr. Parkes the latter's "Hygiene and Public Health" had run through five editions, and under the joint authorship it has gone through three editions, sufficient testimony to its worth. All matters dealing with public health and hygiene are discussed fully but with commendable brevity. The chapter on air and ventilation is of exceptional merit, as, despite Sir Almroth Wright's recent statement that the health-giving properties of fresh air are greatly overrated, there is little doubt that sanitarians will continue to evolve means whereby the greatest amount of fresh air possible is introduced into rooms and public buildings. Indeed, as Parkes and Kenwood point out, researches have shown that, of all the industrial classes, those which are the healthiest and have the lowest death rates are the gardeners, farmers, agricultural laborers, and fishermen, those, namely, whose occupations are carried on in the open air. As for warming rooms and buildings by low and high pressure steam systems, the authors express themselves as in favor of the vacuum system for the reason that the temperature of the steam does not rise above 212° F. It is pointed out that soft water is far preferable to hard water for use in boilers and hot water pipes. In the chapter treating of exercise and clothing the evil effects of tight clothing and tight lacing are referred to. For women the substitution of warm "bloomers" for the petticoat is recommended. The authors are strongly in favor of public rather than of private abattoirs, as in their opinion these constitute the only possible means of proper and systematic inspection at the time of slaughtering animals, such inspection being necessary to prevent the sale for human food of diseased meat. One of the most valuable chapters of the book is that relating to disinfection. Arguments have been brought forward recently both in this country and in Great Britain that disinfection is of little use. This may be true when the process is not carried out properly or when in the case of the use of disinfectants the germicidal properties of these is not known. To disinfect in order to destroy the germs of specific disease it is necessary first to know whether the disinfectant employed is capable of so doing. In Great Britain within the past few years endeavors have been made to standardize disinfectants; that is, to set a standard method of comparison that shall be both scientific and easily practicable, in which the various agents are tested side by side under precisely similar conditions. Rideal and Walker have devised such a method, taking carbolic acid as the standard disinfectant and *Bacillus typhosus* as the standard germ in such tests. Although the method is not perfect, Parkes and Kenwood describe it as a useful one upon which it may be found possible to base a practical test. The book is well bound and printed, while the illustrations serve the purpose for which they are intended effectively.

A Text-Book of Surgical Anatomy. By William Francis Campbell, M.D., Brooklyn-New York; Professor of Anatomy, Long Island College Hospital; Attending Surgeon to the Methodist Episcopal, Swedish, and Bushwick Hospitals; Consulting Surgeon to the Jamaica Hospital. Second Edition, Revised, with 319 original illustrations. $5.00. Philadelphia and London: W. B. Saunders Company, 1911.

This work deals with descriptive anatomy from the surgical standpoint. The author has not been too ambitious in his range, but has confined his descriptions to anatomical facts and has laid emphasis on those structures and regions which are of chief surgical interest. A special feature of the book is the large number of really beautiful illustrations, which it is needless to say are a great aid in explaining the text. The work in all its details is eminently satisfactory and can be recommended as a useful work for reference for surgeons and general practitioners.

Manual of Clinical Pathology. By Richard Weiss, M.A., Ph.D., F.C.S., in Collaboration with George Herschell, M.D. (Lond.), and Andrew Charles, F.R.C.S. (Dublin). Price 80 cents. London: J. & A Churchill; Philadelphia: P. Blakiston's Son & Co., 1910.

This is a small paper volume of 72 pages, including most of the important clinical tests which can be carried out in daily practice without laboratory facilities, in addition to the usual tests necessary in clinical diagnosis. The section dealing with the analysis of urine is particularly thorough and at the same time concise, advantages which commend it for quick and easy reference. The description of the methods of examination of stomach contents, feces, and blood, and of the serum diagnosis of syphilis, tuberculosis, and typhoid fever is also in keeping with the eminently practical aim of this book.

MEDICAL LIBRARIES.

III. 1911.

THE name of the library is followed by its post office address, the librarian's name and the number of bound volumes. With the exceptions indicated, the list is made up from recent returns. Copies may be obtained by enclosing a postage stamp to the librarian of the New York Academy of Medicine. The chief object of presenting the list is to facilitate donations and exchanges. Historical and economic details, degrees, and official titles are therefore omitted.

ALBANY—New York State Medical Library, Albany, N. Y., U. S. A. Miss Ada Bunnell. 21,790.

AMSTERDAM—Library of the Netherlands Medical Society. Singel 21, University Library, Amsterdam, Netherlands. Dr. C. E. Daniëls. 25,000.

ANTWERP—Library of the Antwerp Medical Society, Royal Atheneum, 40 rue van Straelen, Antwerp, Belgium. Dr. Edward d'Haenens. 3,150.

ATLANTA—Library of the Atlanta Medical Library Association. Atlanta, Ga., U. S. A. Dr. H. F. Harris. 2,000.

BALTIMORE—College of Physicians and Surgeons, Library of the. Calvert and Saratoga streets, Baltimore, Md., U. S. A. Miss Ethel I. Disney. 1,275.

Johns Hopkins Hospital Library, North Broadway, Baltimore, Md., U. S. A. Miss Minnie W. Blogg. 10,400.

Johns Hopkins Medical School Library, Monument and Washington Streets, Baltimore, Md., U. S. A. Dr. M. L. Raney. 10,973.

YORK, U. S. A.—Library of the York County Medical Society, Court House, East Market street, York, Pa., U. S. A. Dr. Israel H. Betz. 3,500.

Society Reports.

ASSOCIATION OF AMERICAN PHYSICIANS.

Twenty-sixth Annual Meeting held in Atlantic City, N. J., May 9 and 10, 1911.

(Special report to the MEDICAL RECORD.)

THE PRESIDENT, DR. FORCHHEIMER OF CINCINNATI, IN THE CHAIR.

(*Concluded from page 1076.*)

The Work of the Heart in Aortic Insufficiency.—Dr. W. G. MACCALLUM of New York said that by means of an apparatus designed to measure the outflow of the blood from the left ventricle, variations produced in the amount and character of the outflow by injury to the aortic valves could be studied. The character of the arterial pulse could also be studied by this method and its relation to the blood pressure and peripheral and central escape estimated.

Percussion Signs of Persistent and Enlarged Thymus.—Dr. THOMAS R. BOGGS of Baltimore said that persistent and enlarged thymus glands were more frequent than ordinarily recognized. They were common in children and adolescents, with general glandular enlargement or tonsillar hypertrophy, or both. They were recognized by median pressure in the first and second intercostal spaces to the left of the manubrium, sometimes on both sides; rarely, however, on the right side alone. They were differentiated from enlarged mediastical glands by (1) the superior and more superficial position; (2) the common position to the left of the manubrium; (3) by a special maneuver which depended upon the movable character of the thymus and its attachments to the lower pole or poles of the thyroid; (4) the maneuver; the patient should be in the sitting posture with chin depressed. The lower border of the thymus dullness should then be outlined. Then while the plexiimeter fingers were kept exactly in place the head should be sharply retracted to the fullest extent. The thymus dullness would then rise upward toward the neck, leaving a clear percussion resonance. Mediastinal adenitis, aneurysms, and neoplasms did not give this shifting dullness.

The Effect of Some General Hydrotherapeutic Procedures Upon the Blood Flow in the Arm.—Drs. A. W. HEWLETT, J. G. VAN ZWALUWENBURG, and MARK MARSHALL of Ann Arbor, Mich., presented this communication. They reported the results of some studies of the effect of some of the ordinary hydrotherapeutic procedures upon the blood flow in the arm. Warm procedures increased the flow from two to ten times the original rate. Cold procedures usually lessened the flow, but the exercise and friction given in an ordinary cold shower might cause a moderate acceleration of the flow. The chief cause of the acceleration of the flow in the arm not directly exposed to the heat was a vasomotor reflex initiated by the stimulation of cutaneous sense organs, but the rise of body temperature accompanying hot procedures tended to prevent an excessive contraction of the peripheral vessels with chilling when the individual was exposed to cold. If the body temperature was subnormal an immediate reaction might follow cold procedures which were accompanied by friction and exercise, but the individual was liable to become chilly later. The chilliness, which indicated a failure to react, was accompanied by a slow rate of blood flow in the arm. Reactions were usually, but not necessarily, accompanied by normal or moderately increased rates of flow.

Dr. Henry Sewall of Denver believed that what they had been studying was the cutaneous circulation and not the circulation *in toto*. Therefore when they talked of an increased blood flow in the arm it was not clear whether that increased blood flow was washing the muscles or simply an increased blood flow in the skin itself.

Dr. Solomon Solis Cohen of Philadelphia said he had had considerable clinical experience with hydrotherapeutic measures and he was inclined to think that the external circulation was not an index to the condition of the internal circulation; they might vary concordantly and discordantly. There were two factors which were very important to consider, pressure and time. Mere pressure alone would not produce definite results. The application of cold compresses would at times raise the body temperature; this was shown more markedly in patients with fever than in a normal person. With regard to the effect of heat or cold upon the opposite arm he referred to a remarkable phenomenon which possibly showed the vasomotor reactions to be at fault. If one took a man who was extremely cyanotic and immersed one hand in ice water, that hand would become reddened although cold. This showed that the blood had been forced from the veins and had accumulated in the capillaries. In the untreated hand the cyanosis was increased. In other words the very opposite effect took place in the untreated hand.

Dr. A. W. Hewlett believed that the circulation was more in the skin than in the muscles; however the color of the skin gave practically no information as to the rate of the circulation in the arm. No reliance could be placed upon the color of the skin.

A Case of Pseudochylous Ascites.—Dr. Frederick P. Henry of Philadelphia reported this case. The patient was a man sixty years old, but he looked older. He was admitted to the hospital with ascites. In four months he was tapped eight times; the smallest amount removed was six quarts, the largest eight quarts. After each tapping a mass could be felt in the abdomen above and to the right of the umbilicus. The Wassermann reaction was positive although the patient denied ever having had syphilis. The patient died. The autopsy was performed by Dr. Joseph McFarland, an experienced pathologist. There was found a tumor at the pyloric orifice of the stomach cancerous in nature. The liver appeared to be perfectly normal although they expected to find it sclerotic. This showed how very difficult it was to make, in some cases, a diagnosis of cirrhosis of the liver. Dr. Henry called attention to the distinction between chylous and pseudochylous effusions. The milky appearance of the latter was due to a combination of serum-globulin with lecithin or other lipoid material. The remarkable resistance to putrefaction displayed by pseudochylous effusions was due to lecithin as proved by the fact that on the abstraction of the lecithin they rapidly decomposed. The view of Senator that the presence of sugar was indicative of the chylous nature of an effusion was no longer tenable. In the case reported the ascites was not explained by autopsy, there being no demonstrable obstruction of the portal circulation or alteration of the peritoneum, the chief lesion being a cancer of the pylorus. The liver was in a healthy condition.

The Vascular Lesions of Experimental Nephritis.—Dr. Henry A. Christian of Cambridge, Mass., reported some experimental work done on a series of animals with uranium nitrate, potassium chromate, and with arsenic. The lesions produced in the kidneys were confined entirely to the glomeruli.

Further Studies in Sensitization in Tuberculosis.—Dr. V. C. Vaughan, Jr., of Detroit, Mich., read this paper and called attention to the value of the ophthalmo-reaction in the diagnosis and prognosis of tuberculous disease, especially in those patients who were free from the active manifestations of the disease. The tuberculin reaction was an index of the value of specific treatment and experiments in the sensitization of children, of (1) clinically non-tuberculous parents, (2) clinically tuberculous parents, to tuberculin.

Dr. Lawrason Brown of Saranac Lake, N. Y., said that one could not sensitize an animal not tuberculous either through the skin, the eye, or subcutaneously unless they injected large doses of the dead bacilli or living bacilli. If sensitization took place there must be some tuberculosis present. In a healthy animal the only reaction would be an anaphylactic one. But they would get no reaction from an ordinary tuberculin test.

The Chemical and Energy Metabolism in Sleeping Infants.—Dr. John Howland of New York reported some interesting experiments made upon four different children with a modified Atwater-Rosa-Benedict calorimeter; by means of this apparatus the heat produced by sleeping infants had been for the first time directly measured, The respiratory exchange was also determined. The results obtained by direct and indirect calorimetry were compared, and also the difference in the heat produced during sleeping and waking. The effects of fasting and of the ingestion of different foods had also been determined. The apparatus he demonstrated was exceedingly accurate. After the infants had become accustomed to the use of the rectal thermometer, they were fed every four hours, or six times during the twenty-four. One child weighing 4.32 kg. with a surface area of 3,263 cm. during the first hour when sleeping produced 1,102 calories; during the second hour when awake produced 1,358, and during the third hour when crying 1,506 calories.

Tricuspid Stenosis with a Report of Five Cases.—Dr. Thomas B. Futcher of Baltimore made this report. The paper dealt especially with the report of one case of tricupsid, aortic, and mitral stenosis, with the autopsy, in which the diagnosis was made during life. In the autopsy records of the Johns Hopkins Hospital there had been only four other cases of tricuspid stenosis out of a total of 3,500 autopsies. There had been only eight cases in the medical wards, out of a total of 26,000 admissions, in which the diagnosis of tricuspid stenosis was made either from the physical examination or autopsy findings. A positive diagnosis by autopsy was made in only five cases. The number of cases of tricuspid stenosis in the literature number 194 and in only 12 was the diagnosis made clinically. Presystolic murmurs in the veins of the neck and of the liver should be looked for. The character of the pulse was rather suggestive; it was extremely small. The heart was increased in size, and more to the right. One should look for extreme cyanosis in a woman, one who probably had had rheumatism; also for signs of a mitral stenosis and considerable enlargement of the cardia to the right; then the condition of tricuspid stenosis should be suspected.

The Intestinal Infantilism of Herter.—Dr. Rowland G. Freeman reviewed the literature on this subject and reported cases. In spite of the work that Herter did, his work in this would be the one probably that he would be recognized by. This condition was described by Herter three years ago. There were certain types of dwarfs, sexual and asexual. In this latter type there were the following subdivisions: The infant type—an angioplasia (Loraine); Adolescent type (Brissand); Lymphatic type, Mongolian; Thyroid or cretinism; Achondroplastic; Intestinal (Herter); Hepatic (Cautley); Pancreatic (Bramwell). The cause of intestinal infantilism of Herter was probably due to colitis. They suffered from a severe lassitude after giving a history of having had colitis. There was a failure to gain in weight. They had characteristic gray movements. They had peculiar intestinal flora and certain changes in the urine.

Dr. F. C. Wood of New York said that the examination

of the urines and stools from some of these children showed very interesting conditions, corresponding in general with those described by Herter in his publications on infantilism. The urines were, as a rule, free from albumin. They showed very large amounts of putrefactive products, notably indoxyl, indolacetic acid, and the aromatic oxyacids. Phenol, too, was often abundant, but each individual case varied in the dominant product present, some having large quantities of indolacetic acid and some showing very large quantities of indoxyl, the maxima corresponding with the children's clincal relapses. The amount of these substances was sometimes quite extraordinary, as large as was ever seen in adults. The stools contained small quantities of indol, and on one occasion skatol was found. The bacteriological examination of the stools showed a dominant Gram-positive flora, in some cases almost no Gram-negative organisms being present. There were, however, from time to time, considerable variations; occasionally after a relapse the fields would be largely Gram-negative. Almost always, however, large organisms were present, which either belonged to the subtilis group or were *B. aërogenes capsulatus*. Gram-positive bacteria of the bifidis and infantilis type were also regularly present, as were organisms known as enterococci. The large, acid-resisting, oval bodies described by Herter were also frequently found.

Brill's Disease, with Illustrative Cases.—Dr. Morris J. Lewis of Philadelphia read this paper. He said that this was an acute infectious disease, with an incubation period of about one week or longer. The fever reached its height in about three days, subsided in about two weeks, with only slight remissions, and ended by crisis or lysis, usually the former. The fever was accompanied by an intense headache, and injected eyes, lasting until the defervescence. A profuse macular eruption appeared at the height of the fever, most copious upon the chest, abdomen and back, but also extended to the extremities, and even appeared on the palms of the hands and soles of the feet. The eruption resembled somewhat that of typhus fever; it did not disappear on pressure; it was erythematous, of a dull, brownish red color, and but rarely hemorrhagic. There were no abdominal symptoms; the leucocyte count was not low as was usual in typhoid, but not as high as in typhus fever. All examinations of the blood for evidence of typhoid or paratyphoid fever were absolutely negative. The eruption was too uniform in appearance to be explained by possible accompanying intestinal disturbances; it did not in the least resemble the eruptions seen after the administration of certain drugs, nor that due to the presence of parasites. It was much too free for, and did not in the least resemble that of, typhoid fever. Although it seemed highly probable that this disease was a clinical entity, it so closely resembled, in many aspects, typhus fever, that the possibility of it being an atypical form of the same must be borne in mind. Increasing clinical experience, however, pointed in the other direction. This report was based on the study of fourteen cases.

Dr. E. Libman of New York said that since Dr. Brill had published his first paper he had drawn his attention to the records of two further autopsies so that there were now records of three fatal cases. In all the lesions were not unlike those found in typhus fever. In the last case the bone marrow of the femur and tibia was examined. It was found to be red in color and the microscopical examination showed evidences of regeneration. The same lesion was found in typhus fever. Of course, this did not at all prove that the two conditions were identical.

Acute Leukemic Tuberculosis with Purpura Hæmorrhagica.—Drs. James Ewing and W. B. Coley of New York reported this case. In February, 1909, a woman was admitted with a sore throat. Two weeks prior her son recovered from apparently a similar condition, and the mother apparently recovered as well. There were swellings of the lymph nodes in the neck and a rise in temperature. A consultation was called for. In December she had a very profuse purpura hæmorrhagica, an elevated temperature, and was a very sick woman. The skin was dusky, and the lymphatic nodes in the neck had enlarged. Finally her temperature rose to 106° F. and she died seven weeks after the beginning of her symptoms. At autopsy among the more interesting conditions noted were the enlargement of the abdominal lymph nodes, an enlarged and distended colon, pin-head miliary areas, and it was believed that this might be a case of lymphomata. The microscopical examination revealed undetected lesions. There were areas of necrosis and fresh hemorrhages; these hemorrhages were surrounded by giant cells containing many necrotic lymphocytes. The points of special interest in this case were as follows: The acute infection by the human type of tubercle bacilli and a fatal termination in seven weeks. It was suggested that the disease had something to do with the leukemia; leukemia might arise in some cases as the result of tuberculosis. The hemorrhagic lesions were very marked.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON OBSTETRICS AND GYNECOLOGY.

Stated Meeting, Held March 23, 1911.

Dr. Henry Dawson Furniss in the Chair.

Stereopticon Demonstration of Colored Microphotographic Slides.—Dr. Frances Cohen presented these slides which were made by her in the Schauta Frauen Klinik in Vienna under the direction of the Director of the laboratory who had spent over a year in perfecting his process and upon which he was still working. His method would be published in the journal connected with the clinic in the near future. This series was believed to be the first shown in this country in which the microscopic images of a specimen had been transferred with an absolute reproduction of the staining to a photographic plate. The use of the plate as a stereopticon slide resulted in the exact retention of the original coloring in the now further magnified image on the sheet, and thus by making it possible to demonstrate specimens to large classes at once became a more valuable adjunct to the teaching of pathology. A series of such slides could readily be made for the various clinics illustrating their special histological and pathological subjects and might be used to make clear to classes what formerly had to be shown entirely by the use of the microscope or by hand-colored plates.

Dr. Leopold Jaches threw some pictures on the screen; these he took over three years ago. He did so to show that he was unable to obtain such clear pictures as were presented by Dr. Cohen.

Vesical Calculus Following Pubiotomy.—Dr. Howard Canning Taylor presented this specimen. It was 4 cm. in length, 2 cm. in width, and weighed 12 gms. The woman entered one of the maternity hospitals two years ago when she was forty years old for her first confinement. On account of the disproportion between the size of the child and the maternal parts a pubiotomy was done. In the delivery of the child, not by the pubiotomy itself, an opening was torn into the bladder. An attempt was made to close it at the time of delivery but without success. Subsequently four or five trials were necessary before the vesico-vaginal fistula was closed. This was probably because of the proximity of the fistula to one of the ureteral orifices. She was well until about six months before entering Roosevelt Hospital with symptoms of cystitis. The urine contained considerable pus, mucus and a large number of colon bacilli. A cystoscopic examination revealed the calculus movable at the base of the bladder. This was

removed. There were three possible origins of the calculus. A small piece of bone from the pubiotomy might have found its way into the bladder and acted as a nucleus. A piece of ligature or suture from one of the operations for the fistula might have been the nucleus. Some of the urinary salts that were deposited about the edges of the fistula might have been the starting point of the calculus. Dr. Taylor thought this last possible source of origin to be the most probable one.

A Case of Intraligamentous Pregnancy at Term.—Dr. Ross MacPherson reported this case because of its extreme rarity. In fact this was one out of three cases taken from a series of 75,000 cases at the Lying-in-Hospital. The patient was twenty-one years old. She had had no miscarriages. On February 18, 1911, she apparently was at term. When seen she was believed to have a fibroid of the uterus. On palpation the parts were soft; there were no fetal heart sounds detected. There was a mass behind the uterus that did not contract. The fetus, however, was palpable and lying in the correct position. It was believed that this was a case of saculation of the uterus. Under anesthesia the fingers readily dilated the cervix and a portion of the uterine cavity. A diagnosis was then made of intraligamentous pregnancy. The abdomen was then opened and the diagnosis corroborated. A child weighing 3800 grams was extracted. They thought they could remove the placenta without difficulty; in attempting to do so there occurred a tremendous hemorrhage which required packing to control. The patient, except for a phlebitis in the leg, made an uneventful recovery.

Dr. John O. Polak had seen one similar case and the interesting point that was brought out was the means of controlling the hemorrhage. Another case he saw was with the late Dr. Skene some eighteen years ago; after being in attendance on the woman all night there was no dilatation of the cervix; Dr. Skene was then called in and made a diagnosis of an intraligamentous pregnancy. The operation performed was very simple but there was a very prolonged convalescence and the placenta, which was left in situ, gave trouble; the leaving in of the placenta caused the prolonged convalescence. Dr. Polak had seen two other cases that had been operated on by other men; in both of these cases the placenta was placed in such a position that it was impossible to ligate the vessels or control the blood supply. In Dr. Polak's case there was no one vessel but several vessels and the hemorrhage was fearful; the patient was exsanguinated; if she had not had a very good resisting power she would without doubt have died.

Dr. William S. Stone said he had had no cases of intraligamentous pregnancy but that he had assisted at two operations for this condition and he had seen two others. Dr. Polak brought out a very important point and one especially related to the diagnosis of intraligamentous pregnancy before operation.

Dr. Simon Marx said he had seen one or two such cases and he had used heroic treatment and was very glad that he did so. Otherwise he might have had a rupture of a tubal pregnancy with ill effects following.

Dr. Robert L. Dickinson said he had seen two such cases and both were treated by the slow method. In one case where packing was employed there was a long and distressing period; the placenta came away piecemeal.

Dr. A. Ernest Gallant reported two cases of intraligamentous pregnancy at term, one seen with Dr. Marx and one with Dr. Coe. One case was packed and the suppuration was profuse. In one case there was a dead fetus at the eleventh month which was removed as well as the placenta. The edges of the opening in the vagina were turned in and sutured and this gave no trouble whatever; he practically closed over with peritoneum the opening in the vagina.

Dr. John O. Polak, discussing Dr. Gallant's case of a dead fetus at the eleventh month, said that he gained from the literature that in these over-time dead fetuses the placenta could be removed without these profuse hemorrhages. In the case he reported it was not possible to remove the placenta without much hemorrhage.

A Case of Ureteral Calculus.—Dr. Madge C. L. McGuinness reported the history of a case that extended over a period of twelve years. The woman had painful attacks on the right side. Every six months she would have paroxysms of vomiting which lasted for twenty-four hours. For four years she paid but little attention to them as the attacks came on so seldom. Finally the attacks became so bad she consulted several doctors and they made diagnoses of lumbago, rheumatism and other things. For two years no diagnosis was made. Her paroxysms of retching and vomiting increased in frequency and severity so that during the past few weeks they had come on every six days and lasted forty-eight hours each time. She thought that possibly there was a stone in the pelvis of the kidney or ureter. Dr. Furniss performed a cystoscopy and her diagnosis was substantiated.

Dr. Henry Dawson Furniss presented the radiograph which was taken by Dr. Jaches; a shadow was shown below the stilet. When he first saw the patient he thought the stone was situated in the lower end of the ureter causing obstruction in the renal pelvis. He recently had had two cases with exactly the same symptoms except in one case there was pus in the urine. In one case there was no urine from one side because the kidney was destroyed; but the other case gave a history exactly like the one obtained in Dr. McGuinness's case. In one patient at the lower pole of the kidney were noted aberrant blood vessels apparently arising from the aorta. The kidney was distended and the ureter was very small. The kidney was cystic as well. In this patient the attacks occurred every six days. They would come on after exertion. These paroxysms seemed to come on when the ureter tightened upon the stone and occurred with nearly equal intervals.

Incontinence of Urine in Women.—Dr. Howard Canning Taylor read this paper. (See page 1089.)

Dr. Robert L. Dickinson said that the nerve supply to the base of the bladder was a most interesting matter. A badly eroded cervix required prompt attention. These patients should be looked over systematically. One should look for urethritis. Dr. Reynolds told him that he could cure some of these chronic cases by correcting their posture. The slumping woman, the one with the gorilla attitude, he could cure by making her assume the military attitude. It was not very uncommon to find varicosities at the base of the bladder. Many of these patients could be relieved by the employment of pessaries. Electrical treatment was of benefit but much resulted from the massage. Good resulted not so much in the employment of washings as from the massage of the bladder. He had tried the use of paraffin but there was danger of its getting into the circulation. In four instances he advanced the urethra; in two cases there was persistent incontinence and these patients were completely cured for three months when the original cause of the incontinence returned and they again suffered from this trouble. Raising the bladder was an important thing; it readjusted the circulation and did away with the residual urine.

Dr. William S. Stone said that it seemed to him that the situation was worse than they had been led to believe from the discussion. There were a large number of cases in which they were unable to give any definite reason why every time the patient laughed or sneezed her urine came away. This condition of incontinence of urine in women existed to a greater extent than they appreciated. Dr. Stone said he had sat with fear and trembling when listening to the history of a patient, fearful that she might com-

plain of this symptom. After all, the discussion had brought out the fact that there remained a large number of cases in which they were unable to determine the cause even after a very careful examination. Frequently they ran across cases of women who gave no previous history of any chronic inflammation and who had not given birth to children and mostly in women who were approaching the age of forty years. There seemed to be some relation in the decrease in muscular power and the amount of muscular tissue; in these cases there was an increase in the fibrous connective tissue. Analagous to these cases of incontinence of urine in women were the bleedings that occurred from the uterus when they were unable to ascribe any definite cause for the same even after the most painstaking and careful examination. The loss of the normal relationship between the fibers of the muscular tissue, plus the neurotic element, resulted in a poor general muscular condition. Fluid extract of hydrastis had been used in these cases with some benefit.

Dr. George H. Balleray called attention to the importance of being sure of the cause of incontinence of urine in women. One case he recalled was treated by a distinguished medical man and without success. He found that she was suffering from a vesicovaginal fistula through which could be passed a 16 Fr. sound. This woman had been treated by medication. Another case he recalled was that of a woman who had consulted several physicians. She had a stone in her bladder and incontinence of urine. Whenever she sneezed, coughed or laughed she passed her urine. The last physician she consulted invented an apparatus for washing out her bladder. Not one of the men she consulted made a complete examination of her bladder. Finally a true diagnosis was made and three large calculi were removed, one of them being three inches in diameter.

Dr. Simon Marx said that a very important topic for discussion was the cause of retention of urine and he reported the case of an hysterical girl, fourteen years of age. No one seemed to know just what the cause was. She was sent to the hospital for observation. At last she was anesthetized and four quarts of urine were withdrawn. This was the result of spasm of the urethra. This young girl was cured by dilating the urethra and introducing a permanent catheter which was left in for six days.

Dr. Furniss reported three cases of vesicovaginal fistula, two following an hysterectomy, the other a rectal carcinoma. The leakage of urine was not always constant. The urine would accumulate in the bladder and then, under some sudden strain, would slip away. In cases of tabes dorsalis there were many urinary disturbances.

Acute Streptococcus and Colon Bacillus Hematogenous Infection of the Kidney.—Dr. Henry Dawson Furniss reported this case. The patient was thirty-seven years old, the mother of one child seventeen years of age. On January 10, while in a theater, she had a severe chill which was followed by some temperature and pain in the left kidney region. It was first diagnosed as a case of typhoid, but later as an infection of the kidney. She was ill for about four weeks. Radiographs were taken and a shadow in the pelvic portion of the right ureter was found. After this attack she had more or less bladder disturbance with some pus in the urine. On January 10, 1911, she had an attack of grippe. When seen on January 28, she was suffering with pain in the pelvic region due to chronic tubal trouble. On February 1, ureteral catheters were passed without meeting any obstruction. At this time there was a profuse flow of light colored urine from each kidney containing no pus. On February 1, radiographs were made with the catheter in the right ureter, and it was found that the shadow before the obstruction was out of the course of the ureter. That night the patient had a chill, the temperature went to 101° F. and there was marked pain in the right renal region. From then on she had several chills with temperature ranging from the normal to 105° for four days. Then the temperature ran from 102° to 104°, but there were no more chills. Pus was found in the urine. There was a moderate leucocytosis, but the differential count was not high. The cultures of the urine showed organisms resembling the colon bacilli. Autogenous vaccines were used but without effect. On February 14, the right renal pelvis was irrigated with a solution of nitrate of silver, but this had not the least effect upon the course of the trouble. On February 19, the temperature rose to 104° and the blood count showed 20,000 whites and 80 per cent. polymorphonuclears. At no time did the pulse go over 106 and it was always of good quality. From the start of the disease the patient was much of the time irrational, and occasionally delirious. On February 21, under gas and oxygen anesthesia, after giving a preliminary saline infusion of normal saline, a nephrotomy was done. The kidney was much enlarged and congested, and had a very adherent capsule. The patient's condition did not improve and so, on February 23, a nephrectomy was performed, after first catheterizing the left ureter. The urine from the left side showed a small amount of pus. After this the patient made a good recovery, though the first few days were rather stormy. Upon examination the kidney was found much enlarged, the capsule thickened and very adherent. After removing the capsule numerous hemorrhagic spots were seen. In only one spot was pus seen. The cultures made from the kidney showed growths of the streptococcus and colon bacillus.

Criminal Abortion from the Practitioner's Viewpoint.—Dr. Walter B. Jennings read this paper. (See page 1092.)

Dr. John O. Polak said that in New York City it was very difficult for the doctor to escape the coroner's office and the District-Attorney's office especially in those cases of abortion that happened outside of public institutions. There were two points in particular that Dr. Polak wished to bring out in regard to criminal abortion. The first physician who was called to such a case had one duty, and that duty was to tell the patient that he considered such cases septic *per se;* they were all septic abortions. The law had little to do with them and one could protect himself if he would at once call in counsel; if counsel was called in then one would have little or no difficulty. In the moribund cases the coroner's office should be notified. The second point Dr. Polak wished to bring out was that they, as physicians, could not be used as witnesses against these patients. With regard to the catheters used, a number of patients were brought to them in their hospital work on whom the hard rubber catheter had been used. Most men, however, preferred the soft rubber catheters. Some used one catheter two or three times. He reported an interesting case of a patient who had metrorrhagia. After he had examined her several times he noticed a string hanging from the uterus; he brought out of that uterus a catheter which had coiled up inside that organ. The two special points that Dr. Polak wished to emphasize were, first, the duty of the physician to such patients and, secondly, that all these cases should be considered septic and treated as cases of septic abortion.

Dr. Simon Marx condemned the coroner's system that frequently fostered political hirelings. He told of an unfortunate experience in which he was called in consultation at midnight. When it was seen that there was to be a fatal outcome, two doctors ran away. Dr. Marx was arrested, taken to the police station, and kept there till he could get bail which was in the morning. However, Dr. Marx said he did not care at all to what case he was called, he would never send a case to the coro-

ner's office; if he did he would get in trouble; if he did not he would get in trouble anyway. Treat the woman: treat her as she should be treated, treat her along ordinary lines. If she died, report the death to the coroner.

Dr. Ross MacPherson said that the coroner's office paid no attention to these cases; as many as 300 or 400 cases a year were reported to that office. As one coroner said to him "What's the use of our seeing such cases; they all get off."

Dr. John O. Polak said he had been called as a witness eight times; in all these cases the women had died of septic peritonitis and the men were arrested. Not one was convicted. In one case the abdomen was drained of several gallons of pus. The party who did the operation was arrested and brought to the coroner's court. The questions of the coroner interested Dr. Polak. Such questions as these were asked: "Can you state positively that death was due to the abortion? Could it not have been due to a perforated appendix?" etc. Coroners, as a rule, did not bother with these cases.

Dr. George W. Kosmak said that the subject of Dr. Jennings' paper might always be regarded as appropriate and timely. Many of those present had probably gone through experiences of this kind and could therefore sympathize with what the writer had stated. Dr. Kosmak was glad to learn that the authorities in Brooklyn were more lenient in these abortion cases than those of New York. He had found that whenever a case of this kind occurred in the practice of a reputable practitioner, the coroner's office and the District-Attorney got busy at very short notice, while if such a case was brought to a public hospital after having been participated in by a midwife, very little was done by these otherwise over-zealous officials. Dr. Kosmak said that he was unfortunate enough two years ago to have been indirectly concerned in a case of septic abortion at a prominent private sanatorium. The patient was curetted in order to stop the bleeding and clear out the remnants of an incomplete abortion. She was evidently septic before coming under the care of the speaker's associate on the case and the previous history had been that the abortion was the result of a fall. The woman died after a most virulent general peritonitis and the death certificate was duly signed and the cause of death truthfully stated. The certificate was not accepted by the Department of Health, the coroner's office was immediately notified and within a very few hours the District-Attorney was on the trail of the physician as well as on that of the sanatorium authorities. The head of the latter escaped immediate arrest and imprisonment only through the good offices of her legal adviser. On learning of this, Dr. Kosmak on the following day presented himself to the coroner and together with the nurses and all those who had anything to do with the case, was subjected to a most extensive and exasperating questioning. The District-Attorney's representative seemed to take it for granted that the mere word "curettage" signified a criminal abortion, and that its performance immediately put the operator in a position which was in conflict with the law on the subject. Some months later the inquest was held and notwithstanding the false testimony introduced by the police officers and the most unscientific report of an autopsy by one of the coroner's physicians, the jury exonerated all those whose names had been connected with the affair. A marked contrast was shown in the amount of energy expended to annoy and insult those who were legitimately connected with the case and in the effort made to find out those who originally induced the abortion, if this was actually done. Notwithstanding this disagreeable personal experience, Dr. Kosmak felt that the physician's first duty in a case of this kind was towards the patient and that it was not his affair how the process had been started.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

Board of Medical Examiners, North Dakota.

April 4, 1911.

ANATOMY.

Answer any five questions:

1. Give the blood supply of the stomach.
2. Outline the heart on the chest wall, giving location of valves.
3. Describe the scrotum with its contents.
4. Describe the lumbar plexus.
5. Give plan of relations between radial and ulnar arteries.
6. Describe the bladder.
7. Describe the lymphatics of the upper extremity.
8. Name the bones of the face.
9. Outline the liver on external surface.
10. Give the relations of the gall-bladder.

HISTOLOGY.

1. Describe blood-corpuscles.
2. Diagram a section of bone and name structures.
3. Give the histology of the skin.
4. Give the histology of the kidneys.
5. Diagram a section of an artery and name structures.

PHYSIOLOGY.

Answer any five questions.

1. How is the regulation of the temperature of the body effected?
2. What is the function of the blood?
3. Describe the respiratory function.
4. What is the normal composition of the urine?
5. Describe the process of digestion.
6. What is the normal pulse rate and what variations are common in disease?
7. Describe the process of ovulation.
8. Describe the portal blood circulation.
9. What is the function of the cerebellum?
10. Define animal life.

CHEMISTRY AND TOXICOLOGY.

1. Distinguish between synthetic and analytic reactions.
2. Give chemical name and formula of (*a*) lunar caustic, (*b*) caustic potash.
3. Give chemical test for pus and mucus in the urine.
4. What do you understand by chemical action? Give examples.
5. Give yeast test for sugar in the urine.
6. Give the chemical antidote for nitrate of silver.
7. Give symptoms and treatment of chronic lead poisoning.
8. Symptoms of poisoning by opium, belladonna, carbolic acid, and caustic potash. Outline treatment in each case.
9. Treatment of poisoning by stramonium, cocaine, and Indian hemp.
10. Give the symptoms of strychnine poisoning.

MATERIA MEDICA.

1. Give source, dose, and therapeutic indications for strychninæ sulphas.
2. Give derivation, dose, and indications for atropinæ sulphas.
3. In case of fermentative diarrhea what result would you expect from the use of magnesium sulphate?
4. Give officinal name and dosage of (*a*) tartar emetic; (*b*) glauber salts; (*c*) calomel.
5. Give the symptoms and treatment of poisoning by corrosive sublimate.

PATHOLOGY.

1. Define (*a*) leucocytosis; (*b*) phagocytosis; (*c*) regeneration; (*d*) necrosis.
2. Describe the pathological conditions in alcoholic cirrhosis of liver.
3. Describe the lesions of typhoid fever.
4. Pathology of (*a*) chronic interstitial nephritis; (*b*) chronic parenchymatous nephritis.
5. Tell what you know about the formation of a tubercle, also the changes which it undergoes.

PRACTICE.

1. Symptoms and treatment in full for colitis.
2. Differentiate between carcinoma of the liver and hepatic abscess.

3. Diagnose a case of duodenal ulcer and give your treatment in full.
4. Describe the changes occurring in lung tissue in lobar pneumonia; symptoms and treatment.
5. Causes, symptoms, and treatment of empyema.
6. Symptoms and treatment in full of chronic interstitial nephritis.

OBSTETRICS.

1. Describe your first case of labor.
2. What is the occasion of version and how is external version before labor performed?
3. The induction of premature labor, is it ever necessary, and what are the indications for doing so?
4. When should a miscarriage be induced?
5. Give your method of removing the placenta after a normal labor and describe the attention you give the mother and child respectively.
6. What complications may arise after the birth of the foetus?

DISEASES OF WOMEN AND CHILDREN.

1. Give diagnosis and treatment of cystocele.
2. Give symptoms of laceration of the cervix of long standing.
3. Give causes, diagnosis and treatment of acute salpingitis.
4. What is dysmenorrhœa? Give causes and treatment.
5. Describe an operation for repair of ruptured perineum.
6. Diagnosis and treatment of scarlet fever.
7. Give your method of feeding a three months old infant deprived of mother's milk.
8. How would you treat a case of dysentery in a child?
9. Symptoms and treatment of capillary bronchitis.
10. Treatment for constipation in infants.

SURGERY.

1. What is a hydrocele? Give diagnosis and treatment.
2. Give diagnosis and treatment of empyema.
3. Give diagnosis and treatment of acute osteomyelitis.
4. What is surgical shock and how would you treat it?
5. Describe the different dislocations of the shoulder joint and give methods of reduction.

NERVOUS DISEASES.

1. Give the general causes and reflex cause of neuralgia.
2. Differentiate between (*a*) neuralgia and the headache of anæmia; (*b*) neuralgia and osteoscopic pains; (*c*) neuralgia and clavus hystericus.
3. What effect has idleness on epileptics? Does labor aggravate the trouble? Your advice as to marriage to those who become epileptic at puberty; what treatment is effective?
4. What is chorea, its etiology, pathology, diagnosis, prognosis, treatment?
5. What are the causes of paralysis and how many kinds are there? What is the origin of hemiplegia? Paralysis follows what infectious diseases?

PREVENTIVE MEDICINE.

1. Give cause of infantile paralysis and your measures to prevent its spread.
2. How long would you quarantine a diphtheria case and how prevent infection of others?
3. What prophylactic measures do you use in the care of a typhoid case?
4. Define smallpox, giving incubation period and discuss value of vaccination of exposed persons.
5. What is your method of disinfection in case of scarlet fever, before lifting quarantine?

MEDICAL JURISPRUDENCE.

1. By what authority does the State Board of Medical Examiners for the State of North Dakota organize and act, and what are their duties and powers?
2. What is malpractice, and give the statutory limitation for the prosecution of an action against a physician and surgeon for malpractice in this State.
3. Has the Governor of this State power to revoke the license of a physician and surgeon practising medicine and surgery in this State without consulting with or obtaining approval of the State Board of Medical Examiners?
4. What is the penalty for practicing medicine and surgery in this State without first obtaining a lawful license from the State Board of Medical Examiners authorizing the recipient to practice medicine and surgery in the State?
5. What is the duty of an attending physician in cases of attendance upon patients afflicted with contagious diseases; in case of death of patients; and in respect to births, as fixed by the statute in this State?

EYE AND EAR.

1. Causes, symptoms, and treatment of ophthalmia neonatorum.
2. Causes, symptoms and treatment of iritis.
3. Causes, symptoms and treatment glaucoma.
4. Treatment of blepharitis marginalis.
5. Define astigmatism, myopia, hypermetropia, diplopia and chalazion.
6. Treatment of acute otitis media.
7. Symptoms and treatment acute mastoiditis.
8. How do you remove foreign bodies from the ear?
9. How relieve pain in furunculosis of auditory canal?
10. Describe fully effect of nasopharyngeal adenoids upon the ear, and its function.

ANSWERS TO STATE BOARD EXAMINATION QUESTIONS.

BOARD OF MEDICAL EXAMINERS, NORTH DAKOTA.

April 4, 1911.

ANATOMY.

1. *Blood supply of stomach:* Gastric, pyloric, right and left gastroepiploic, and vasa brevia arteries.
2. A line from the lower border of the second left costal cartilage (one inch from sternum) to upper border of third right costal cartilage represents the *base line;* the *right side* will be a line drawn from right side of upper limit to seventh right chondrosternal articulation; the *lower limit* is a line from this last point to the apex (in fifth intercostal space, three and one-half inches from midline); the *left side,* from left end of upper border to left of apex. The valves are: Aortic, mitral, tricuspid, pulmonary (and Eustachian and coronary).

The *aortic valves* are behind the third intercostal space, close to the left side of the sternum. *Pulmonary valves,* in front of the aortic, behind the junction of the third rib, on the left side, with the sternum. *Tricuspid valves,* behind the middle of the sternum, about the level of the fourth costal cartilage. *Mitral valves* behind the third intercostal space, about one inch to the left of the sternum.

3. See Cunningham's "Anatomy" (1909), pages 1159 and 1169; or Gray's "Anatomy" (1910), page 1374.
4. See Cunningham's "Anatomy" (1909), page 641; or Gray's "Anatomy" (1910), page 1047.
5. See Cunningham's "Anatomy" (1909), pages 831 and 834; or Gray's "Anatomy" (1910), pages 646 and 650.
6. See Cunningham's "Anatomy" (1909), page 1144; or Gray's "Anatomy" (1910), page 1360.
7. See Cunningham's "Anatomy" (1909), page 913; or Gray's "Anatomy" (1910), page 784.
8. *Bones of the face:* Two nasal, two superior maxillary, two lacrymals, two malars, two palates, two inferior turbinates; vomer and inferior maxillary.
9. See Cunningham's "Anatomy" (1909), pages 1268 and 1269.
10. The *gall-bladder* is placed in a fossa on the under surface of the right lobe of the liver. Its upper surface is attached to the liver, and its fundus and posterior surfaces are invested by peritoneum reflected from the adjacent surface of the liver. The body is in relation in front with the liver, and behind with the first part of duodenum, the pylorus, and the hepatic flexure of colon. The fundus is in contact with the parietes opposite the ninth right costal cartilage.

HISTOLOGY.

1. The red corpuscles are biconcave discs, about 1-3200 of an inch in diameter; they are nonnucleated, and there are about 4,500,000 or 5,000,000 of them in each cubic millimeter of blood. They are elastic and soft, and their shape is changed by pressure, but is promptly regained on the removal of the pressure. Their color is yellowish. They contain hemoglobin. They carry oxygen from the lungs to the tissues. The *white* blood cells are spheroidal masses, varying in size, having no cell wall, and containing one or more nuclei; there are about 7,000 to 10,000 of them in each cubic millimeter of blood. They differ much in appearance, and are divided into (1) small mononuclear leucocytes, or lymphocytes; (2) large mononuclear; (3) transitional; (4) polynuclear, or polymorphonuclear, or neutrophile, and (5) eosinophile. They are all more or less granular, particularly the last two varieties named. They are probably formed in the spleen lymphatic glands, and lymphoid tissues. There are also *platelets,* which are very small, colorless, irregular shaped bodies; they are about one-fourth the diameter of a red corpuscle. Their function is not determined: it is possible that they take some part in the coagulation of the blood. In number they vary from about 200,000 to more than 500,000 in each cubic millimeter of blood.
2. See Cunningham's "Anatomy" (1909), page 71; or Gray's "Anatomy" (1910), page 37.

3. See Cunningham's "Anatomy" (1909), page 772; or Gray's "Anatomy" (1910), page 1153.

4. See Cunningham's "Anatomy" (1909), page 1139; or Gray's "Anatomy" (1910), page 1352.

5. See Cunningham's "Anatomy" (1909), page 781; or Gray's "Anatomy" (1910), page 576.

An *artery* consists of three coats: The tunica interna, or internal coat; the tunica media, or middle coat, and the tunica adventitia, or external coat. The internal coat consists of a basement membrane, on which is a layer of endothelial cells. The middle coat consists of involuntary muscle fibers, between the layers of which are some elastic fibers. The external coat consists of connective tissue (white fibrous and yellow elastic). Between the two outer coats is an elastic membrane.

PHYSIOLOGY.

1. The variation of body temperature, in health, is very slight; it is maintained between 98° and 99° F.

The normal temperature of the body is *maintained* by the thermotactic centers in the brain and cord keeping an equilibrium between the heat gained or produced in the body and the heat lost.

Heat is produced in the body by: (1) Muscular action; (2) the action of the glands, chiefly of the liver; (3) the food and drink ingested; (4) the brain; (5) the heart; and (6) the thermogenetic centers in the brain, pons, medulla, and spinal cord.

Heat is given off from the body by: (1) The skin, through evaporation, radiation, and conduction; (2) the expired air; (3) the excretions—urine and feces.

2. The *red corpuscles* supply the tissues with hemoglobin; the *white corpuscles* serve as a protection to the body from the incursions of pathogenic microorganisms, they take some part in the process of the coagulation of the blood, they aid in the absorption of fats and peptones from the intestine, and they help to maintain the proper proteid content of the blood plasma.

The *functions of the blood as a whole* are: To distribute nourishment, oxygen, and the internal secretions to the tissues of the body; to remove carbon dioxide and other waste matters from the tissues so that they may be excreated by the lungs, kidneys, and skin; to regulate the body temperature.

3. Respiration means the taking in of oxygen and the elimination of carbon dioxide. The respiratory act consists of inspiration and expiration. The origin of the impulses is at the respiratory center in the medulla. The phrenics and intercostals are the chief nerves conveying the impulses; and they are distributed to the diaphragm and intercostal muscles, respectively. External respiration is the interchange that takes place between the blood and the gases in the lungs; internal respiration is the interchange that takes place between the blood and the tissues of the body. Respiration causes changes in the air as follows:

	EXPIRED AIR.	INSPIRED AIR.
Oxygen	16.6 per cent.	21 per cent.
Nitrogen	79 per cent.	79 per cent.
Carbon dioxide	4.4 per cent.	0.04 per cent.
Other gases	Often present.	Rare.
Watery vapor	Saturated.	Variable.
Temperature	That of body.	Variable.
Volume	Diminished.	Varies.
Bacteria	None.	Always present.
Dust	None.	Always present.

4. The following table (from Dunglison's "Medical Dictionary") gives the average composition of normal urine:

	(PARTS IN 1000.)		VOIDED PER DAY.	
			Grains.	*Grams.*
Water	950.00

5. The process of digestion is carried on by various enzymes:

DIGESTIVE SECRETION.	ENZYMES.	ACTION.
Saliva	Ptyalin.	Changes proteids into dextrin and sugar.
Gastric juice	Pepsin.	Changes proteids into proteoses and peptones in an acid medium.
	A curdling ferment.	Curdles the casein of milk.
Pancreatic juice	Trypsin.	Changes proteids into proteoses and peptones, and afterwards decomposes them into leucin and tyrosin; in an alkaline medium.
	Amylopsin.	Converts starches into maltose.
	Steapsin.	Emulsifies and saponifies fats.
	A curdling ferment.	Curdles the casein of milk.

The products of digestion find their way into the blood by two routes: (1) By the blood-vessels of the gastro-intestinal tract, which unite to form the portal vein, and (2) by the lymph vessels of the small intestine, which converge to empty into the thoracic duct. The water, inorganic salts, proteids, and sugar go by way of the portal vein to the ascending vena cava; the fats go by way of the thoracic duct to the junction of the left subclavian and internal jugular veins.

6. The normal pulse rate is about 70 to 80 per minute for adults. In fevers, as a rule, the pulse is increased about 8 to 10 beats per minute for each degree of body temperature above the normal. Rapid pulse is also found in exophthalmic goiter, myocarditis, endocarditis, pericarditis, neurasthenia. The pulse may be slowed in epilepsy, melancholia, insanity, some brain diseases, and jaundice.

7. See Williams' "Obstetrics" (1909), page 83; or Hirst's "Obstetrics" (1909), page 61.

8. See Cunningham's "Anatomy" (1909), pages 1120 and 902; or Gray's "Anatomy" (1910), pages 1327 and 754.

9. The *functions of the cerebellum* are: To preserve equilibrium, to coordinate muscular movements; it is also, probably, the organ of muscular sense.

10. *Animal life* is defined as: "The manifestations depending directly on the cerebrospinal nervous system and the voluntary muscles, as distinguished from vegetative life—that is, the functions of digestion, respiration, reproduction, etc."—(Gould.)

CHEMISTRY AND TOXICOLOGY.

1. *Analysis* is the splitting up of a compound into simpler compounds or into elements: $2KClO_3 = 2KCl + 3O_2$.

Synthesis is the formation of compounds from simpler compounds or from elements: $2H_2 + O_2 = 2H_2O$.

2. (*a*) *Lunar caustic* is silver nitrate, $AgNO_3$. (*b*) *Caustic potash* is potassium hydroxide, KHO.

3. *Pus:* The addition of an equal quantity of a solution of potassium hydroxide to urine containing pus gives rise to the formation of a viscid gelatinous mass.

Mucus: If urine containing mucus is treated in the same way (with potassium hydroxide) the mucus is dissolved.

4. By *chemical action* is meant the mutual action of substances upon each other when they are brought in contact under proper conditions. When this occurs certain changes in composition ensue; the first substances disappear and new substances take their places. The kinds of chemical action are:

(1) *Combination,* or *synthesis;* as when $2H_2 + O_2 = 2H_2O$.

(2) *Decomposition,* or *analysis;* as when $2HgO = 2Hg + O_2$.

(3) *Double decomposition,* or *metathesis;* as when

$$BaCl_2 + H_2SO_4 = BaSO_4 + 2HCl.$$

(4) *Atomic rearrangement;* as when ammonium isocyanate is converted into urea:

$$(NH_4)\,CNO = CO\,(NH_2)_2.$$

5. Three Smith's fermentation tubes are used, each containing a little compressed yeast, one filled with the liquid to be tested, the second with pure water, and the third with a dilute solution of glucose, and the three are put in a warm place over night. If gas collects in the first and

third tubes, but not in the second, the liquid contains sugar; if gas collects in the third only it does not; under any other circumstances the yeast is at fault.

6. The chemical antidote for nitrate of silver is a solution of salt in water.

7. *The symptoms of poisoning by lead* are: "Metallic taste; dryness of the throat; thirst; severe colicky abdominal pains, referred particularly to the umbilical region, and relieved by pressure; pulse very feeble and slow; great prostration; constipation; urine scanty and red; violent cramps; paralysis of the lower extremities; convulsions and tetanic spasms."

The *treatment* consists in removing the cause and administering the antidote, "magnesium sulphate, which brings about the formation of the insoluble lead sulphate, while the purgative action of the magnesia is also useful. It should be preceded by an emetic or by the use of the stomach tube."—(Witthaus' *Essentials of Chemistry.*)

8. *Opium poisoning: Symptoms:* In opium poisoning there may be three stages: (1) a period of excitement, in which the patient is active, talkative, and has hallucinations; (2) a period of drowsiness, in which the patient is sleepy, but may be aroused; his face is pale, lips livid, pupils contracted; this passes into (3) the stage of coma, from which the patient cannot be aroused, the reflexes are abolished, the pupils are very contracted, the pulse is slow and irregular, and the respirations are infrequent and shallow.

Treatment consists in washing out the stomach, preferably with a dilute solution of potassium permanganate; ambulatory treatment, to keep the patient awake; artificial respiration is indicated, and strong coffee should be administered by the mouth or rectum; the bladder should be emptied by the catheter.

Symptoms of poisoning by belladonna: "In the first stage, that of delirium, there are dryness of the throat, thirst, difficulty of deglutition and spasms upon swallowing liquids, face at first pale, afterwards highly reddened, pulse extremely rapid, eyes prominent, brilliant with widely dilated pupils, complete paralysis of accommodation, disturbances of vision, attacks of giddiness and vertigo, with severe headache, followed by delirium, occasionally silent or muttering, but usually violent, noisy, and destructive, accompanied by the most fantastic delusions and hallucinations. Usually the urine is retained, and the body temperature is above the normal. The delirium gradually subsides, and the second stage, that of coma, is established, with slow, stertorous respiration, and gradually failing pulse, until death occurs from respiratory or cardiac paralysis, or sometimes in an attack of syncope during apparent amelioration."

Treatment: "Lavage of the stomach; morphine may be given cautiously during the period of violent excitement. Maintain respiration; strong coffee by the mouth or rectum is beneficial. Pilocarpine may be given, in not too large doses, to stimulate the secretion of saliva."—(From Witthaus' *Essentials of Chemistry.*)

Symptoms of carbolic acid poisoning: Buccal mucous membrane is whitened and hardened; vomiting; burning pain in mouth, esophagus, and stomach; pulse and body temperature are lowered; the pupils are contracted; collapse, and finally death. The urine may become dark.

Treatment: Emetics, white of egg, stimulants. Alcohol is said to be antidotal.

Caustic potash, symptoms: Soapy taste in mouth, followed by a burning taste, vomiting of alkaline material, eschars on skin, lips, and tongue. *Treatment:* Give vinegar or a weak acid, oils and milk; do *not* use the stomach pump.

9. For *stramonium*, treatment is same as for belladonna; see QUESTION 8. For *cocaine*, ammonia or coffee should be administered; morphine, strychnine, chloroform, and ether have all been suggested. The safest plan is to treat whatever symptoms are present. Amyl nitrite is said to be antidotal. For *Indian hemp* give strychnine, empty the stomach, and then stimulate.

10. The *symptoms of poisoning by strychnine* are as follows: "Strychnine produces a sense of suffocation, thirst, tetanic spasms, usually opisthotonos, sometimes emprosthotonos, occasionally vomiting, contraction of the pupils during the spasms, and death, either by asphyxia during a paroxysm, or by exhaustion during a remission. The symptoms appear in from a few minutes to an hour after taking the poison, usually in less than twenty minutes; and death in from five minutes to six hours, usually within two hours.

MATERIA MEDICA.

1. STRYCHNINÆ SULPHAS. *Source:* Strychnos nux vomica. *Dose:* gr. 1/64 to 1/16. *Therapeutic indications:* As a general tonic or bitter; in indigestion, cardiac depression, impaired peristalsis, pneumonia, phthisis, amenorrhea, dysmenorrhea, impotence, some forms of paralysis, chorea, epilepsy, neuralgia, alcoholism, and urinary incontinence.

2. ATROPINÆ SULPHAS. *Source:* Atropa belladonna. *Dose:* gr. 1/250 to 1/40. *Indications:* For the relief of pain, to dilate the pupil, to check secretions, for diarrhea, for asthma, for shock and collapse, for colic of all kinds, for delirium, for epilepsy, chorea and migraine, for paralysis, for cough, in constipation, in chorea, spermatorrhea, or cystitis.

3. Good purgative effect, with abstraction of fluid from the intestinal blood-vessels, together with increased peristalsis.

4. *Tartar emetic:* Antimonii et potassii tartras, dose gr. 1/10 to ½. *Glauber salts:* Sodii sulphas, dose about ʒiv. *Calomel:* Hydrargyri chloridum mite, dose about 1 gr.

5. The *characteristic symptoms of poisoning by corrosive sublimate* are: A burning pain in the mouth, pharynx, and stomach; the mouth and tongue are white; the vomitus is white, with shreds of mucous membrane, and tinged with blood; bloody stools, also salivation may occur.

Treatment: The antidote is white of egg, but too much must not be given at one time; this should be followed by an emetic.

PATHOLOGY.

1. *Leucocytosis* is a condition in which the leucocytes are increased in number. *Phagocytosis* is the ingestion of bacteria or other foreign particles by certain cells (chiefly white blood corpuscles). *Regeneration* is the process of repair of diseased or lost structures. *Necrosis* is death of tissues.

3. See French's "Practice of Medicine" (1910), page 70; or Osler's "Practice of Medicine" (1909), page 65.

4. See French's "Practice of Medicine" (1910), pages 925 and 918; or Osler's "Practice of Medicine" (1909), pages 695 and 692.

5. See French's "Practice of Medicine" (1910), page 342; or Osler's "Practice of Medicine" 1909), page 295.

PRACTICE.

1. See French's "Practice of Medicine" (1910), pages 832 and 793; or Osler's "Practice of Medicine" (1909), page 530.

2. See French's "Practice of Medicine" (1910), pages 853 and 858; or Osler's "Practice of Medicine" (1909), pages 564 and 569.

3. See French's "Practice of Medicine" (1910), page 765; or Osler's "Practice of Medicine" (1909), page 473.

4. See French's "Practice of Medicine" (1910), pages 154, 156 and 174; or Osler's "Practice of Medicine" (1909), pages 170, 172 and 189.

5. See French's "Practice of Medicine" (1910), page 711; or Osler's "Practice of Medicine" (1909), page 648.

6. See French's "Practice of Medicine" (1910), pages 927 and 932; or Osler's "Practice of Medicine" (1909), pages 697 and 700.

OBSTETRICS.

2. *Indications for version* are: (1) In transverse presentations; (2) in placenta prævia; (3) in malpresentations of the head; (4) in simple flattened pelvis, and in minor degrees of pelvic contraction; (5) in prolapsed funis; (6) in sudden death of the mother, and (7) in any case where speedy delivery is imperative. And see Williams' "Obstetrics" (1909), page 432; or Hirst's "Obstetrics" (1909), page 829.

3. *Conditions warranting the induction of premature labor:* (1) Certain pelvic deformities, (2) placenta prævia, (3) pernicious anemia, (4) toxemia of pregnancy, (5) habitual death of the fetus toward the end of pregnancy, (6) hydatidiform mole, (7) habitually large fetal head.

4. See Williams' "Obstetrics" (1909), page 373; or Hirst's "Obstetrics" (1909), page 797.

5. See Williams' "Obstetrics" (1909), pages 298, 340 and 346, etc.; or Hirst's "Obstetrics" (1909), pages 342, 365, 928, etc.

6. Retained placenta, post-partum hemorrhage, sepsis, subinvolution, embolism, thrombosis, death of mother, eclampsia.

DISEASES OF WOMEN AND CHILDREN.

1. *Cystocele* is a hernia of part of the bladder into the vagina, covered by the mucous membrane of the anterior vaginal wall. *Symptoms:* A dragging sensation in the lower pelvic cavity; a feeling of distention at the vulva; loss of power in urination; tumor of anterior vaginal wall, more apparent on straining; prolapse of uterus. It is often accompanied by rectocele.

For radical cure of cystocele: "The patient is placed in dorsal position. The posterior vaginal wall is kept out of the way with a weighted speculum. The cervix is drawn down with a bullet-forceps. With a pair of tenacula the sides of the prominence are drawn together in the median line in order to see how much of the wall is redundant and these points are marked with small nicks. Next, the whole surface is put on the stretch between four pairs of forceps —one at each of the sidemarks, one near the cervix, and one at the transverse ridge at the inner end of the urethra. With a pair of scissors curved on the flat, a strip about ¼ inch wide is cut out of the mucous membrane. Similar strips are removed on both sides until an oval is denuded. Finally a running suture of chromicized catgut is passed under the whole pared surface, uniting the edges from side to side." If necessary, a perineorraphy should be done at the same time.

2. Laceration of the cervix may cause hypertrophy, elongation, sclerosis, cystic degeneration, or carcinoma of the cervix; subinvolution, or displacements of the uterus, also endometritis. Other results may be pain on walking, on defecation, or during coitus; sterility or abortion; headaches, backache, neuralgic pains, neurasthenia, indigestion, constipation.

3. Salpingitis. *Etiology:* Septic infection, gonorrhea, menstrual congestion, taking cold at the menstrual periods. *Diagnosis:* Pain in ovarian region; fever; rapid pulse; local tenderness; pain on moving, walking, defecation, coitus, and during menstruation; menorrhagia and sterility; the enlarged tube may be palpated by vaginal examination. *Treatment:* Rest in bed, hot vaginal douches, saline purgatives, liquid diet, morphine (if necessary) for pain, removal of pathological conditions and complications; radical operation (salpingectomy, or salpingo-oophorectomy) may be necessary.

4. Dysmenorrhea is painful menstruation. *Causes:* Pelvic congestion, pelvic inflammation, malnutrition, overwork, lack of develpment, neuralgia, stenosis, or obstruction of the cervix prolapse, or displacement of the uterus. *Treatment:* If possible remove cause; attend to the general condition, hygiene, tonics, regular habits, etc.; curettage may be necessary, and may have to be repeated (perhaps more than once).

5. See Williams' "Obstetrics" (1909), pages 325, etc.; or Hirst's "Obstetrics" (1909), pages 867, etc.

6. See French's "Practice of Medicine" (1910), pages 317, 322 and 324; or Osler's "Practice of Medicine" (1909), pages 132, 136 and 138.

7. For a child three months old:

℞. Cream ℥ss (one tablespoonful)
Milk ℥jss (three tablespoonfuls)
Water ℥jss (three tablespoonfuls)
Milk sugar ℥j (one teaspoonful)
Salt gr. v. (a pinch).

Feed every two and a half hours.

8. See French's "Practice of Medicine" (1910), page 258.

9. See French's "Practice of Medicine" (1910), pages 688 and 690; or Osler's "Practice of Medicine" (1909), pages 624 and 626.

10. See French's "Practice of Medicine" (1910), page 825; or Osler's "Practice of Medicine" (1909), page 528.

SURGERY.

1. See Rose and Carless' "Surgery" (1908), page 1265; or Da Costa's "Surgery" (1908), page 1201.

2. The physical signs are those of fluid in the pleural cavity; that side does not move well, the percussion note is dull, there is absence of breath sounds, vocal fremitus and resonance are diminished. Left alone, an empyema may burst through an intercostal space, usually the fifth. The lung is collapsed in extent according to the amount of pus. The pleura, at first covered with lymph, soon becomes covered with layers of granulation tissue, the deeper part of which is converted into fibrocicatricial tissue, and the lung itself also undergoes some fibroid change. If the pus is let out early the lung and pleura soon expand, but if allowed to go on the infiltration of the lung and the density of the scar tissue covering it hinder expansion. Nature attempts to remedy this in various ways. (1) The other lung expands and pushes the heart over to the opposite side; (2) the chest wall falls in, the intercostal spaces are obliterated, and the spine is curved, with its concavity toward that side; (3) the abdominal viscera are pushed up; and (4) exuberant granulations form on the pleura. If a cavity still remains an operation is necessary.

Symptoms: Fever, sweats, chill, diminished breath sounds and vocal fremitus, impaired mobility of chest, dullness on affected side, heart displaced to opposite side, leucocytosis; aspiration shows pus.

Treatment: Aspiration, drainage, irrigation, resection of ribs (Estlander's operation), or resection of chest wall (Schede's operation).

3. Osteomyelitis. *Symptoms:* Sudden onset; pain, tenderness, fever, chills, swelling of soft parts; sometimes the joint can be moved gently without pain; septicemia or pyemia, may be present.

It is to be *diagnosed* from (1) *Rheumatism,* in which more than one joint is affected and the tenderness is *in* the joint, and not *near* it. (2) *Tubercular arthritis,* in which the onset is slow and the trouble starts in the epiphysis rather than in the diaphysis. (3) *Cellulitis,* in which the bone and periosteum are not affected, and in which there is always a wound.

In *osteomyelitis,* the *treatment* consists in relieving the constitutional symptoms and preventing the bone from necrosing. An incision down to the bone is made; if pus is beneath the periosteum, the latter is also incised; a piece of bone is removed by chisel or trephine, pus is removed, the endosteum is hurt as little as possible, the wound is irrigated with hot bichloride solution and packed with gauze; the soft parts are closed and the wound well drained. In case this fails, amputation may be necessary.

4. Shock is the name given to a sudden and general depression of the vital powers due to some strong stimulation (such as injury or emotion) acting on the vital centers in the medulla, and producing vasomotor paralysis.

Treatment of shock: Place the patient in the recumbent position, with the head low, apply warmth to the body, administer a stimulant, and give a hot saline infusion; morphine, hypodermically, may be necessary for the relief of pain.

5. The *various dislocations of the shoulder-joint* are: (1) subcoracoid—forward, inward, and downward. (2) Subglenoid—downward, forward, and inward. (3) Subspinous—backward, inward, and downward. (4) Subclavicular—forward, inward, and upward.

The *special diagnostic signs* are: (1) *Subcoracoid:* The head of the humerus is felt below the outer end of the clavicle; there is little or no shortening of the limb; the elbow is directed outward and backward.

(2) *Subglenoid:* The head of the humerus can be felt in the axilla; the arm is decidedly lengthened; the elbow is flexed; and there are signs of pressure on vessels and nerves.

(3) *Subspinous:* The head of the humerus is felt below the acromion process and behind; the arm is rotated inward, and the elbow is displaced outward.

(4) *Subclavicular:* The head of the humerus is felt below the clavicle; the elbow is far from the side; and the limb may be shortened.

Kocher's method of reduction is: to flex the forearm, press the elbow to the side, rotate the arm outward. Bring the arm forward and upward to a right angle with the body, then rotate inward, while the elbow is brought down over the body so that the fingers sweep the opposite shoulder.

NERVOUS DISEASES.

1. *Neuralgia.*—The most important etiological factors are adult life, female sex, heredity, anemia, malaria, syphilis, rheumatism, metallic poisons, gout, anxiety, mental exertion, exposure to cold and damp, injuries to the nerve-trunks, and reflex disturbances such as accompany eye-strain and dental affections.

2. See French's "Practice of Medicine" (1910), page 1019; or Osler's "Practice of Medicine" (1909), page 1069.

Headache from anemia is usually frontal or diffuse, frequently accompanied by a distressing sensation of pressure, and is often associated with vertigo, and in rare instances with tinnitus aurium. In some cases the patient perceives and is greatly annoyed by the systolic murmurs which develop. The headaches are usually intensified by temporary effort. (From Dercum.)

Osteoscopic pains are boring in character, and are always worse at night.

In *clavus hystericus* the pain in the head is circumscribed, is comparable to pain such as would be derived from driving a nail into the part; it may be accompanied with ringing and beating noises in the ears, and there is a feeling of being beaten on the temples with mallets; auræ may be present. (From Dercum.)

In addition, in each of the latter complaints there will be present the symptoms peculiar to anemia, bone disease, and hysteria, respectively.

3. Idleness is bad for epileptics. Labor (in moderation, and not to the point of fatigue) is good for epileptics. Epileptics should be advised against marriage, because: (1) Epilepsy is not as a rule improved by marriage, and (2) the act of marriage is a strong inducement to per-

petuate a race of epileptics. The most effective treatment includes: control of the patient, proper educational measures, colony system of treatment, and systematic outdoor life with as little as possible of sedentary occupation.

4. See French's "Practice of Medicine" (1910), page 1153; or Osler's "Practice of Medicine" (1909), page 1045.

5. "*Paralysis* involving a lateral half of the body is termed *hemiplegia;* when involving the body from the waist down, *paraplegia,* and when involving a single member, *monoplegia.*

"Paralysis may be irregularly distributed and in such cases may be due to localized disease of the muscles or nerves of the affected region, or to syringomyelia, disseminated lesions in the motor area of the brain, lesions of the basal ganglia, and poliomyeletis (acute and chronic).

"*Hemiplegia* usually results from hemorrhage at the base of the brain injuring the internal capsule, corpus striatum, or optic thalamus. The paralysis occurs on the opposite side of the body. As other causes of unilateral paralysis may be mentioned lesions of the motor cortex, crus cerebri, or pons, a unilateral lesion high up in the spinal cord, and hysteria.

"*Paraplesia* may be due to multiple neuritis, caisson disease, or hysteria, but in most cases is the result of injury or disease of the spinal cord such as occurs in fractures or caries of the vertebræ, morbid growths, aneurysm, hemorrhage, acute myelitis, chronic myelitis, Landry's disease, and lateral sclerosis. Injury to the brain during delivery may induce spastic paraplegia.

"*Monoplegia* may result from disease or injury of a peripheral nerve, a focal lesion in the cortex, or from hysteria." (Hughes' *Practice of Medicine.*)

Infectious diseases which may be followed by paralysis: Diphtheria, malaria, cerebrospinal meningitis, syphilis.

PREVENTIVE MEDICINE.

1. Infantile paralysis is probably infectious, but the particular microorganism is not yet isolated. Prevention of its spread demands isolation and quarantine as in case of the infectious diseases such as scarlet fever or diphtheria.

2. See French's "Practice of Medicine" (1910), page 194; or Osler's "Practice of Medicine" (1909), page 207.

3. See French's "Practice of Medicine" (1910), page 107; or Osler's "Practice of Medicine" (1909), page 96.

4. See French's "Practice of Medicine" (1910), pages 298, 301, and 308; or Osler's "Practice of Medicine" (1909), pages 112, 115, and 127.

5. "After the patient has recovered, he may be given a bichloride bath (1 to 2000), and his skin may be anointed with olive oil; he should then be removed to another room, previously well aired, and fresh linen should be provided. After convalescence the room and its contents must be thoroughly disinfected. The preferable method for the contents is by incineration and complete destruction; this is desirable especially for old mattresses, carpets, rugs, hangings, and other articles of little value; articles of value may be subjected to the action of superheated steam (steam under pressure), or boiling water, or chemicals, such as carbolic acid, mercuric bichloride, or formaldehyde. The room itself should be hermetically sealed and subjected to the action of formaldehyde gas, which may be generated in special generators, or by the addition of potassium permanganate to the official formalin, in the proportion of 8 ounces of the permanganate to one pint of the formalin to each 1600 cubic feet of air space. The room should not be opened until after the lapse of twelve to twenty-four hours. Thereupon the floor and other woodwork, etc., should be scsrubbed with hot water and soap and then washed with mercuric bichloride (1 to 500)—which some time after it has dried should itself be washed off. The room then should be exposed for a day or two to a vigorous current of fresh air and as much sunlight as possible. New wall paper should be substituted for the old."—(Kelly's *Practice of Medicine.*)

MEDICAL JURISPRUDENCE.

1. They are appointed by the Governor of the State. They have power to license practitioners of medicine; also to revoke or refuse license for unprofessional, dishonorable or immoral conduct, chronic or persistent drunkenness, the practice of criminal abortion, or for publicly advertising special ability to treat or cure "incurable" diseases.

2. Malpractice is a failure on the part of a medical practitioner to use such skill, care, and judgment in the treatment of a patient as the law requires; and thereby the patient suffers damage. If due to negligence only, it is *civil* malpractice. But if done deliberately, or wrongfully, or if gross carelessness or neglect have been shown, or if some illegal operation (such as criminal abortion) be performed, it is *criminal malpractice.*

As a rule, there is no statute of limitations fixing time within which an action for malpractice must be brought; but generally no such action will lie after a physician has brought suit for his fee.

3. No.

4. Fine of from $50 to $100 or imprisonment in a county jail not exceeding thirty days, or both fine and imprisonment.

5. To report the same to the proper authorities within the specified time.

EYE AND EAR.

1. OPHTHALMIA NEONATORUM. *Causes:* The gonococcus or some other pyogenic microorganism; the secretions of the mother contain the infecting agent, and transmission may occur directly during parturition, or indirectly by the fingers of physician or nurse, cloths, instruments, etc. *Symptoms:* Swollen eyelids, with copious purulent discharge; ulceration of the cornea may ensue. *Prophylaxis:* Whenever there is the possibility of infection, or in every case, wash the eyelids of the newborn child with clean warm water, and drop on the cornea of each eye one drop of a 1 per cent. solution of nitrate of silver, immediately after birth. *Treatment:* Wash the eyes carefully every half hour with a saturated solution of boric acid; pus must not be allowed to accumulate. Two drops of a 2 per cent. solution of nitrate of silver must also be dropped on to the cornea every night and morning. The eyes must be covered with a light, cold, wet compress. The patient must be islated, and all cloths and compresses used must be burnt.

2. IRITIS. *Causes:* Syphilis, rheumatism, gonorrhea, gout, diabetes, leprosy, scrofula, tuberculosis, injury transmission from the eye. *Symptoms:* Pain, photophobia, small pupil, ciliary congestion, discoloration of iris, exudate in anterior chamber. *Treatment:* Causal abstraction of blood from temples, atropine, diaphoresis, shielding the eye from light.

3. *Glaucoma* is a diseased condition of the eye, produced by increased intraocular pressure, and resulting in excavation and atrophy of the optic disc, and blindness. It is due to increase of the contents of the eye, hypersecretion, retention, old age, gout, rheumatism, nephritis, *Symptoms:* Visual disturbances, increased ocular tension, hazy and anesthetic cornea, sluggish and dilated pupil, shallow anterior chamber, ciliary neuralgia, cupping of optic disc, blindness. *Treatment:* Myotics, such as eserine or pilocarpine; massage of the eyeball; mydriatics are contraindicated; operative treatment may include paracentesis, iridectomy, or sclerotomy.

4. *Treatment of blepharitis marginalis:* Remove cause, if possible; remove scales, and keep edges of lids clean and fresh, warm water or weak boric acid solution, or bichloride of mercury 1:5,000; massage; silver nitrate (2 per cent.) on ulcers; epilation of distorted cilia; treat conjunctival or corneal disease.

5. *Astigmatism* is a condition in which, owing to a greater curvature of the eye in one meridian than in others, the refractive power of the eye varies.

Myopia is a condition in which the anteroposterior axis of the eye is abnormally long, and parallel rays are focused in front of the retina.

Hypermetropia is a condition in which the anteroposterior axis of the eye is abnormally short, and parallel rays are focused behind the retina.

Diplopia is a condition in which an object seen appears double.

Chalazion is a tumor in the eyelid, due to obstruction of the duct in a Meibomian gland.

6. *Treatment of acute otitis media:* "The treatment depends upon the symptoms, which are exceedingly variable. When the symptoms are those of middle ear-ache without great exudation, the treatment consists in the inflation of the Eustachian tube, alkaline spray to the post-nasal space, two to three drops of 8 per cent. solution of cocaine, dropped into the ear, and afterwards hermetically sealing the canal with small pledgets of cotton or inserting into the ear a few drops of the following, which will bring immediate results:

℞. Chloralis camphorat., 5 parts.
Glycerini, 30 parts.
Ol. amygdalæ dulcis, 10 parts.

As soon as the pain has disappeared the hyperemia and swelling of the Eustachian tube is quickly reduced by spraying the post-nasal space with alkaline solution, followed by the application of argentum nitrate eight grains to the ounce. The treatment of the external auditory canal

and tympanum consists in dropping three to four drops of solution of zinc sulphate, eight grains to the ounce, into the ear and hermetically sealing with collodion. This is repeated twice daily until all symptoms have passed away. If the pain and effusion into the ear is great, dry hot applications, paracentesis, purging, antipyretics, and rest in bed are indicated. The disease runs its course in from three to ten days."

7. Acute Mastoiditis. *Symptoms:* Tenderness, pain, swelling and redness over the mastoid; bulging of the superior and posterior parts of the auditory canal; temperature variable, from normal up to about 104° F. *Treatment:* Hot water, or cold water, or ice; leeches; purgatives; light diet; acetanilid; incision, or mastoid operation.

8. *Foreign bodies may be removed from ear:* (1) Insects, by warm water or chloroform oil; (2) by syringing carefully; (3) wax may be removed by disintegrating it with hydrogen dioxide, followed by warm water irrigation.

9. Hot applications; cleansing with hydrogen peroxide; morphine, and calcium sulphide, internally; incision.

10. "The presence of adenoid tissue in the vault of the pharynx affects the ear in two ways. If the mass is large by direct pressure upon the Eustachian orifice the supply of air in the tympanic cavity may be disturbed. . . . Any slight increase in the volume of the mass will close the lumen of the tube, after which the intratympanic air is gradually absorbed by the blood which circulates through vessels in the walls of the cavity. With each act of swallowing, at which time the tube opens momentarily, the air is aspirated into the nasopharynx, the tube closing so quickly that the passage of air into the tympanum does not take place. In this manner a passive congestion of the mucous membrane of the middle ear is produced, a condition which constitutes practically the first stage of an inflammation, and, if long continued, results in permanent tissue changes. . . . The more important manner in which adenoid growths affect the organ of hearing is by the obstruction to the venous return current from the tympanum and labyrinth. The pharyngeal tonsil, in virtue of its presence, may exert sufficient pressure to partially obstruct the venous flow from the tympanic cavity. Any condition which affects, for a considerable period, the circulation within the middle ear will also cause a disturbance of the labyrinthine circulation from an alteration in the tension of the fluid contained. Such changes in the labyrinth render it particularly susceptible to inflammation, either as the result of infection or of mechanical irritation, the most fruitful source of the latter being the crowding inward of the ossicular chain by atmospheric pressure, when the tension of air within the tympanum is reduced. . . . There may also be a diminution of bone conduction and a hyperesthetic condition of the auditory nerve." (From Dench's *Diseases of the Ear.*)

Utah.—There is a new Medical Practice Law in this State The fee for reciprocity is $75. Provision is made for the revocation of license for "unprofessional conduct."

Michigan.—The following States are in reciprocity with Michigan: Arkansas, District of Columbia, Georgia, Illinois, Indiana, Iowa, Kansas, Kentucky, Louisiana, Maine, Maryland, Minnesota, Missouri, Nebraska, Nevada, New Hampshire, New Jersey, New York, North Dakota, Ohio, South Carolina, Tennessee, Texas, Utah, Vermont, Virginia, West Virginia, Wisconsin, Wyoming.

Infant Mortality.—Shipley states that ignorance dispelled by knowledge gained and practically applied is, next to breast feeding, the most important factor in reducing the deaths among infants, and too much stress cannot be laid upon it. The eagerness of the Hebrow mothers to learn how to properly care for their children undoubtedly explains to a great degree the remarkably low death rates in the wards inhabited by them.—*New York State Journal of Medicine.*

X-Ray Demonstration of Anomalies of the Colon.—C. Eastmond summarizes the following anomalies of the colon that are revealed by the *x*-rays: General prolapse of the transverse colon producing the "U" or "V" type. Prolapse of the hepatic or splenic flexure with or without angulation. Angulation of any part, especially of the sigmoid. Prolapse of one-half of the entire colon. General prolapse of the entire colon into the pelvis. Spasm of one part or of the entire colon. Anomalous development of any part, such as a loop formation from the presence of an unduly long mesentery. Adhesions, either alone or associated with any of the above conditions.—*Long Island Medical Journal.*

Medical Items.

Meningitis with Mumps.—C. Dopter says that meningitis accompanying mumps is not infrequent; it is generally slight and entirely recovered from, but in a few cases is rapidly fatal. It is found when spinal puncture is made that there is a lymphocytosis of the cerebrospinal fluid Autopsy in fatal cases has shown that there is congestion, and exudation covering the convexity or the base of the brain and surrounding the cranial and spinal nerves. The condition comes on suddenly in the period of defervescence, with fever, headache, stiffness of the neck, and paralysis of the cranial nerves, or neuritic paralysis of the limbs. The prognosis is generally good, but a few cases are rapidly fatal.—*Paris Médical.*

Hydrotherapy in Night Sweats of Tuberculosis.—Strasser notes that if hyperidrosis occurring in phthisis is to be regarded as the consequence of a weakening in or change of the mechanism regulating the sweat glands, produced by the specific proteins, then hydrotherapy receives a rational explanation on the basis of its recognized power in combating toxemia.—*Zeitschrift für physikalische und diätetische Therapie.*

Health Reports.—The following cases of and deaths from smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended June 9, 1911.

THE VACCINE TREATMENT OF TYPHOID FEVER.*

By JAMES G. CALLISON, M.D.,

INSTRUCTOR IN CLINICAL MICROSCOPY AND VACCINE THERAPY, NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

During the past two summers I have been treating with vaccines all such cases of typhoid fever as came under my observation and in which permission could be secured. In the earlier part of this work the dosage used was small: three or four injections of 25,000,000 each. The plan later followed has been gradually to increase the dosage, carefully watching each patient for any symptom, favorable or unfavorable, which could be attributed to the vaccines. In this way the dosage has been increased until at present four or more injections of 500,000,000 each are given at intervals of two or three days. It is to note the results of the treatment, and to attempt to draw some conclusions therefrom, that this paper has been prepared.

Before reporting the cases treated some discussion of prophylactic vaccination and its relation to the development of antibodies, as well as of the method of natural recovery from typhoid, seems advisable.

In prophylactic vaccination the most common procedure, that followed in the United States Army, is to give three doses: an initial injection of 500,000,000 and two successive injections of 1,000,000,000 each at intervals of ten days. The development of antibodies in demonstrable quantities begins on the fifth to tenth day thereafter, usually about the eighth. The most important of these are the bacteriolysins and opsonins, and together with these there develop large amounts of agglutinins, playing an unknown part in immunity; the two last—opsonins and agglutinins—can be taken as a measure of the antibodies present, as the quantitative relations of the three seem to be quite constant.

Russell has made extensive determinations of the two principal antibodies—the agglutinins and the opsonins—showing the amounts and time of formation. His work is uniform, reliable, the latest on the subject, and covers a long period of time. As a complete understanding of this subject is necessary in order to interpret the results of treatment, I quote from him at length:[1]

"Examination of the blood serum after vaccination has been made of a large number of cases, and as the results are, as a rule, quite similar, the exhibition of three charts—I, II, and III—will suffice as examples. They are neither better nor worse than many others, and are offered here merely because they cover a greater period of time and greater number of examinations than any others which have been made. The men were vaccinated in March and June, 1909, and weekly observations on the agglutination and on the phagocytosis have been made regularly. No curve of the bactericidal power is shown, for we have not yet been able to get any method which will give *in vitro* altogether satisfactory results over a long period.

"All agglutinations are done by the macroscopic method, and the serum dilutions are made with great care and can be considered quite accurate. An increase in the agglutination is often evident on the fourth or fifth day, and by the sixth or eighth day a considerable increase is always noted. The curve shoots up rapidly to 1-10,000 and even 1-20,000. The fall begins in about six weeks and continues to approach normal more or less slowly, so that at the end of fifteen months in my oldest case it is not evident in dilutions above 1-80 to 1-100. In exceptional cases the curve is neither so high nor so long as that exhibited. The curve of phagocytosis is equally well marked. The rise is sharp and high and the titre reached is usually 1-5,000. It falls more rapidly than the agglutination curve, but even after ten months in the oldest case it has not yet dropped to normal. We encountered rather more trouble in developing a satisfactory routine technique for this test than for the agglutinations, and our observations consequently do not go so far back. The opsonic index when taken by ordinary method, fails completely and the dilution method of Neufeld is therefore used. At first the capillary pipettes of Wright, and human leucocytes, were made use of with progressive dilutions of the serum and salt dilutions and normal serum controls. The titre of the serum is expressed by the highest dilution in the final mixture, which showed more phagocytosis than the controls. Thus the primary serum dilution, 1 in 10, 1 in 100, would become diluted with equal volumes of leucocytes and bacterial emulsion, 1 in 30, 1 in 300, etc. By this method a rapid inspection of the slides eliminates all dilutions in which the phagocytosis is marked, and only the controls and those slides on the border line remain to be counted. In the last few months we have adopted the Neufeld method *in toto*, since in practice it takes much less time and is quite simple. The leucocytes are obtained from guinea-pigs after aleuronat injections into the peritoneal cavity, and the mixture of leucocytes, serum, and bacteria is made in small test tubes. The serum is inactivated at 56° C. for thirty minutes, and the mixture is incubated for two hours at 37° C., when the smears are made and stained with a polychrome methylene blue.

"We have found the strain of typhoid bacillus to be very important. All our old cultures, and even many recently isolated ones, are phagocyted spontaneously to such an extent that little difference can be seen between the controls and the serum to be tested. After searching through all our

*Read before the Medical Association of the Greater City of New York, May 15, 1911.

stock cultures and many recent isolations we selected strains obtained by blood cultures in the early stages of typhoid fever which are almost completely resistant to spontaneous phagocytosis, and these strains have been transferred at infrequent intervals, and only one out of the several selected has since degenerated to the same condition as the older cultures. With a suitable culture of typhoid, guinea-pig leucocytes, and a rather long period of incubation, we found no difficulty in getting regular and well-marked determinations of the phagocytic power of the serum."

Charts I, II, and III are reproduced from Russell's work.

Chart I[2] is that of a man who received the first inoculation June 1, 1909. Determinations made June 11 show no increase in agglutinins and opsonins. After that there is a rapid increase, so that

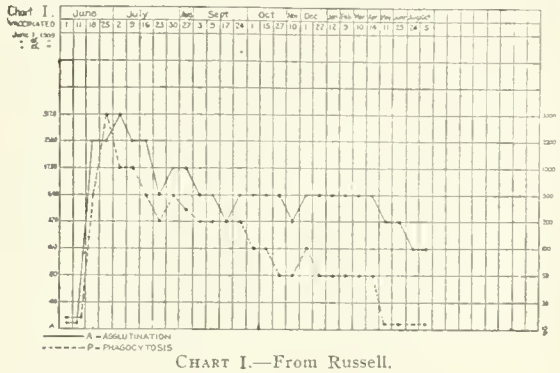

CHART I.—From Russell.

on the 18th the agglutinins are effective in a dilution of 1 to 2,560 and the opsonins in a dilution of 1 to 500. Thereafter the agglutinins increased only slowly; but on the 25th there is phagocytosis in a dilution of 1 to 3,000.

Chart II[1] is that of a soldier on whom frequent determinations were made from March 6 to April 23, showing normal phagocytosis. On April 24 he received the initial inoculation, and on April 30 phagocytosis and agglutination were still normal.

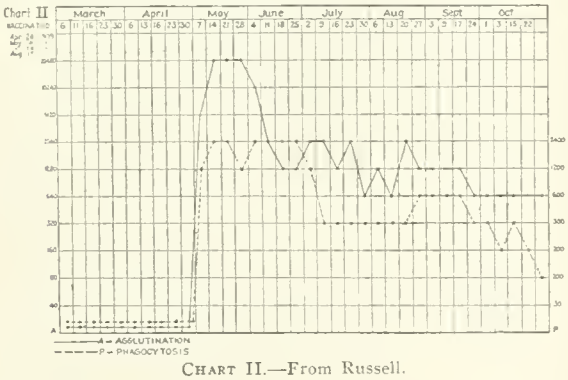

CHART II.—From Russell.

On May 7, however, there had been such a production of antibodies that agglutination occurred in a dilution of 1 to 5,120, and the opsonins were active in a dilution of 1 to 1,200. Seven days later, May 14th, twenty days after the initial inoculation and coincidently with the third inoculation, both reached the maximum, phagocytosis occurring in a dilution of 1 to 2,400, and agglutination in a dilution of 1 to 20,480. Thereafter both steadily declined.

Chart III[3] also is from a subject receiving the initial inoculation June 1, 1909. Four days later agglutination and phagocytic tests gave normal results. June 11 agglutination occurred in a dilution of 1 to 1,280 and phagocytosis in a dilution of 1 to 300. The maximum of phagocytosis was reached June 25 in a dilution of 1 to 4,800, and agglutination on July 2 in a dilution of 1 to 20,480.

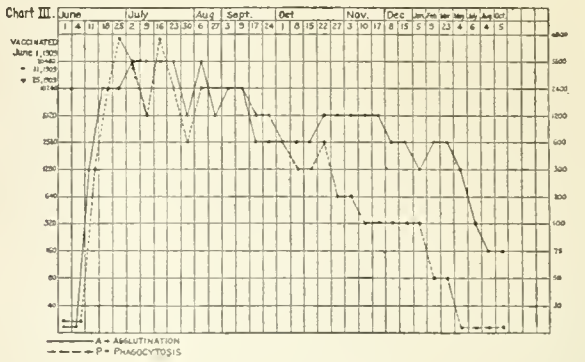

CHART III.—From Russell.

These charts, while varying in minor details, are uniform in that they show an incubation period between the inoculations and the beginning production of antibodies; that thereafter a rapid rise ensues, reaching a maximum twenty or twenty-five days after the first inoculation, and that subsequently there is a gradual decline to normal extending over a period of a year or more. I have quoted thus extensively from the work of Major Russell, because a full understanding of its significance is necessary in any discussion of the vaccine treatment of typhoid fever, and because any rational interpretation of results must fall within the lines laid down by his investigations.

As to the time of the formation of antibodies and their great increase, Leishman[4] agrees with Russell, although his work was done at an earlier period, when methods of measuring agglutinins and opsonins in typhoid fever were not so exact. He says: "The quantitative tests showed a various pronounced rise in the amount of the various protective substances, and this rise commenced about the eighth day after the first inoculation."

Clark and Simonds[5] made a study of typhoid opsonins on injection of rabbits, using the method of Wright. While they found the method unsatisfactory and recommend further investigation and study, their published charts show well the delay in the formation of large amounts of opsonins.

Corresponding to the time of development of antibodies in prophylactic vaccination, in the first eight or ten days of an attack of typhoid there is a constant increase of temperature and aggravation of all the symptoms. During this time, also, the typhoid bacillus may easily be demonstrated in the blood by cultural methods. By the eighth or tenth day the fever ceases to rise and remains on a level, rose spots appear, the bacillus is less constantly present in the blood, and the Widal reaction becomes positive in increasing dilutions. The fever remains constant for a varying period and then gradually declines to normal, with an increasing quantity of antibodies present in the blood, which may be demonstrated for long periods thereafter.

From this correspondence in time between the clinical symptoms and the antibodies in an attack of typhoid fever, and the development of antibodies and immunity in prophylactic vaccination, it seems only proper to assume that recovery from typhoid and the development of immunity in prophylactic vaccination are brought about by a similar mechanism, and that the latter, prophylactic vaccination, is

an artificial, controlled process which occurs naturally in an attack of typhoid fever.

The question has already suggested itself: Can this artificial, controlled procedure be applied in the treatment of typhoid, and if so, what results may be expected in the way of abating the symptoms of the disease and shortening the attack? As already shown, the development of antibodies in large quantities does not begin until between the fifth and tenth days, usually the eighth. Consequently, little can be expected during this period, unless it be some increase of the toxic condition of the patient, due to introduction of the vaccines. Beginning at the end of this period, the antibodies formed in the natural course of the disease plus those developed under the influence of the vaccine are present. If, as seems probable, the bacteria are overcome and the fever reduced by these antibodies, a more rapid fall of temperature and decline of symptoms should be expected.

Beginning at a period after the eighth day in prophylactic vaccination, the antibodies rapidly reach a high concentration, and, if the two processes are analogous, the antibodies in an attack treated by vaccine should have reached a concentration sufficient to overcome the bacteria present and cure the attack; for there is no reason to believe that the ability of the patient to react in antibody formation or to use those antibodies, once they have been formed, has been altered.

In order to learn to what extent theoretical considerations and clinical experience coincide, reports of cases treated are here introduced. Before discussing them, however, it may be well to call attention to the probable fact that in exposure to typhoid only a few bacteria are introduced and must be overcome; while in a developed case enormous numbers are present in the blood and tissues, and it is probable that a much greater concentration of antibodies is required for their destruction. The fact must also be considered that in the treatment of typhoid the curative action of the antibodies is exerted while newly formed and in high concentration; while in prophylactic immunity they must be active at later periods, when part of the antibodies developed at the time of inoculation have apparently disappeared from the circulation. The problem under consideration thus becomes most complicated, and the conclusions to be drawn must finally rest upon clinical verification.

The first systematic treatment of typhoid fever with vaccine was employed by Capt. A. B. Smallman[6] at Quetta, India, at the suggestion of Leishman. Leishman succeeded Wright as professor of pathology in the Royal Army Medical College at a time when the continuance of prophylactic vaccinations in the English Army was under discussion, and he was a member of the commission of the medical corps appointed to decide the question. A large amount of experimental work was carried out by this commission to determine the proper method of preparation and preservation of vaccines, the most effective dosage, and the time required for the development of antibodies and the amounts in which they are formed. One of Leishman's assistants in this investigation was Smallman, who, when this work was completed, took the field with an army unit with this vast store of information at his command. Thirty-six cases of enteric fever were treated with vaccines. The earlier cases received a dosage of 100,000,000, but this was soon increased to 300,000,000 to 350,000,000. The injections were given every third day. Three deaths and no relapses are reported for the series. Six charts are included in the report to show typical results. Of these Leishman says: "They are neither the best nor the worst evidences of the beneficial effect of the vaccine." These charts show normal temperatures on the ninth, sixteenth, fourteenth, sixteenth, thirteenth, and eleventh days. Of the results Smallman says: "As insisted by Chantemesse, they have 'an unexpectedly good appearance,' and it was no uncommon thing to go into the ward when full (*sic*) and find nearly every patient quietly and comfortably sleeping. The 'typhoid facies' was in most cases conspicuous by its absence . . . . There has been an unusual absence of prolonged cases, of complications, of sequelæ, and of relapses . . . Everyone who has been concerned in the care of these patients has been convinced that the injection of vaccine does produce undoubted good effects. Moreover, no bad results have so far been noted."

Kennedy[7] reports a severe case of typhoid fever, blood culture positive, with marked nervous symptoms, delirium, retention, and incontinence of urine. A stock vaccine was given, in doses of 50,000,000, on the eighth, tenth, fourteenth, and sixteenth days, with normal temperature on the twentieth day—twelve days after the first injection. Improvement was marked almost from the first injection.

Wilson[8] reports six cases of typhoid fever treated with vaccine in doses of 250,000,000 to 500,000,000, one to three injections being given, with no regular time between the successive inoculations. The temperature became normal on the tenth, second, tenth, seventh, eighth, and sixth days respectively after the first inoculation. There were no complications, relapses, or deaths, although some of the cases were severe, with marked nervous symptoms. He says: "In conclusion, the point that struck me most was the absolute difference in appearance of the cases of enteric fever treated with vaccine to other cases I have seen; they all looked so much fresher and more robust, with no anxious appearance, and all volunteered the information that they felt decidedly more comfortable after the injection."

Watters and Eaton[9] report a series of thirty cases, mostly mild, treated with typhoid vaccines in doses ranging from 15,000,000 to 60,000,000, mostly 25,000,000 and 30,000,000. From one to five inoculations were given. In the series there were two deaths; one was hopeless from the start, the other was moribund when treatment was begun. There were three relapses, and three cases appear not to have been markedly affected by the inoculations. In general, a normal temperature was reached between the eighth and the eighteenth day.

The same authors report[10] a later series of four cases treated with vaccine, each case receiving two doses of 30,000,000 and 45,000,000. Two cases came to normal rapidly without relapse. One came to normal rapidly, but suffered a short relapse. All did well. They quote from Dr. E. E. Allen, clinician in charge of the cases, who discusses them[11] as follows: "I will say, however, in the light of my experience, that were I now entering upon another three months' service, I would unhesitatingly give every case the benefit of the opsonic treatment at once, administering no other remedy until it was demonstrated that the case did not respond. . . . As I watched the progress of these cases I found myself relying more and more upon

the method. It was a very unique and interesting phenomenon to me to see repeatedly apparently serious cases of typhoid fever, presenting all the usual symptoms, rapidly overcome them and in a few days change the whole complexion of their illness for the better, going on to rapid convalescence. After but one treatment some of them began immediately to improve in every respect. The fever became less, the headache and backache disappeared, the tongue cleared up, and they began to complain of hunger. Most of them would say, if asked, that they felt better, and that, also, very soon after the initial treatment. About 75 per cent. of all the cases were favorably influenced."

Watters and Eaton[9] have recently reported a third series of 35 cases of typhoid fever in which vaccines were used with very satisfactory results. There were no deaths, two mild relapses and one hemorrhage. Some of the cases, such as I have classified as failures, were prolonged. Seventeen temperature charts are given, most of which can be interpreted in the light of Major Russell's work on antibody formation. The following facts are abstracted from one of their reports to the board of governors of the Massachusetts Homeopathic Hospital: "Thirty-six patients received vaccines and the results are compared with 71 not so treated. Average duration of fever: untreated, 25.3 days; treated, 15.5 days. Average residence in hospital: untreated, 57 days; treated, 39 days. Percentage of reinfections: untreated, 25; treated, 9.1. Average gain by those treated: In duration of fever, 9 days; in residence in hospital, 18 days; in relapses, 15.9 per cent. They still continue using the excessively small doses employed in their early cases, namely, the highest dosage 60,000,000; lowest, 2,000,000; average 25,000,000 to 30,000,000.

Wood[12] reports a case occurring in private practice. The case ran a course of two weeks from normal temperature to normal temperature, with delirium and a temperature of 104.5° between. Uninterrupted recovery followed. He feels that the disease was shortened.

Sappington[13] reports the results of twenty-two cases of typhoid treated with vaccines. The dosage was 5,000,000 to 50,000,000, given every day or every other day, the number of doses being from one to nine. There were three deaths in the twenty-two cases. The average duration of fever in the treated cases was twenty-four days—nineteen days after the first inoculation. The average duration of fever in a similar series not treated was thirty-one days. In giving his impressions he says: "In the twenty-two typhoids there was a distinct improvement in the symptomatology in about 75 per cent. of cases. This was usually quite obvious two or three days after beginning injections and progressive thereafter, and was sufficient in degree and rapidity of development to be foreign to the usual course of typhoid fever. The rapid improvement in several patients was most striking, as in one case of extreme stupor and in another with marked tympanites and manifestations of toxemia. In other instances the improvement was more gradual and not distinctly in evidence for six or eight days. In a few cases with nervous symptoms there was no betterment. One subject was apparently made worse. Two patients in whom the process was prolonged stated that they felt quite well, even during the febrile rise toward evening, and complained only of unsatisfied hunger. The early return of the appetite was an encouraging sign seen in many of the cases. Hemorrhage occurred in two cases, but was serious in neither. There was one case of perforation. There were two cases of recrudescence; none of true relapse."

Richardson[14] refers to a series of twenty-eight cases of typhoid treated with vaccines, twenty-five in the original attack and three during relapse. The dose varied from 10,000,000 to 100,000,000. The interval between doses averaged about three days. Sufficient facts are not given to analyze his results. He says: "The results of the treatment were not especially striking. As regards relapses, however, here again the effect of the treatment seemed to be favorable. In twenty-five cases inoculated there was, after inoculation, but a single relapse. This was very atypical and lasted but six days. Of seventy-seven untreated patients ten suffered typical relapses. I am, therefore, firmly convinced that whatever effect the vaccine may have on the original disease, there can be little doubt that the percentage of relapses can be much reduced by bacterial inoculation."

Semple[15] treated nine cases of typhoid with small doses of typhoid vaccine. The earlier cases received daily inoculations of 8,000,000, the later cases four daily inoculations of 30,000,000 each. No deaths occurred. He summarizes: "When appropriate doses are given the method is devoid of all risk, is easily carried out, produces no apparent disturbance in the patient's condition, and does not interfere with any other treatment the physician may deem necessary."

Hollis[16] treated eleven cases of typhoid with vaccine in doses ranging from 10,000,000 to 250,000,000. There were 30 per cent. of relapses in the treated cases, as against 10 per cent. in the untreated cases. There were no deaths in the vaccinated cases, as against four in twenty-one untreated cases. He seems to be very favorably impressed with the results, even in his smaller dosage. Headache, gastrointestinal symptoms, and toxemia were far less frequent in the vaccinated. Hollis reported an additional forty cases to the Medical Section of the Academy of Medicine on May 16, 1911. There were two deaths and five relapses. Both deaths were in acute, fulminant cases.

Ruffin[17] reports a case in which the fever had become chronic. He injected 800,000,000 typhoid vaccine, which caused a local and general reaction, followed by a satisfactory convalescence.

Martin,[18] in a series of cases treated with vaccines, includes two cases of typhoid. The first was put on vaccine treatment on the fifteenth day, received three doses of 50,000,000 each, with a normal temperature on the fifth day following the first inoculation. The second case was put on vaccine treatment on the fortieth day of the disease, when in an exhausted condition. Five doses of 30,000,000 each were given, death ensuing on the eighteenth day after the initial injection.

Anders[19] contributes a discouraging article on the subject of the vaccine treatment of typhoid fever. In it he reports a series of eight cases treated with doses of 25,000,000 and 50,000,000. Apparently, only a part of these cases came under his personal observation. Sufficient facts are not given to judge of the results, but one case suffered a relapse.

Nichols[20] reports eleven cases treated with typhoid vaccine. There was no plainly demonstrable effect, good or bad. There were no deaths, and the cases were of average severity. One had intestinal hemorrhage and relapse, one a relapse, and two were pro-

longed to thirty-three and thirty-one days. He says: "The results in the whole series are quite inconclusive. They probably show that typhoid vaccine, even in quite large doses, produces no harmful effect, but to what extent the favorable course in most of the cases was affected by the inoculations is indeterminate. Relapses certainly were not prevented."

Behrend[21] reports a series of cases (Russell[2] says twelve), and Ramsburg[21] and French[21] each one, with beneficial effects. In all, twenty-five cases were reported in this article and the discussion. On the whole, the results were not striking.

Duncan[22] treated six cases of typhoid with vaccine with very satisfactory results. The dosage ranged from 50,000,000 to 1,000,000,000, one or two injections being given with an interval of four days. He had no relapses, no deaths, no prolonged cases, and only one hemorrhage, with no other complications. He says: "In no case was the aggravation of symptoms sufficient to cause danger or fear of consequences. The aggravation consisted principally of pain in the joints, especially the arms, shoulders and legs, and a slight rise of temperature. The duration of the aggravation was from two to ten hours."

Illman and Duncan[23] treated one case without effect.

Fletcher[30] treated fourteen cases. The dosage was 500,000,000 and 1,000,000,000, one or two doses being given. In the series were one true relapse and two deaths, one from cerebral embolism and one from profuse hemorrhage. He concludes: "It may be said that the therapeutic administration of antityphoid vaccine is attended with no bad results and in no way increases the patient's discomfort. On the other hand, its use did, in all cases observed, improve the general condition of the patient, while in three cases its action was nothing short of marvelous. In view of these facts and granting the correctness of the hypothesis advanced above, it would seem that vaccine in typhoid fever is certainly rationally indicated."

Six cases of typhoid fever were treated with vaccine in the United States Naval Hospital at Mare Island.[31] There was one death from hemorrhage soon after admission to the hospital. The other cases were modified by the vaccines. Medical Director Simons says: "So far as my experience goes the vaccines do not cure many cases, but they certainly materially modify the severity of the disease. . . . There was absence of restlessness, thirst, lumbar pains, cephalalgia, and the patients were thus made very comfortable and the danger of hemorrhage lessened."

McLaughlin[32] has treated thirteen cases of typhoid with vaccines with no deaths. His earlier cases received a dosage of 25,000,000. Later this was increased to 50,000,000.

I have the following cases to report:*

Case I.—Master R. R.; white, age 15 years. He was sick ten days before admission. After one injection the vaccine was ordered stopped. This chart shows a condition which might well have been aborted—that of a continued low temperature. Twenty-five days from the first inoculation to normal temperature.

Case II.—Miss M. D.; colored, age 12 years. A mild case first treated on a relapse. Three days from the first inoculation to normal temperature.

Case III.—Miss M. E. B.; colored, age 38. For two weeks before admission she suffered from headache, anorexia, and fever. Complications were two hemorrhages. Eighteen days from first inoculation to normal temperature.

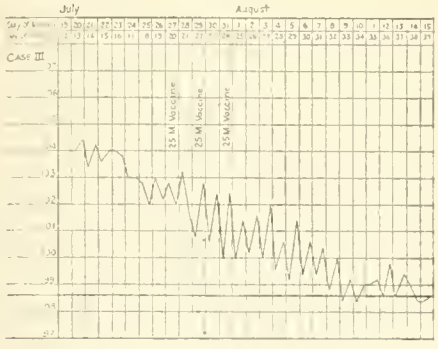

Chart IV.

Case IV.—Mr. H. B.; white, age 21 years. Patient was sick eight days before admission. He showed marked nervous symptoms—low muttering delirium, picking at the bed-clothes, etc.—with a high fever which did not respond to baths. Later in the course of his illness he developed numerous pustules and abscesses over the body. Many of these seemed to burrow deep into the tissues of the back and a culture showed the presence of streptococci. He was exceedingly septic from the absorption of toxic material from these. Ninety-one days from the first inoculation to normal temperature.

Case V.—Mr. A. J.; colored, age 21. He had been sick four or five days when admitted to the hospital. Twelve days from first inoculation to normal temperature.

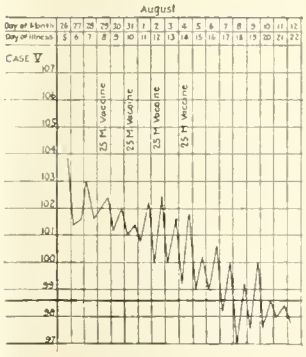

Chart V.

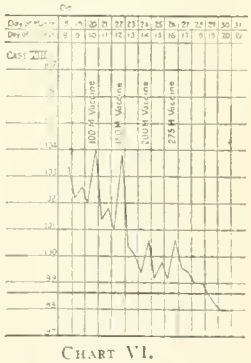

Chart VI.

Case VI.—Mr. A. B.; white, age 23. This was a case of typhoid preceded by pleurisy. He had been sick in bed for ten days and had been feeling badly for some time. On the day following admission a quart of straw-colored fluid was withdrawn from the right pleural cavity. Fifteen days from the first inoculation to normal temperature.

Case VII.—Master M. Y.; white, age 7 years. The patient was delirious, toxic and had a weak pulse when admitted. Ten days from the first inoculation to normal temperature.

Case VIII.—Mrs. A. W.; white, age 34 years. She had been sick about one week before entering the hospital. Ten days from the first inoculation to normal temperature.

Case IX.—Mrs. B. B.; white, age 37 years. Admitted December 14, 1909; discharged February 20, 1910. Days in hospital, sixty-eight. The patient was admitted early in the attack and gave a positive blood culture. She was a large, fleshy woman and was very toxic from the start. There

*The abbreviation M. in the charts indicates millions.

was no response to the vaccine treatment. Numerous hemorrhages complicated this case, and finally a femoral phlebitis set in. When discharged February 20 she was apparently about well, but very weak. The final entry on the chart is: "Discharged cured." The phlebitis, however, continued to extend, she failed to regain strength and, finally, died. A summary of the hospital cases would no doubt include this among the cured cases, but it is here entered among the fatalities. Sixty-one days from the first inoculation to normal temperature.

Case X.—Master R. F.; white, age 13 years. He had been feeling badly for nearly a month; would lie around the house, had no appetite, severe pain in the abdomen, slight cough but no expectoration. He was delirious on admission. Twelve days from the first inoculation to normal temperature.

Case XI.—Miss M. R.; colored, age 23 years. The patient was originally admitted to the gynecological department for pus tubes. About ten days before admission she had a severe headache and then began to vomit. Later she developed continu-

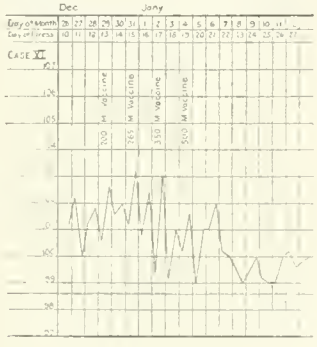

Chart VII.

ous sharp pain in the pelvis with backache. Twelve days after the first inoculation her temperature fell to 99° and continued between 99° and 100° as long as it was taken—up to within three or four days of her discharge. Eleven days from the first inoculation to normal temperature. History after discharge was not obtainable.

Case XII.—Mr. C. M.; colored, age 27 years. The patient was taken sick January 1, with pains in the legs, back, and chest and a general ill-feeling. About midnight of January 17 he had a severe hemorrhage, with others on the 18th and 19th. The patient was admitted with a bad sore throat which cultures showed to be streptococcal. He lay in bed most of the time with his mouth open, lips parched, tongue coated and cracked. January 18 lobar pneumonia set in. Died on the eighth day after first inoculation. No autopsy could be had.

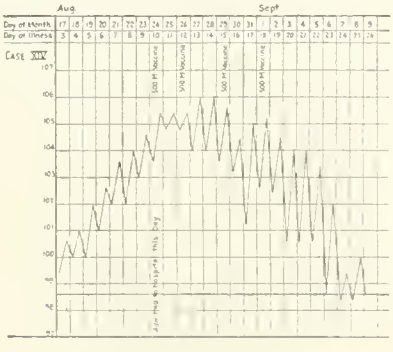

Chart VIII.

Case XIII.—Mr. H. E.; white, age 17 years. Patient was taken with grippe on Christmas Day, from which he did not entirely recover. This was followed by typhoid, and he was very delirious on admission and for several days thereafter. Temperature charts are missing from February 8 to February 22, and during this time he suffered a relapse. Twenty days from the first inoculation to normal temperature.

Case XIV.—Mr. L. P.; white, age 26 years. Ten days before admission he began to have headache, chilly sensations, and pains in the back. He took to bed four days before admission. During the early stages there was considerable vomiting, and the feces were passed involuntarily. The temperature before admission was taken by his wife, a former trained nurse. Fourteen days from the first inoculation to normal temperature.

Case XV.—Mr. L. B.; white, age 39. Two weeks before admission the patient began to feel badly, suffering from lassitude, loss of appetite, and severe frontal headache. Four days before entering the hospital he was compelled to go to bed. During the first few days in the hospital the patient suffered from uncontrollable headache, constant vomiting, and refused his food. This gradually wore off about the end of the first week in hospital. Fourteen days from the first inoculation to normal temperature.

Case XVI.—Miss K. A.; white, age 26 years. This case was first treated on a relapse on the twenty-second day in hospital or the thirty-third day of the disease. The relapse ran an uneventful course of about eighteen days after the first inoculation before the temperature became normal.

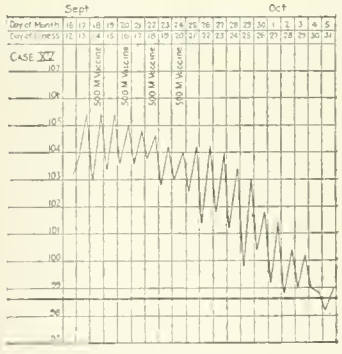

Chart IX.

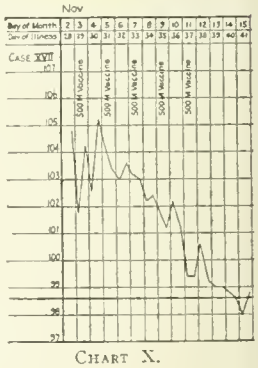

Chart X.

Case XVII.—Mrs. A. P.; white, age 32. The patient was a large fat woman with a baby five months old, which she nursed until about one week before entering the hospital. Four weeks before admission she began to have dizzy spells, with very marked lassitude, constipation, and later severe headache. One week later she took to bed, and one week before admission the eyes became red and inflamed and at the same time she became quite deaf. On admission the whole face was edematous and the eyes swollen, giving a fairly typical picture of oncoming uremia, with the following urinary findings: A heavy albumin ring with nitric acid; many hyaline, finely and coarsely granular, epithelial and rarely fatty casts; occasional blood cells and leucocytes. November 25, before discharge, the urinary report was as follows: Faint trace of albumin with nitric acid; occasional hyaline, granular, and epithelial casts; rare blood cells and leucocytes. Before her discharge, hearing had returned completely and the conjunctivitis of one eye had disappeared, the other improved. All edema had disappeared. Ten days from the first inoculation to normal temperature.

Case XVIII.—Mr. J. C.; white, age about 16 years. The patient was a Polish boy and no history was obtainable. Death was due to a meningococcus

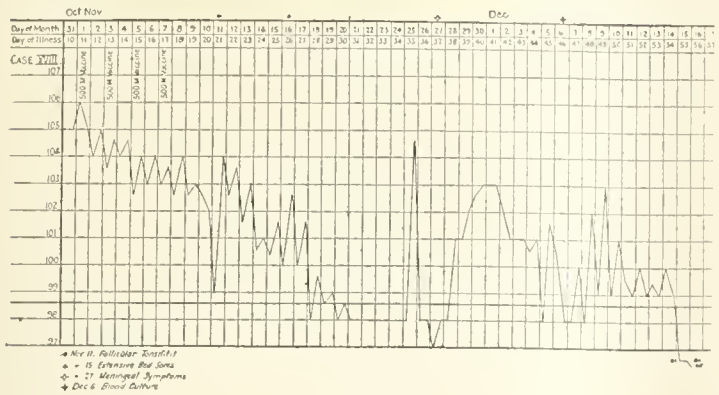

Chart XI.

septicemia. Seventeen days from the first inoculation to normal temperature.

Case XIX.—Mr. T. M.; white, age 35 years. The patient began to feel ill two weeks before admission

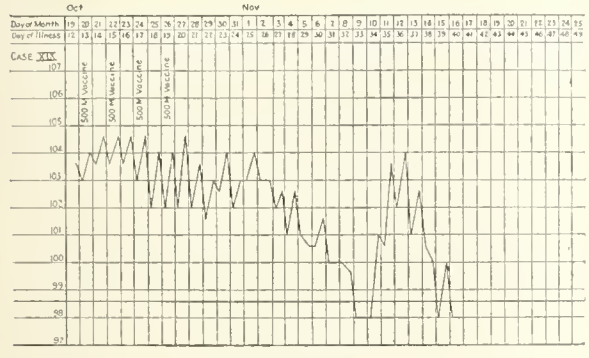

Chart XII.

and became progressively worse until he went to bed three days before entering the hospital. He was unconscious much of the first ten days in hospital, and several times at night was out of bed. Twenty days from the first inoculation to normal temperature. Recrudescence of fever lasting five days.

Case XX.—Mr. H. H.; white, age 21 years. The patient was sick about two weeks before admission to hospital. At the recrudescence of temperature on October 31 an abscess had developed on the anterior surface of the tibia and was opened. No bacteriological diagnosis of this was made. Four days from the first inoculation to normal temperature.

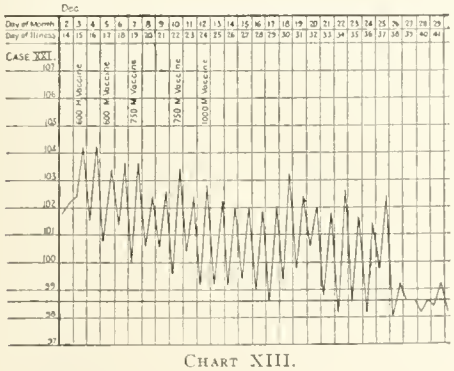

Chart XIII.

Case XXI.—Mr. S. D.; white, age 14 years. A severe case admitted about the fourteenth day of the attack. The chart suggests a possible paratyphoid infection. Twenty-three days from the first inoculation to normal temperature.

Case XXII.—Miss C. R.; white, age 21 years. Admitted to hospital about the eighth day of the disease. Nineteen days from the first inoculation to normal temperature.

Case XXIII.—Mrs. M. M. C.; an exceedingly severe case occurring in the private practice of Dr. Dennett. The case had been under observation about one week when the temperature chart begins. The patient was unconscious, with a low muttering delirium and other nervous manifestations. The case was pronounced quite hopeless when vaccine treatment was instituted. Sixty-five days from the first inoculation to normal temperature.

Case XXIV.—Mr. L. E., male, age 26. Attack began two weeks before admission to the hospital with a swollen ankle, followed by chilly sensation, weakness and general malaise. After one injection the vaccine treatment was ordered discontinued. Twelve days from the inoculation to normal temperature.

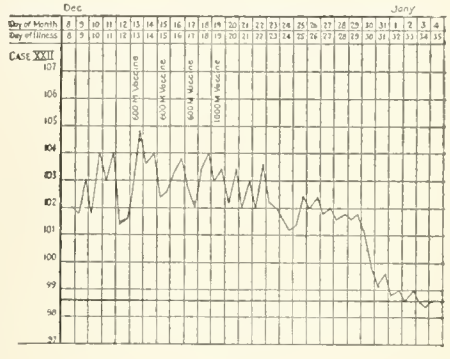

Chart XIV.

The combination of Chart XV., Case 22; Chart XVI., Case 15, and Chart XVII., Case 17, is self explanatory.

Cases 1 to 13 inclusive were treated in the wards of Mercy Hospital, at Baltimore, Md., in the service of Drs. Lockwood and Beck, and the vaccine treatment was given at the suggestion and under the direction of Dr. William Royal Stokes, bacteriologist of the Baltimore Board of Health. Cases 14, 15, 16, 17, and 24 were at the New York Post-Graduate Hospital; No. 14 a private patient of Dr. Augustus Caille, and the others in the service of Dr. Edward Quintard. Cases 18, 19, and 20 were at St. Francis Hospital, Jersey City, N. J. Cases 21 and 22 were treated in St. Elizabeth's Hospital,

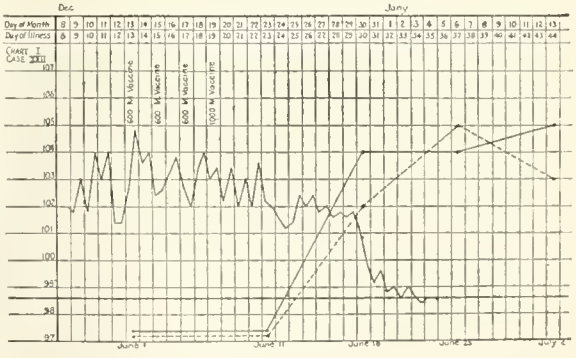

Chart XV.—The continuous line marks the agglutination, the broken line the phagocytosis.

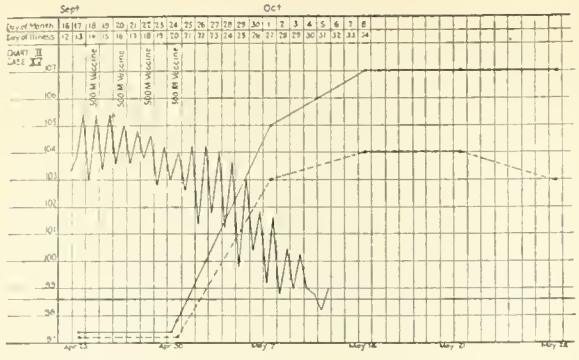

Chart XVI.—The continuous line marks the agglutination, the broken line the phagocytosis.

Elizabeth, N. J., in the service of Dr. Riley, the vaccines being given by Dr. Corbusier. Case 23 was in the private practice of Dr. Dennett, of New York.

TABLE OF COLLECTED CASES.

		Relapses.	Deaths.
Watters and Eaton	69	6	2
Hollis	51	8	–
Smallman	36	0	3
Richardson	28	1	0
Callison	24	1	3
Sappington	22	0	3
Fletcher	14	1	2
McLaughlin	13	0	0

Illman	1	0	0
Kennedy	1	0	0
Ramsburg	1	0	0
Ruffin	1	0	0
Wood	1	0	0
	323	20	17

In all, 24 cases have been treated. One case received one small dose and the injections were then discontinued. One was treated on what appeared to be a beginning relapse, but returned to normal so quickly that it is now doubtful whether it was a true relapse or only a slight recrudescence of fever. A third case (No. 20) showed a normal temperature so soon (the fourth day) after the vaccine treatment was instituted that it is doubtful if it was

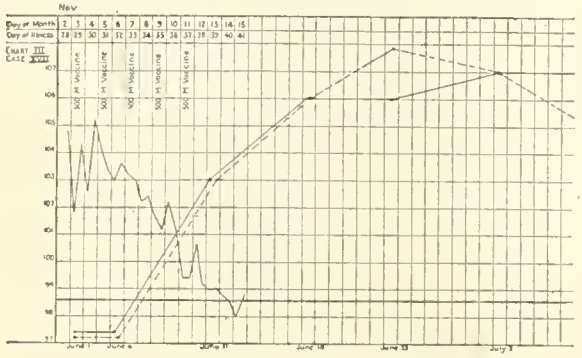

Chart XVII.—The continuous line marks the agglutination, the broken line the phagocytosis.

influenced by the vaccine treatment. After this case had remained normal for seven days the temperature abruptly rose from normal to 105° with the development of an abscess on the anterior surface of the tibia.

This leaves twenty-one cases from which conclusions may be drawn. In these twenty-one cases there was one true relapse and three deaths. By reference to the tables of antibody formation quoted from Russell it will be seen that the antibodies reach their maximum concentration about the twenty-fifth day. Three cases exceeded this period from institution of the vaccine treatment and may be discussed as prolonged cases or cases of failure.

The Failures.—The three failures were Cases 4, 9, and 23. Case 4 ran a febrile course of ninety-one days; case 9 ran a course of sixty-eight days and died after discharge from the hospital as the result of a femoral phlebitis developed in the course of the disease; Case 23 ran a febrile course of seventy-three days, ending in recovery. In all three cases the temperature chart changed from a typhoid to a septic curve, and the possibility of a secondary infection seems not remote. A later blood culture in these cases would have been interesting.

The Causes of Death.—Three deaths have occurred in the series—Cases 9, 12, and 18. As already stated, in Case 9 death occurred, after the patient had left the hospital as cured, from a femoral phlebitis and its sequelæ. In Case 12 death was due to lobar pneumonia, and in Case 18 death was due to meningococcus septicemia. No case of death from the usual causes occurred in this series of twenty-four cases, but all were due to the very rare causes of death.

Other Complications and General Conditions.—Hemorrhages occurred in three cases, in none severe enough to be dangerous. The series has been remarkably free from complications. It has been the almost universal testimony of those who came in contact with the cases that they seemed better for the treatment. They lost the "typhoid facies," seemed brighter, slept better, and appetite returned sooner than in cases not so treated.

Summary of Collected Cases.—I have been able to collect 323 cases that have been treated with vaccines in doses of various sizes. Among these 323 cases there were seventeen deaths, or 5.2 per cent., and twenty relapses, or 6.2 per cent. Among the deaths are two in the series reported by Watters and Eaton that were hopeless or dying when the vaccine treatment was instituted. Such cases should be charged to deaths under vaccine treatment only when all of a large series are receiving the treatment. Without these two deaths the 323 cases show a mortality of 4.6 per cent. The death rate in typhoid is variously stated by different authorities: Allbutt,[24] 17 per cent. for England; slightly less for continental Europe, 14 per cent. Osler,[25] 5 to 12 per cent. in private practice; 7 to 12 per cent. in hospital practice. Kelly,[26] gives the same figures as Osler. Smallman,[6] puts the death rate at 12 to 20 per cent. In six years in the Paris hospitals there were 960 deaths in 5,621 cases, or 17 per cent.

The Vaccine Used, Dosage, and Local Reaction.—Three vaccines have been used. The first thirteen cases were treated with a vaccine made from a mixture of seven recently isolated strains of typhoid bacilli. Then two cases were treated with an experimental vaccine furnished by a commercial

firm* and lastly the vaccine used by the United States Army for prophylactic vaccination, as prepared under the direction of Major Russell, was used in nine cases. In regard to the choice of vaccine, all the advantage must ever lie with the stock vaccine. It is ready to use as soon as a diagnosis is made; it can be used by the general practitioner, and lastly and most important, the typhoid culture from which it is prepared can be grown in the laboratory until it has lost all or the greater portion of its toxicity and can be then tested for antibody-forming qualities. This latter point cannot be insisted upon too strongly, as the literature contains many articles emphasizing the necessity of a highly virulent strain of bacteria in the preparation of a vaccine. There has been, so far, no demonstration of the formation of an antiendotoxin in typhoid fever, while there is ample proof of the formation of large quantities of bactericidal substances—opsonins and bacteriolysins—and it is upon these that reliance must be placed for recovery from typhoid fever. These antibodies depend for their formation upon the presence of the proteid radicle of the bacillary body and not in any sense upon the presence of the toxic radicle. The dose has ranged from three injections of 25,000,000 to five injections increasing from 600,000,000 to 1,000,000,000. In view of the time covered in this series and experience gained in other vaccine work, it may not be too presumptuous to recommend a dose to those trying the vaccine treatment for the first time. Give a first injection of 300,000,000 as soon as a diagnosis is made. The injections may be given every third or fourth day, increasing 100,000,000 each time, until 1,000,000,000 is given at a dose. No claim is made that this is the best dosage or spacing, but it will form a convenient working basis until a more definite determination has been made.

In the cases here reported, the inoculations were usually made into the subcutaneous connective tissue at the insertion of the deltoid muscle. Some were made over the tensor vaginæ femoris muscle on the thigh. Any location that is rich in connective tissue and not called into active motion may be selected. Following the inoculations there usually is some local reaction which sometimes is quite severe, but this subsides in from twenty-four to seventy-two hours. The patient's attention should be called to this, and he should be assured that it indicates simply the effective action of the vaccine.

The vaccine treatment was begun at various stages of the attack. In some cases the inoculations were commenced at an early date, while the temperature was still rising; in others they were begun during the fourth or fifth week. In these widely separated conditions there was no perceptible difference in the response to the vaccine treatment. This fact emphasizes the importance of early diagnosis and institution of vaccine treatment. The earliest possible diagnosis can be made by blood culture or bacteriological examination of the feces, and this should be done wherever a reliable laboratory is available.

Other Treatment.—A point deserving considerable emphasis is the other treatment to accompany vaccine therapy. If there is any rationale for vaccine treatment it is in the fact that it is an effort to follow or imitate nature's method of bringing about a cure. All other treatment is admittedly symptomatic. Routine it may be called, but it is routine only in the sense that long experience has proved that a certain routine most nearly meets the symptoms as they arise or prevents their development. If a vaccine will abbreviate the natural course of the febrile period, leaving it otherwise the same, then by all means the routine treatment should be continued until the vaccine controls the disease process. This has been the procedure in all these cases. The vaccine and routine treatment have been in different hands, and each has proceeded independently of the other.

The Value of the Treatment.—The almost universal testimony as to the value of vaccine treatment given by the long list of those who have used it, a testimony the more positive the longer the list of cases treated, must certainly carry weight. To attempt to form an unbiased judgment of its efficacy is, however, more difficult. This much may be said with assurance: I believe that it is as effective or more so than the cold baths or packs. Two things seem fairly certain: It does lessen complications and reduce the number of relapses. Grant these, and the argument for its use ceases. Any treatment that accomplishes these two things must shorten the average duration of cases and reduce the death rate.

The Rationale of Its Use.—This is the most difficult problem to deal with satisfactorily. Why give injections of vaccine to a patient who is suffering from both a localized and a blood infection? There is at present no entirely satisfactory answer to this question. Some suggestions, however, may be made as to the reason. The tissues at the site of the local infection are not the histological elements most active in the production of antibodies, and they are also partly devitalized by the local infection. Then, as Wright[27] says, it is a well known fact that in the production of antibodies subcutaneous inoculations are more efficient than intravenous. By subcutaneous inoculations the bacterial proteids are brought in great concentration into contact with those connective tissues which seem to be most active in the production of antibodies. As in the battle between cell and bacteria these proteids of *dead* bacteria are incapable of elaborating protective substances, all the tissue-cell energy under the stimulus of their presence is expended in producing antibodies. The blood infection may represent in a way the intravenous injection of a vaccine, while the vaccine treatment itself is a true subcutaneous inoculation of a vaccine. In this manner the patient receives the full benefit of both subcutaneous and intravenous inoculation. The vaccine treatment takes a process of nature which is running riot and accomplishing little, and converts it into an efficient, controlled process.

May the Vaccine Do Harm?—A question of vital importance is: May the vaccine treatment injure the patient? Almost every article on vaccine treatment emphasizes the danger of a vaccine given in excessive dosage, without making it clear as to what constitutes too large a dose. Too vigorous a treatment in any line certainly would be unwise, but my experience has led me to believe that the danger line is far removed from the rational dosage. Two of my cases in particular bear on this point. Mrs. A. P., Case 17, was exceedingly toxic from metabolic products which the kidneys failed to eliminate, as well as from typhoid toxins, and examination of the urine showed a most alarming condition of the kidneys; yet her improvement was most remarkable under vaccines pushed more vigorously than in any case up to that time. Mrs. M. M. C., Case 23,

*I wish to thank the department of experimental medicine of Parke Davis & Co. for vaccines furnished.

was making steady progress downward and her case was said to be hopeless. The vaccine treatment was pushed, yet without injury. Her condition was such that the least added burden would have proved fatal, and yet she progressed slowly to a cure.

The Negative Phase.—These treatment vaccinations seem to throw some light upon another question of great importance; that of the negative phase. There is a widespread belief that inoculation when there is liability to infection leads to a lowering of the resistance of an individual, a rise of temperature and an intensification of the clinical symptoms. This syndrome is referred to as the "negative phase." Both Leishman[4] and Russell[2] conclude that a "negative phase," if it exists in typhoid, is so slight as to be negligible. Some of the cases in this series, which were inoculated at a time when the condition was so grave as to be alarming, yet with no aggravation of the clinical symptoms, seem to confirm this conclusion. Certainly, if a patient suffering from the worst form of typhoid infection can receive a treatment inoculation with perfect impunity then there can be little danger in giving an uninfected individual a prophylactic inoculation in the "presence" of an exposure. In only a few of my inoculations was there a rise of temperature and in none was there a noteworthy aggravation of the clinical picture. The rise of temperature, when it did occur, seems rather to have been a coincidence except, perhaps, in one case (No. 17), where some rise followed most of the inoculations.

Relation to Prophylactic Vaccination.—A point that seems to be of some importance is the effect treatment inoculation may have upon prophylactic vaccination. This latter work, standing alone, must make slow progress because of the difficulties of interesting those whom it is desirable to reach. They must remain unfamiliar with the advantages of the step, and a long campaign of education will be necessary. Once begin the general treatment of typhoid fever with a vaccine and it at once will attract the attention of everyone exposed to typhoid. As the curative and preventive treatment are the same, there will be little difficulty in inducing those exposed to infection to take the treatment before they develop the disease.

The Work of Chantemesse.—Chantemesse[28] in Paris, between April, 1901, and July, 1907, treated 1,000 cases of typhoid fever with 4.9 per cent. mortality. During the same period in other Paris hospitals there were 5,621 cases of typhoid with 960 deaths, or 17 per cent. In addition, Brunon of Rouen treated 100 cases of typhoid with the same serum with three deaths, and Josias of Paris used the serum in 200 cases with eight deaths. The previous mortality in the practice of these two physicians had been 10 to 12 per cent.

This antityphoid serum is prepared by injecting horses over a period of several years with a highly virulent strain of typhoid bacillus. The serum is then drawn and is ready for use. The patient was given an injection of from five to eight minims, depending upon his condition. If there was no improvement at the end of ten days, a second smaller injection was given.

According to Chantemesse,[29] there follows an incubation period of from three to five days, after which the patient enters upon a period of rapid defervescence. In regard to the clinical condition of the patient, he has this to say: "Strangers visiting the wards are struck with the patients' appearance and remark that they resemble in no way the typhoid patients usually seen. The patients' general condition also is very quickly improved. Headaches disappear in a few hours, and as soon as the reaction period is over a general and perfectly evident feeling of comfort is experienced. Although the temperature continues to present oscillations for some time, the patients feel relieved, wish to eat, and pass much urine."

The resemblance of Chantemesse's results, both clinically and statistically, to those obtained by the vaccine treatment is so striking as at once to attract attention. Indeed, had I quoted from his description under reports of vaccine cases, no suspicion would have been aroused. The statistics are 4.6 per cent. of deaths in 1,300 cases as against 5.2 per cent. of deaths in 323 cases. Wright[27] concludes after a full consideration of the whole question, that Chantemesse's serum is a true bacterial vaccine. If this is true, as there certainly seems reason to believe, this large series of cases, extending over a long period of time, sets a mark to which those using vaccines in the treatment of typhoid may hope to attain—a goal to be striven for with all earnestness.

CONCLUSIONS.

1. The production of antibodies or protective substances in response to the inoculation of a vaccine follows definite fixed laws, regardless of whether the vaccine is given for proyphylactic or curative purposes, and the results in treatment must be interpreted in the light of what is known of these laws.

2. Inoculations of vaccine in typhoid fever prevent relapses and lessen complications, and in some cases probably also shorten the original attack.

3. Stock vaccines should be given in preference to autogenous vaccines in typhoid fever. The older the culture the better.

4. When given in therapeutic doses such stock vaccines are without injurious effect, and do not interfere with other treatment.

5. The routine treatment should be continued until the fever process is controlled by the vaccines.

6. The dosage used by many of those who have treated typhoid with vaccines in the past has been too small to secure the best possible results.

7. Every case of typhoid fever should receive vaccine treatment as soon as a diagnosis is made, and this should be continued until the temperature becomes normal or it is demonstrated that the case will not respond to this form of therapy.

My sincerest thanks are extended to all those men who have aided me in this work, especially to Dr. William Royal Stokes, of the Baltimore Board of Health, who insisted on my taking up this line of investigation and gave me many suggestions and much valuable assistance; and also to Dr. Henry T. Brooks, Professor of Pathology in the New York Post-Graduate Medical School, who has been my constant counselor, both in the further pursuit of the work and in the preparation of this paper.

SOME OBSERVATIONS ON THE ORGANIZATION OF HOSPITAL STAFFS.*

BY JOSEPH A. BLAKE, M.D.,

NEW YORK.

THE proposed affiliation between Columbia University and the Presbyterian Hospital has aroused more than the customary interest in the question of what is the best organization of the staff for a university hospital. The term "university hospital" is used because it is the most convenient one to designate a hospital in which the chief efforts of a university in teaching and research are to find expression.

The question is a broad one and a very important one, and it has seemed to me in our search for light upon it that there was no body of men to whom it could be more profitably put than this society, whose members are all actively engaged in hospital work, and most of whom are or have been teachers. This paper, although embodying my ideas, is practically suggestive and interrogative, and it is hoped that the discussion upon it will be full and critical. I do not propose to discuss any plan for the reorganization of the staff of the present Presbyterian Hospital in order to make it more adaptable for university needs, but shall speak only of a hospital which by location and construction is eminently fitted for educational and scientific work. Therefore, for the purposes of this discussion the hospital will be considered to be under the same roof or to be directly connected by corridors with the laboratories of the School of Medicine.

It is manifest that a university hospital should be a true general hospital, an allgemeine Krankenhaus, and contain all the specialties as well as medical and surgical divisions; but for our purpose the latter divisions alone are sufficient for consideration, for a system suitable for these two may be made with slight alteration to cover the others.

In discussing a plan of organization it is natural and proper to begin at the head or top and then work down through the various departments; and this plan will be followed in this paper.

Board of Managers.—Although perhaps some of the most efficient hospitals are administered by one man, who at the same time is business head and chief of the medical staff, yet in an institution of this size and scope it is not only wise but necessary to have a board of men versed in business and administrative matters to which the the business affairs of the hospital shall be entrusted.

They should not only have the responsibility of the realty and investments of the hospital, but should see that its expenditures are prudently made and that every dollar is spent in the most productive and efficient manner. They also dictate the policies of the hospital, and, being responsible for the proper conduct of the work of the hospital, should have the power of appointment and removal with certain restrictions, of its officers and employees.

Possessing such powers and responsibilities it is obvious that the managers should be selected with the greatest care.

In the first place the board should not be too large and unwieldy. While it may seem expedient at times to appoint men who may attract funds to the institution, this policy may be productive of harm in adding inactive members.

The managers should all be conversant with hospital management, and not only willing but in a position to be able to devote time and energy to its interests. This assertion does not necessitate that all should take an active part in the internal affairs of the hospital, for some, on account of their information and connections, may be of greater value in administering its investments and shaping its policies.

One of the objections to a large board which is most appreciated by the medical staff is the necessity of a campaign of education whenever an appointment is to be made or a change in medical administration contemplated. At these times one is often shocked by the ignorance displayed of the more essentially medical subjects. Under such conditions when the board is large and not wholly com-

*Paper read before the Practitioners' Society, April 7, 1911.

posed of men in touch with the hospital almost as much energy has to be expended as in educating the New York Legislature concerning vivisection. This electioneering in regard to appointments is one of the very objectionable features of present hospital management, which will be entirely done away with by the proposed system of nominations by the university.

It is generally conceded that the board of managers should not be more than fifteen in number, but it is essential that they should represent all the various interests which compose the whole.

Private philanthropy at the expense of a public institution is an insidious evil. This is sometimes overlooked by managers in appointing employees who would not be tolerated in a business institution. In this way a hospital can be filled up with employees whose work could be done by half the number. The fixed expenses of salaries, food, and lodging being the main ones, all these persons are evidently carried at a serious detriment to the efficiency of the plant.

The Hospital Staff.—The hospital staff comprises the physicians and surgeons in attendance upon the patients and also the men engaged in the scientific or laboratory work.

While it might seem better to consider the clinical and laboratory organizations separately, they are so closely connected as to make this undesirable and practically impossible. In fact, a closer association between the clinical and laboratory staffs than obtains in present hospital methods must be accomplished; for otherwise there would be little reason for bringing the great university laboratories into the hospital organization. The chief difficulty before us is how to bring this about in the most satisfactory manner.

In the first place, before considering this question it is well to review the actual status of the laboratory departments of a university.

Because of teaching and research these departments are developed to a higher plane and to a greater individuality than is necessary for the ordinary routine work of a hospital, and although it might seem best at first glance to organize for hospital purposes the laboratory departments of pathology, bacteriology, and chemistry under one chief or director, who at the same time should be the head of one of these departments, yet upon reflection it becomes evident that such an arrangement would create a department so large and unwieldy, and the chief would be so overwhelmed in administrative work, as to absolutely prevent proper attention to his own particular branch. The creation of a separate chief or administrative officer would be equally objectionable, since he would have no place or time for individual work. Each laboratory department must, therefore, preserve its individuality.

We may now return to the original question, namely: The best method for correlating the clinical and laboratory departments. It perhaps will be best to approach this question from the clinical side. It may be taken for granted that the only right way of conducting a clinical service is to organize it under a single head or chief, who may be called the *director;* under him these should be an officer with the title of *visiting,* who should be as nearly as possible his equal in experience and skill. If the service should comprise more than 150 beds there might be another *visiting;* next in rank there should be two or more *associate visitings,* and next several *assistant visitings.*

The assignment of duty to the members of such a staff will be taken up after we have considered what the work of the clinical division should be. Here at once arises the question as to where the work of the clinical division ends and the laboratory division's begins. If we delegate all the laboratory diagnostic methods to the laboratory divisions and the clinical work to the clinical divisions we shall reach a most unsatisfactory condition by educating and creating bodies of men who on the one hand know only laboratory and on the other hand only clinical methods. This situation obtains now in most of our hospitals, and is one of the greatest, if not the chief, obstacles to the development of well-rounded and equipped professional men.

The only solution is for each clinical division to be a complete unit and contain in itself the necessary staff and equipment to do all the ordinary laboratory diagnostic work. Investigations requiring complicated and special methods alone would be referred to the laboratory division. The laboratory division in such a plan is comparable to a reference library or a clearing house. This organization into complete divisions corresponds to the German plan of separate institutes, but it seems to me it would be best not to carry it to such an extreme isolation as is done in Germany.

In such an arrangement the duties of the medical division would comprise, in addition to the ordinary care and treatment of the patients, the morphological, bacteriological, and chemical examination of the body fluids and excreta; the development and application of physiological apparatus and methods, and, in short, any methods with which the modern practising physician should be familiar. The duties of the surgical division would be practically those outlined for the medical division, with the addition of a certain amount of tissue pathology.

The criticism of this assignment of duties will be at once the question: What is to become of the laboratory divisions? for, if you take from them the routine pathological, bacteriological, and chemical work and assign it to the clinical division, you are

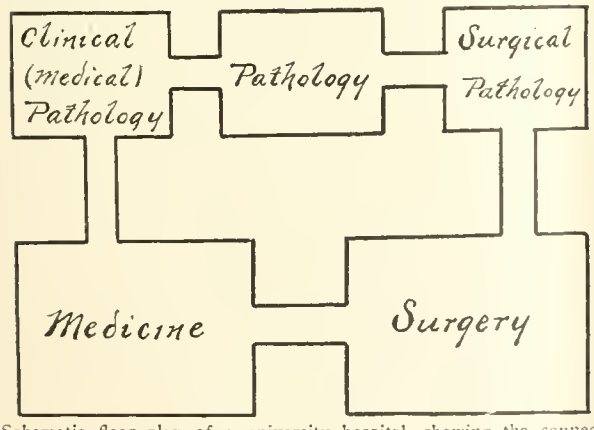
committing them to the dry rot of pure research, and defeating the aim of correlative and cooperative development you are trying to attain.

The answer to this criticism is *cross representation*, by which each division with the exception of medicine and surgery has representatives working in the other. The plan of organization may be likened to a complex molecule whose composite atoms are the different divisions, and the bonds of which are the cross representatives. The graphic formula of such a molecule in its simplest form would be

pathology being given the central and predominating position, and forming the link between bacteriology and chemistry. Medicine and surgery are connected with all three laboratory divisions. Changes in the valences can be made without altering the principle of the combination of the atoms. For instance, there might be two bonds, *i.e.* cross representations between surgery and pathology, or between medicine and chemistry. Other atoms can be added.

This construction of the molecule necessitates not only a personal but a physical connection between the divisions. To illustrate: Suppose two adjoining buildings connected by corridors, one housing the chemical, the other the laboratory divisions, the clinical building having two, the laboratory building three wings, a floor plan of such an arrangement being diagramatically as shown in the accompanying figure. In such a composite building the clinical divisions might occupy three floors; the laboratory divisions might each occupy one. Thus both medicine and surgery would be brought into close juxtaposition with each laboratory division.

So far the illustration has been simple and elementary, and it remains to be shown how the plan can be put into form for practical application. For this purpose it will suffice to take one clinical division and amplify its connections with the laboratory divisions. Because of my greater familiarity with the organization of a surgical division,



Schematic floor plan of a university hospital, showing the connection between the clinical departments and the pathological department.

and because in our surgical department at Columbia we already have in successful operation such connecting links, I shall use this division for illustration.

The principal subdivisions of a surgical division of a medical school and hospital, with exclusion of the space for didactic teaching, are three, namely, (1) wards and operating rooms; (2) laboratory for surgical pathology; (3) laboratory for experimental surgery.

The laboratory for surgical pathology has largely to do with tissue pathology, and must be in close connection with the main pathological division; it should also be connected with the bacteriological and chemical divisions.

The laboratory of experimental surgery should be in close connection with the laboratory of surgical pathology, and if possible with the department of physiology.

The clinical pathology, so called, of the surgical division is not so great in amount as in the medical division, yet requires space which should be in connection with the laboratory for surgical pathology.

The main bond between the surgical and the laboratory divisions is the laboratory of surgical pathology, which should be in charge of an appointee of the pathological division—a man, however, whose chief interests are directed toward surgical problems. It should be understood that this laboratory is for the use of the surgical staff and the pathological records of the surgical division should be kept there.

One of the *assistant visiting surgeons* is assigned to, and the major portion of his duties are in this laboratory. The clinical pathology of the division should be in immediate charge of the *overseers* of the *clinical clerks* (students).

This arrangement affords the *assistant visiting surgeons* and *overseers*, and the *resident surgeons* abundant opportunity for work, original or otherwise, in the laboratory departments.

The bacteriological work of the surgical and medical divisions is done by resident surgical and medical bacteriologists, who are members of the bacteriological division. Assistant visiting surgeons may be assigned to each of these divisions.

On the medical division similar connections may be developed, but probably more with the chemical division than in the case of the surgical division. Under such a general scheme the staffs of the divisions should be approximately as shown in the table.

With such an organization of the staff the assignment of staff duties would be about as follows: In the first place, the work of the hospital staff will be so closely correlated with that of the school and so many questions will arise in regard to educational and other interdivisional matters as to make it desirable to have a chief of staff, who should preside at the meetings of the medical board. If it should be decided that such an office was desirable, the natural incumbent would be the dean of the school. He should be the medium between the medical board and the managers, and if representation from the medical board upon the board of managers should be deemed advisable he should be the one selected.

The directors of divisions, and in their absence the first visitings, should be responsible for the administration of their divisions. Their recommendations should carry much weight in regard to the appointments of their staffs. They should have the assignment of duties of their staffs and entire direction of the teaching and research in their divisions, subject, of course, to the general rules and regulations of the hospital. The directors should have an office in their respective buildings, and, in the case of the directors of the clinical divisions, rooms for seeing patients in consultation. They should spend their entire working day at the hospital, and do no work outside of the hospital, with the possible ex-

ception of consultation work after certain hours, say 4 P. M.

The *associate visitings* in the clinical divisions should be men of skill and experience, and able to take entire charge of the divisions should occasion arise. Their work should be mainly the care of the patients.

The number of *assistant visitings* in the clinical divisions should not be fixed. Some of them should have fixed duties, namely, one as chief and another as assistant chief of the out-patient department, including the emergency department, for certain hours in the day; others should be appointed for certain special duties, such as in pathology, bacteriology, or research. The positions of these special assistants should be terminable at any time.

The duties of the *overseers of clinical clerks* have chiefly to do with teaching, but they should also have duties in the laboratories, mainly in clinical pathology.

The *residents* are in reality an advanced house staff. The duties of the house staff should be about as at present in our hospitals.

A *record clerk,* who should be a stenographer, is necessary for the care of the records of each clinical division. In addition, there should be clerks for the laboratory divisions, and a secretary for each director.

The *clinical clerks* are students assigned to laboratory and ward duty.

The Medical Board.—The medical board should consist of the *dean* or *chief of staff* as chairman, the *directors* and *first visitings* of the clinical divisions; the *directors* of the pathological, bacteriological, and chemical divisions, and the *superintendent* of the hospital.

The *first visitings* of the clinical divisions are added in order that their divisions shall always be represented.

The *superintendent* of the hospital, for obvious reasons, should be a valued member of the board, for through him the medical board can be kept in touch with the administrative problems of the hospital.

The medical board should be kept as small as is possible, consistent with proper representation of each division.

The Department of Nursing.—This department should be directed by the medical board, and the directress should report to the medical board or to the chief of staff. The *directress* should be appointed by the medical board.

The placing of the department of nursing in the charge of the medical board is contrary to the practice of most of our hospitals that are directed by a board of managers, but of necessity corresponds with that of hospitals directed by a single medical officer.

Nursing, if anything, is a form of treatment, and there is every reason why it should be controlled by those who have the responsibility of the care of the patients. Conversely, its direction by the managers who are not supposed to possess knowledge of medical treatment is equally unreasonable.

Other Departments Common to Two or More Divisions.—Under this category may be grouped the departments of radiography, hydrotherapy, mechanotherapy, etc. These departments should be under directors nominated or appointed by the medical board, and should report to the chief of staff. In this way direction by committees, with division of responsibility, will be avoided. The directors of these departments should not have seats on the medical board.

In conclusion, I may say that I am well aware that these remarks upon the organization of a university hospital are very incomplete, yet they may suggest ideas which, with further elaboration, may be of value in this most difficult and interesting question.

603 Madison Avenue.

THE ORGANIZATION OF THE UNIVERSITY HOSPITAL MEDICAL STAFF.*

By W. GILMAN THOMPSON, M.D.,

NEW YORK.

PROFESSOR OF MEDICINE, CORNELL UNIVERSITY MEDICAL COLLEGE IN NEW YORK CITY.

In discussing Dr. Blake's paper on the Organization of Hospital Staffs, I may say at the outset that I am especially interested, for what he has tabulated as an ideal scheme I have had in actual operation during the past year in the Cornell University Medical College Division of the medical service in Bellevue Hospital. Dr. Blake's hypothetical plan and the existing plan at Cornell are identical in practically all essentials, excepting that he recommends the employment of a permanent resident physician (or surgeon) with a resident assistant to him.

The accompanying table illustrates the assignment of the present Cornell staff.

ORGANIZATION OF CORNELL UNIVERSITY MEDICAL COLLEGE SERVICE IN BELLEVUE HOSPITAL (MEDICAL WARDS).

Hospital Appointees. 90 Beds.

1 Director (Professor of Medicine).
2 Visiting Physicians—
  a. Professor of Applied Pharmacology.
  b. Professor of Neurology.
2 Assistant Visiting Physicians—
  a. Professor of Therapeutics.
  b. Professor of Clinical Pathology.
4 Adjunct Assistant Visiting Physicians—
  a. Chief of Clinic O. P. D.
  b. Instructor in Clinical Pathology.
  c. Instructor in Clinical Pathology.
  d. Assigned to Pathology.
1 Resident Clinical Pathologist.
1 Visiting Ophthalmologist.
5 House Staff—
  a. Physician 2 years.
  b. Senior Physician 2 years.
  c. Junior Physician 2 years.
  d. Junior Physician 2 years.
  e. Physician 1 year.

University Appointees:

4 Laboratory Collaborators—
  a. Physiological Chemistry.
  b. Applied Pharmacology.
  c. Experimental Therapeutics.
  d. Medical Physics.

Clinical Clerks (sections of 10).
1 Clinical Pathologist for Clinical Clerks.
1 Trained Nurse to aid Clinical Clerks.
1 Trained Nurse to aid Metabolism Research.

It will be observed in this table that there are two groups of appointees, namely, those recognized by the hospital trustees as having definite authority in the wards, and second, those who come from the

*Read at a meeting of the Practitioners' Society, May 5, 1911.

university as guests in the hospital without authority to give any orders in the wards, but who serve as the personal assistants of the regular hospital staff and aid them in diagnosis and research. The members of the latter group being exclusive laboratory workers, having no means of support from medical practice, are salaried by the university, as are also those adjunct assistants who devote their time to instructing the clinical clerks. The essential features of the above plan, which distinguish it from the usual hospital service without university connection, are three, viz.: (1) Continuity of system throughout the year, without the usual interruptions of a rotating service; (2) the utilization of student clinical clerks for the benefit of the service, as well as for that of the students themselves; (3) the coordination of the university laboratories with clinical work.

It so happens that the visiting and assistant visiting physicians all occupy important university chairs. Thus the director, who is responsible for the general organization of the service throughout the year, is also the Professor of Medicine in the university. Another visiting physician is the Professor of Neurology, who, throughout the college year, visits all the neurological cases, which are set apart for him. Others are the Professors of Applied Pharmacology and of Therapeutics, who emphasize in their ward teaching their individual subjects. Another, an assistant visiting physician, is the Professor of Clinical Microscopy. In this manner many different points of view are brought to bear upon the service, and the patients have the benefit of the advice of special consultants whenever needed. The total general medical service comprises ninety beds, which are subdivided among the visiting staff so that each one has a definite number of cases for which he is directly responsible, and, in addition, he has leisure to confer with his colleagues regarding any other cases of exceptional interest. He also has leisure to conduct or direct special lines of research work with his own cases. The adjunct assistant visiting physicians are each assigned as assistant to one of his seniors on the staff, to relieve him of minor routine and aid in research, as directed.

An important member of the staff is the visiting ophthalmologist, who attends regularly once a week all the cases set aside for him, and comes at other times for emergency cases.

The ninety beds above referred to constitute the general medical service, but in addition, in rotation with other divisions of the hospital, the Cornell Division has charge in periodic rotation of the tuberculosis services and of the general medical cases arising in connection with the alcoholic and psychopathic services, amounting in all to 110 additional beds. One of the assistant physicians supervises this work, taking with him such of the junior members of the staff as he may need. The two latter services are under a permanent resident physician with resident assistants for the hospital at large, who are not assigned to any special division. This arrangement is the outcome of certain peculiar conditions of the service of this large metropolitan hospital, and are apart from any ideal plan of university organization. The clinical laboratory work of the wards which is not so elementary as to be done by the house staff, is performed by a resident interne in laboratories which adjoin the wards. This work comprises blood cultures, the making of sera and vaccines, and all the more elaborate clinical laboratory methods. Much accessory work of this sort is also conducted by the Professor of Clinical Microscopy and his assistants in the university laboratories.

In order to bring the out-patient service of the hospital into relationship with the wards, one of the adjunct assistant visiting physicians is made chief of clinic and responsible for the conduct of that service.

Practical continuity of service in the wards is secured by the director being held responsible for the organization throughout the year, by the visiting physicians being on continuous duty with all the various assistants throughout the college year. During the summer recess, when the service is light and there is no active teaching in progress, one of the visiting physicians is always on duty with a selected number of assistants, sufficient to maintain the character of the service.

In the practical working of this plan it has been found that upon an average at least six members of the visiting staff of the several grades visit the wards daily, for this service of ninety beds, no one of the chiefs having immediate charge of more than forty-five beds. What a contrast such a system affords to the former method by which a single visiting physician looked after the entire service alone, attended only by one or two members of an overworked house staff and a nurse or two, with his time and energy often wasted in matters of insignificant detail, and with little or no time and no facilities for research.

Thus the first requisite of a successful University Hospital, namely, continuity of organization and service, is provided for. The second condition is the provision for clinical clerks. During the past year we have admitted students in sections on consecutive afternoons only, but in the coming year they are to spend the entire day in the wards, each day for periods of ten weeks. The adjunct physicians instruct the clinical clerks, and a clinical pathologist is also assigned to them. In order not to interfere with the routine nursing work of the hospital, the university employs a nurse to aid the clinical clerks in the examination of patients. The system operates as follows: The clinical clerks go to the hospital early in the morning and collect and examine under the direction of the clinical pathologist the various specimens of blood, urine, sputum, etc., from the patients assigned to them, each student having five or six cases under observation at one time. He then devotes an hour or two to bringing his bedside notes of each case up to date and to taking new histories. In the afternoon he is directed in physical examinations by the adjunct physicians, and when in the course of his rounds the visiting physician reaches a case assigned to a student the latter is expected to present his work for criticism. The student also has opportunity to follow special operations or examinations in the wards and to see something of the research in special cases. His own work is constantly supervised and corrected, so that it is impossible for him to loiter. He thus studies simultaneously the subjects of physical and general diagnosis, therapeutics, and clinical microscopy. He is made to realize that his work is a part of the hospital system, and his histories, when corrected, become permanent records of the institution; hence he has every inducement to do good work. It is found practicable to give each student about eighty cases to follow during his ten weeks' clerkship. One of the adjunct physicians is to be

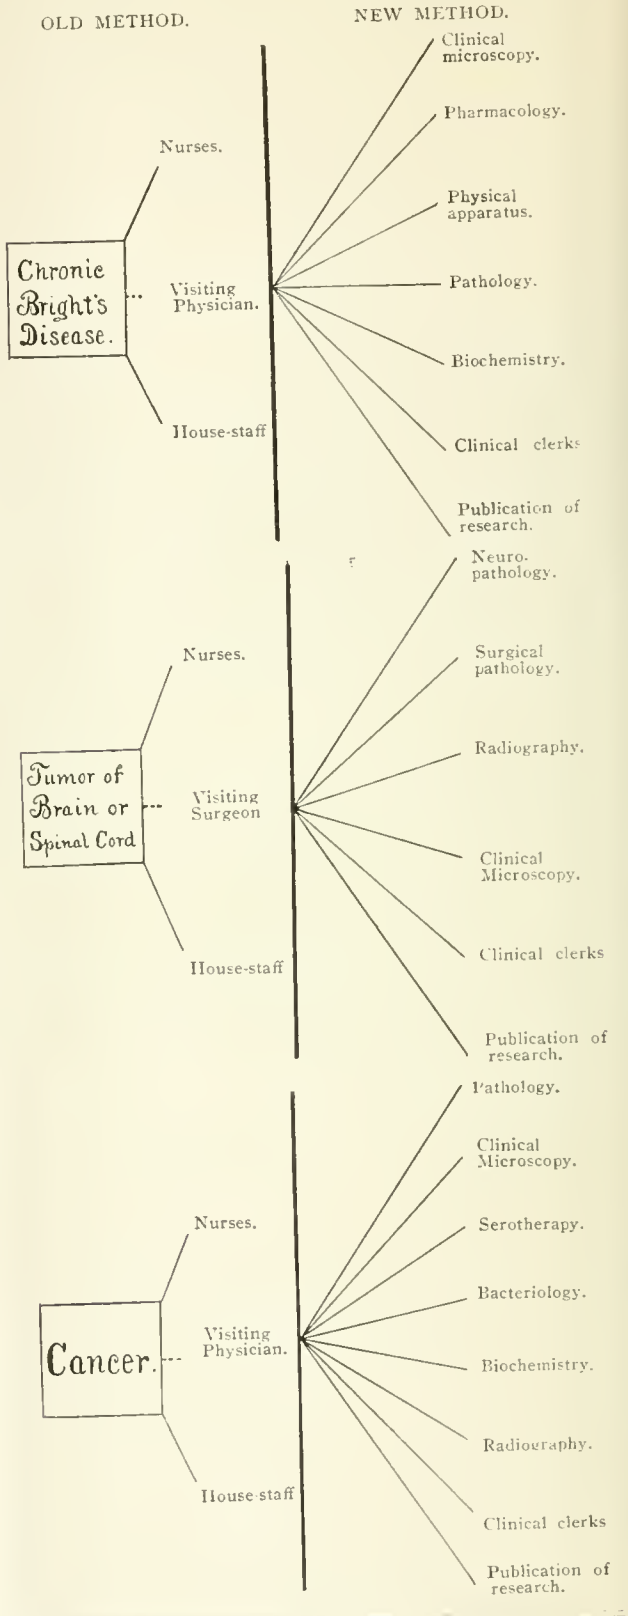
charged with the special duty of taking the clinical clerks from time to time to the museum of gross pathology in the college, in order to demonstrate specimens illustrating the probable lesions present in the patients whom the clinical clerk is studying.

It may seem unnecessary to thus describe in detail a system which in foreign university hospitals is as old as the institutions themselves, but its introduction in this country has been much hampered by the ignorance regarding its merits, not only among hospital trustees, but, I regret to admit, among members of the medical profession. The success of its introduction where it is a novelty depends upon two things; first, prevention of any idling or waste of time by the clerks, through their constant supervision by the salaried instructors; second, avoidance of any interference with the hospital ward routine. This latter difficulty is largely obviated by the extra nurse, salaried by the college, to prevent loss of time by the regular nursing staff in waiting on the students' cases. With these details provided for, the system has met with the unqualified endorsement of everyone concerned. On the part of the medical college the only difficulty exists in the withdrawal of the clinical clerks from all college exercises during their period of service, for if this service be constantly broken in upon, its value is almost wholly destroyed. It is, however, quite possible to readapt the routine curriculum to meet this condition, as soon as a medical faculty can be convinced that from the pedagogic point of view the student's period of clerkship is the most valuable part of his entire course.

The third distinguishing feature of the university hospital organization is the opportunity to develop close alliance between the various university laboratory departments and the ward work. The day is rapidly passing when a single visiting physician or surgeon can longer conduct a large hospital service with no other aids than his house staff. More and more he finds himself looking to the laboratory for aid. At first this was for diagnosis merely, but it is now to furnish means for treatment also, as in the case of the manifold sera and vaccines. For this latter reason especially, it is desirable that the laboratory worker should be admitted freely to the wards, that he may learn to estimate for himself the value of his work, and, by keeping in touch with the relative practical importance of the numerous and complicated laboratory procedures which ingenuity is constantly devising, he will be able to produce more satisfactory results in every way.

To bring about this cooperation we have assigned to each senior member of the visiting staff a laboratory worker, whose function is to act as mediary between ward and laboratory. Thus one of the visiting staff, being especially interested in metabolism, assigns certain cases to his laboratory aid, who takes specimens for analysis to the physiological or biochemical laboratory. Or at another time, desiring to study accurately the effect of certain drugs, the laboratory aid is assigned to do polygraph work, make animal experiments, etc. Another visiting physician may be especially interested in a new application of physical apparatus to the study of the mechanism of the heart action. He has as his laboratory aid an expert in physics, who works both in ward and laboratory. At present we are thus employing laboratory aids attached respectively to the university laboratories of physiology and physiological chemistry, pharmacology, experimental therapeutics, serum therapy, physics.

What the hospital may gain from the university (showing the dependence of the ward service upon the cooperation of the laboratories to study problems of bacteriology, food, drug purity, etc.):



Besides, there is a salaried nurse to follow metabolism cases. I have also instituted a series of weekly ward rounds which all the university laboratory workers are invited to attend together, for the purpose of discussing important cases.

By this system of organization I feel that we

have done much toward overcoming the difficulties pointed out by Dr. Blake of securing a proper balance between ward and laboratory, by the simple expedient of regarding the *ward as a laboratory*.

The university hospital is unquestionably the hospital of the future of this country, as it is of the past and present in all European countries. According to the Report on Medical Education of the Carnegie Foundation, a close alliance has already been formed in some fifteen instances by university medical schools and adjacent hospitals in this country and Canada. Such alliance, or better, such mutual control, is bound to be extended as it becomes better understood. What we greatly need in this country is a training school for hospital trustees, where laymen may be made to realize before graduation that a well-organized and progressive modern hospital is no longer a mere boarding house for the sick, but a great scientific and educational institution where the patients, while serving good purpose for both education and research, are at the same time securing for themselves, gratuitously, a degree of interest in their maladies, and of expertness in their treatment, obtainable in no such degree elsewhere.

As a basis for the course on proper laboratory equipment in such a school I submit the above diagrams to illustrate for lay trustees how necessary it is for the clinician in the ward to be able to prop himself up with adequate laboratory supports.

A CASE OF ADDISON'S DISEASE.

By LEONARD WEBER, M.D.,

NEW YORK.

Addison's disease is of sufficiently rare occurrence to make the publication of every new case desirable.

Mrs. E., German, medium-sized brunette, married, the mother of three apparently healthy boys, stated that she was always well before her marriage and fully able to do the usual housework. She admits the occurrence of a case or two of pulmonary tuberculosis in her family, but has never had any lung trouble herself nor any inclination to colds or coughs. When the first consulted me ten years ago she complained of slight but persistent headache and presented a number of small efflorescences on the inner side of several fingers of both hands; they were quite round and slightly desquamating, as they are often seen in latent syphilis. Her husband did not deny having had a venereal sore about five years before marrying, followed by uncertain secondary symptoms; he had perfunctory treatment only and the appearance of symptoms of locomotor ataxia occurred about seven years after infection, not accompanied by fulgurating pains and remaining stationary up to the present time. The patient was ordered mercury and potassium iodide for two months, when all specific symptoms had disappeared. However, during every spring of the next three years she had a recurrence of the same symptoms; the same treatment was used with equally good results.

Another relapse showing up in the spring of 1908, the patient was put through a course of intramuscular injections of 15 minims each of a 10 per cent. emulsion of salicylate of mercury in albolene, of which she received one every week until ten had been given. After that she remained free from all specific symptoms, spent some months in Europe in the summer of 1910, and returned in September. Being sent for to see her early in October, I heard that soon after coming home she began to feel tired and weak and had lately lost her usual appetite. It was a surprise to me, indeed, to find the triad of Addison's disease—pigmentation, weak pulse, and gastric disturbance—well marked and the general adynamic state of the patient rather alarming. The pigmentation of the hands, forearms, face, and neck was grayish brown; that of the nates and groin almost black. Of suprarenal extract tablets she began to take one three times a day, after meals; the second week, four; the third, five; and the fourth, six a day. By that time I could observe a clearing up of face, neck, and hands, there was a better pulse, appetite had returned, vomiting occurred but seldom, and nausea, previously annoying, had disappeared. The patient's spirits had risen; she could be allowed to leave the bed and spend some time on the lounge and have her somewhat noisy boys around her for a short while. The improvement, however, did not hold; in spite of the continuation of the suprarenal tablets, strychine, and stimulants, the pulse became smaller and smaller and the sense of weakness and exhaustion increased. Again there occurred respite and improvement for about three weeks, but, from January 15 on, discoloration of the skin advanced again, the pulse rose to 96 and more, became very feeble, and the appetite was poor. In the night of February 12 the heart began to fail, coma set in, and death occurred on February 13.

About six years ago Dr. F. Schwyzer demonstrated before the German Medical Society of this city a few specimens of degenerated adrenals taken from cases of Addison's disease, and stated it as his opinion that the destructive process in them was of syphilitic origin—gummatous. No autopsy having been permitted in my case, it is impossible to say whether the adrenals of Mrs. E. had been destroyed by lues or tuberculosis. The fact that she had not presented any further specific symptoms after the last and thorough series of mercurial injections, felt quite well while abroad, and did not yet complain on her return on September 10 would not exclude luetic degeneration of the adrenals; the unusually rapid course of the disease—six months—also points more in that direction, but it may have been tuberculosis, nevertheless. The patient's adynamic condition, well marked at the beginning of clinical manifestations, became rapidly progressive, the loss of muscular tone and force of the cardiac organ soon led to a blood circulation so feeble that it was often difficult to detect a pulse wave. The pulse, generally above 90, would frequently go beyond 100; there was no elevation of temperature, but occasional subnormal temperatures were noted in the course of the disease. Recollecting some rather favorable reports I had read of the efficacious use of animal suprarenal substance in Addison's disease, I was prepared to hope for continuation of improvement as apparent after four weeks' treatment, and felt quite disappointed when the patient ceased to respond to the remedy. Compared to the results we get from thyroid extract in myxedema, those obtained from suprarenal in Addison's disease have been meager. Strychnine in gr. 1/30 to 1/20 doses three times a day is required in every case, and so is a mixture of muriatic acid and pepsin several times a day, without which my patient could neither eat nor digest. Iron and arsenic are not well tolerated.

132 West Seventy-third Street.

PENNSYLVANIA'S WORK IN RURAL SANITATION.

By HARVEY B. BASHORE, M.D.
WEST FAIRVIEW, PA.

Only a few years ago rural sanitary conditions in Pennsylvania were very primitive indeed; people drank any water they wished, scattered pollution everywhere and anywhere, treated contagious diseases as a joke, thanked the Lord for his beneficent care, and gave the State Board of Health a meagre $6,000 a year. Meanwhile the cities, more progressive, were trying to preserve the health of their citizens while fresh foci of disease lay immediately outside their borders, unguarded by a restraining hand. But the "cloud with the silver lining" appeared in 1905 in the creation of a new Department of Health, with very ample means and ample laws, and the appointment of Dr. Samuel G. Dixon as Commissioner.

In the reorganization of the sanitary forces of the State, special attention was paid to the rural districts, so that we can now make the boast, and justly, too, that the rural districts of Pennsylvania get better sanitary supervision, being directly under the State authorities, than most of its large cities. Each county is under the charge of a medical man, assisted by a number of township health officers, who are, in fact, sanitary policemen. All contagious diseases are reported by the attending physicians to these health officers, who in turn placard the premises, disinfect at the proper time, and attend to the other numerous details incident to public health work. The county inspector is held responsible for the sanitary conditions of his county, and is given a very free hand, untrammeled by red tape, especially in times of an approaching epidemic. For efficiency and organization I do not believe the department is equaled by any in the whole country. These rural health officers have a pride in their work and a spirit of loyalty to the department that cannot fail to make their work a success. I once had a health officer who, during a smallpox epidemic, worked until midnight and then started off at three o'clock the next morning to run down a "contact" out in the mountains, and he did his work effectually and stayed an epidemic. Men do not work that way for money alone.

In dealing with contagious diseases modified quarantine is used whenever possible; that is, the patient is completely isolated and the wage earner of the family is permitted to attend to his usual work under certain restrictions; and it may be affirmed that this method, in spite of the adverse comment of many physicians, does work well in many localities. In one instance (I do not suppose there are many like it) I saw a quarantined farmer descend from his second-story window on a ladder rather than go through the sick room containing scarlet fever; and this was not done for my benefit, as the man was unaware of my presence. Now and then we meet a family unable or unwilling to abide by the requirements of this plan, and we then enforce absolute quarantine with guards, although such is rarely necessary. At first there was much misunderstanding about this modified quarantine, and it took lots of talk and explanation until the public got to appreciate its value.

Nuisances which used to be tolerated in the cities are now no longer permitted in the country; leaking privies, filthy hog pens, and barnyards are considered just causes for interference even if in the farthest backwoods. Public water supplies are especially guarded by the removal of all apparent sources of pollution, and any case of typhoid fever occurring on the watershed of such a stream calls for the immediate personal attention of the medical inspector of the district.

All dairies, that is all farms, large or small, from which milk is sold, are inspected twice a year by the local health officers, the conditions noted and forwarded to the department for action. At the same time printed circulars on model dairy work are given each farmer. In my own county, where there are at least a thousand dairies, the health officers inform me that with almost no exception the work is well received by the farmers, and that there is a marked improvement in sanitary conditions since the work began several years ago. The appearance of a case of typhoid fever, smallpox, diphtheria, or scarlet fever on a dairy farm anywhere in Pennsylvania calls for very drastic measures. The county medical man immediately visits the place and unless all the regulations of the department are enforced the sale of milk is prohibited.

The department is now about to undertake another new work in the medical inspection of all the rural schools, a procedure never before attempted. I do not mean daily inspection such as is in vogue in the cities, that would be impossible, but inspection about twice a year by certain local physicians appointed for that purpose. This plan was tried as an experiment recently in the three counties of Cumberland, Dauphin, and Lancaster, and yielded some striking results in the number of defective pupils. We used to think that country schools had all healthy children, but this experimental work showed that at least 21 per cent., almost one-fourth of the entire number, had some defect, mostly of vision or hearing, a condition which surely calls for some thought from the public educators.

Still another function of the department, which probably saves more lives directly than all the rest of the work put together, is the free distribution of diphtheria antitoxin to the poor, in the country, as in the city. Two nights ago I was driven twelve miles from a railroad station to see a family, the mother and five children of which lay sick with this dread disease: poor, very poor they were, but the State gave the helping hand in the shape of forty dollars' worth of antitoxin and saved at least two lives. Is it any wonder that the farmers of Pennsylvania laud Dr. Dixon and the State Department of Health? The tuberculosis crusade which is now going on with great activity in Pennsylvania touches the rural districts through the local dispensaries which are situated in every county: their visiting nurses spread the gospel of fresh air from farm to farm, to the lonely mountain dweller as well as to the inmate of the crowded tenements. Although at first this health work, of necessity, had to be mainly educational, not only of the public, but of the physicians, for many of them viewed with distrust the sweeping innovations of the new Department, it is already beginning to show fruit in a lessened sick rate and a lessened death rate: but this is only the beginning; the end, if there is any end, means longer lives, much less sickness, more human efficiency, more wealth, temporal good, and happiness. Already we see the beginning of the golden day.

MEDICAL RECORD.

New York, June 24, 1911.

INFECTIOUS ICTERUS OR "WEIL'S DISEASE."

WHEN in 1886 Weil called attention to a clinical entity of infectious nature, and characterized by the presence of fever, jaundice, enlargement of the spleen, and nephritis, he really described what had for a number of years been recognized by other observers, although it had not been so carefully studied. The "icterus" of Eudes, the "biliary or hepatic fever" of Landouzy, the "catarrhal icterus" of Chauffard, the "hepatic typhoid" of Mathieu were all identical with the condition described later by Weil under the name of "typhus biliosus nostras." Within recent years this condition has been widely recognized by clinicians under the name of "infectious icterus," or "Weil's disease," and many contributions have been made to the literature regarding it. The latest of these is the report of clinical and etiological studies of the disease as it presented itself during an epidemic at the military garrison of Hildesheim during the summer of 1910. This epidemic comprised a series of twenty cases which were carefully studied by Dr. Hecker, general surgeon to the Tenth Army Corps in Hanover, and Staff Surgeon Professor Dr. Otto, chief of the bacteriological division of the same army corps. Their interesting conclusions as to the clinical features and nature of this disease are presented in a monograph* published under the auspices of the medical division of the Prussian Ministry of War.

The clinical manifestations of this epidemic were the sudden onset in hitherto healthy and robust soldiers of dizziness, pain in the head, back of neck, and loins; nausea; high fever; relatively slow pulse; and pronounced prostration. In several of the cases, in addition to these symptoms, there was from the outset vomiting of bile, and in almost all of the cases there were distinct albuminuria and constipation, preceded as a rule by diarrhea. The temperature ran a course that was distinguished by no particular type. In most of the cases there was a distinct enlargement of the liver, while enlargement of the spleen could not always be demonstrated. Examination of the secretion of the throat, and of the stools, urine, and blood, with the aid of careful cultural and serological methods, enabled the army surgeons to rule out influenza, typhoid fever, meat poisoning, and malaria. In two of the cases the onset of marked jaundice, together with epistaxis, hematuria, and cardiac weakness, suggested that all of these cases were probably instances of Weil's disease. This was confirmed by subsequent observation. Only in a few of the cases, and only at the height of the epidemic, were all of the characteristic symptoms of the syndrome present. Of the subjective symptoms headache was the most prominent. The muscular pains were of extraordinary severity. In all of the cases there was a distinct swelling of the mucous membrane of the pharynx, and in eight of the cases there was an accompanying bronchitis. The nausea and vomiting which were present in 45 per cent. of the cases were parallel with the severity of the irritation of the kidneys. In all of the cases except one there was evidence of the latter in the albuminuria which continued as long as the fever lasted, and in six cases persisted for several weeks. Herpes was observed in one case, and in seven instances there was a papular eruption on the chest and abdomen. Petechiæ were observed in one case. In three of the cases there was hematuria, and one patient gave evidence of severe uremia lasting a whole week. In the patients who were not jaundiced and who had slight renal involvement the height of the disease was reached on the fourth day. In one-half of the cases the liver was distinctly enlarged and tender, and in one-third of the cases the spleen was palpable but not tender. Jaundice was present in 30 per cent. of the cases, and was of various degrees of intensity. The course of the temperature and its duration differed in the various cases. The patients were discharged from the hospital in from 36 to 77 days.

One interesting and possibly significant circumstance was noted in the above epidemic. All of the victims were swimmers, and had frequented the regimental swimming pool. The outbreak of the epidemic was coincident with the opening of the latter, and its subsistence corresponded with the close of the swimming season. The epidemic was confined to the months of July and August. It was noted that those who had practised most arduously in the swimming pool developed the most pronounced types of the infection.

Investigations into the etiology of the disease were undertaken without revealing any definite cause. The association with the swimming pool suggested a water-borne infection. Cultural and inoculation experiments were made, but no organism was isolated. Three monkeys were inoculated with blood taken from patients suffering from this disease, but in only one of the animals thus treated did the symptoms of the condition develop.

Hecker and Otto conclude from their most interesting study that Weil's disease is a non-contagious acute infection occurring almost exclusively in the summer months. It runs a characteristic course with symptoms that strikingly vary in the different epidemics. The typical and mild cases are seen at the beginning and end of epidemics. It is assumed

*"Beiträge zur Lehre von der sogenannte Weil'schen Krankheit," von Generalarzt Dr. Hecker und Stabarzt Professor Dr. Otto. Berlin: August Hirschwald, 1911.

that the unknown pathogenic cause is of local distribution, is no culturable organism, develops outside of the body, and in all probability is transmitted by some insect.

THE STANDARDIZING OF DISINFECTANTS.

There are many among modern health authorities who conceive that disinfection after a communicable disease has been present is a futile measure. They base their belief upon the hypothesis that when a patient who has been suffering from an infectious malady is dead or has recovered the pathogenic organisms which caused the disease speedily die after leaving the body. Charles V. Chapin, superintendent of Health, Providence, R. I., is a disbeliever in disinfection for the reason that he considers it superfluous in the light of the theory that disease-producing bacteria begin to lose their virulence and die almost as soon as cast off. Chapin delivered an address to this effect before the American Public Health Association in September last. A writer in the Bulletin of the Illinois State Board of Health, February, 1911, takes Chapin severely to task for the iconoclastic opinions expressed in the address, and ends an indictment of the theory that disease germs die soon after leaving the body with the following paragraph: "Health officers who are charged with the safeguarding of the lives and health of the people should give no heed to the *laissez faire* policy advocated by Dr. Chapin. The law will not tolerate such experiments. It demands the exercise of all possible care. In all cases of doubt the safest course should be pursued, remembering that it is infinitely better to do too much than to run the risk of doing too little."

But there is another point in connection with disinfection which is deserving of the most serious consideration and that is the germicidal power of disinfectants. If it be granted that disinfection after infection is a procedure necessary to the prevention of the spread of disease, it is obvious that the disinfectant used should be capable of destroying the germs. It is not enough that a substance should be a deodorizer and an antiseptic, it is essential that it should possess the power of destroying the specific poisons of a disease. If it will not do this then it is worse than useless. Standardization of disinfectants, to some extent, was brought into vogue in several European countries a few years ago. Professor Hewlett of King's College, London, the Milroy lecturer for 1909, devoted his lectures to a consideration of disinfectants, discussed standardization, and reviewed the various methods employed to test disinfectants. Koch was the first to introduce a method for standardizing disinfectants in Germany in 1881. His method is known as the "thread." Koenig and Paul introduced the "garnet" method in 1897. The thread method is, however, too elaborate in its technique and the garnet is generally characterized as untrustworthy. In 1903 Rideul and Walker brought out the method termed the "drop." By this method the disinfectant to be tested is compared with carbolic acid, and the solution of each which is germicidal in the same time on a standard organism, is ascertained. The dilution of the disinfectant divided by the dilution of carbolic acid, each of which accomplishes the same work in the same time, is termed the carbolic acid coefficient. The standard organism usually employed is the typhoid bacillus. The drop method is simple in technique, and by its employment it can be determined whether or not a disinfectant is kept up to the standard. In short, its use is more or less a security to the public that commercial disinfectants have sufficient germicidal properties. Hewlett stated in the Milroy lectures that the drop method, since its introduction, has done more for raising the standard of disinfectants than anything else, and by its use in Great Britain and in parts of Europe a number of inefficient disinfectants have been shown up and to some extent eliminated. The drop method has been officially adopted by the British Admiralty and Army Departments and by a large number of sanitary bodies in Europe and in Great Britain. The method, however, is by no means ideal, it is deficient in that no organic matter has been introduced into the test and other methods have been devised to overcome this difficulty, and have been tested at the Lister Institute. None has met with success enough to make it of much value in practice.

THE DIAGNOSIS OF DISEASES OF THE LIVER.

An important series of investigations on this subject have been carried out in the medical clinics of Basle, by W. Frey, who contributes the results of his observations in the *Zeitschrift für klinische Medizin*, Volume 72, Nos. 5 and 6. He finds that urobilinuria is a frequent manifestation of affections of the liver, denoting a functionally impaired organ if one can exclude, on the one hand, the occurrence of a diminution of the fecal urobilin, and on the other hand, an increased formation of urobilin, as by the destruction of red blood-cells. The administration of levulose is an important means of testing the functional capacity of the liver. In healthy individuals, alimentary levulosuria occurs in 10 per cent. of the cases, while in those suffering from hepatic disorders alimentary levulosuria occurs in 50 per cent. of the cases. Among these cases instances of cirrhosis are largely represented, although the symptoms may occasionally fail. The employment of galactose is of inferior value in this test. The determination of urea in the urine furnishes no criterion of any existing disease of the liver. The excretion of ammonia, however, is increased in hepatic disorders, and is exceptionally high in the cirrhoses. The diagnostic value of this sign is compromised by the existence of similar figures in the case of excessive meat diet, fever, and various diseases that lead to acidosis.

The determination of the amino-acids furnishes an important diagnostic criterion. These acids are regularly increased (above 0.5 gram N.) in the cirrhoses. The significance of this sign is all the greater in view of the fact that Frey observed this abnormality only in one case of amyloid liver, and in one case of marked congestion of the liver,

among a large number of cases that he had investigated. Among diseases of other organs, hyperacidaminuria was noted in pneumonia, typhoid fever, and pancreatic diabetes. The diseased liver is capable of disposing of ingested amino-acids as well as the healthy organ.

It is hoped that the development of these, as well as of other methods of diagnosis, will render possible the early recognition and differentiation of hepatic disease with a facility equal to that of the urinary diagnosis of diseases of the kidney.

FAVORABLE EFFECTS OF THE AUTOMOBILE ON CERTAIN NERVOUS DISORDERS.

The special literature of automobiling in its relationship to disease is very meager and imperfect, and it is still necessary to read miscellaneous descriptions of cases in order to come upon the favorable or unfavorable effects of relatively new methods of locomotion on diseases. There is nothing specific about the motion of automobiling, for it is merely a matter of petty shocks or vibrations, such as occur in railway trains, and, if automobile journeys appear to produce certain effects, it is quite safe to assume that railway travel will be followed by the same or similar consequences.

At a recent meeting of the Berlin Society for Psychiatry and Nervous Diseases (*Berliner klinische Wochenschrift*, May 22) Oppenheimer read a paper on habitual vertigo from which it appeared that this condition is less apparent to the patient when riding in automobiles or railway trains. In discussion Kron stated that he had seen the same sequence, but attributed it to psychic causes—distraction of the attention. He cited the case of a rope-dancer who suffered from vertigo when on the ground, but was never bothered while in the air. The psychic factor is naturally in evidence here, and the state of affairs is paralleled by the actor who always stutters while off the stage, but never while speaking his lines in a play.

Bernhardt stated that the patient with habitual vertigo feels in better spirits on an automobile or railway journey, and this is also true of patients with paralysis agitans. He would attribute the favorable result to the fact that the involuntary motion imparted by the vehicle antagonizes the sensations of vertigo and tremor. One of his patients with paralysis agitans takes several rides daily on an auto-omnibus.

Tubercle Bacilli in the Feces.

During the last few years numerous authors have published results of searching the feces of tuberculous patients for tubercle bacilli, almost all agreeing that positive findings are of little value, because they simply indicate that bacilli-containing sputum was swallowed by patients and not that the intestinal tract contains tuberculous lesions. However, most of this work has been done with clinical material only, that is, the final diagnosis afforded by a post-mortem examination was not available; mere absence of symptoms was considered to speak for or against the existence of tuberculous lesions in the intestines. Lately, the Germans have taken up this work, and profiting by their superior advantages in securing autopsies, have compared the results of examination for bacilli and the post-mortem findings. Thus Frieda Rittel-Wilenko, writing in the *Wiener klinische Wochenschrift*, April 13, 1911, tabulates twenty-nine cases in which feces were examined for tubercle bacilli, in some at autopsy only, in others both during life and at autopsy. In all but three cases in which bacilli were demonstrated tuberculous ulcers were discovered in the intestines at the autopsy, though in many of the positive cases no symptoms of these were observed during life and therefore no corresponding diagnosis made. The three cases in which bacilli were found in the absence of pathological lesions in the intestines must be explained by the assumption that bacilli were swallowed and escaped digestion by the gastric and intestinal juices. In such cases, however, the tubercle bacilli were very few in number, their demonstration being made successful only after the use of special methods such as the antiformin technique. Rittel-Wilenko's study again shows that the much discussed communication of Rosenberger, who claims to have found tubercle bacilli in 100 per cent. of cases examined, many of which gave no clinical evidence of either pulmonary or intestinal tuberculosis, must have been founded upon some error of technique, leading to contamination of the material by acid-fast bacilli resembling tubercle bacilli. The results show, in addition, the great importance of examining stools in cases where clinical symptoms are suggestive of tuberculosis: the finding of tubercle bacilli may help to clear up many an obscure case of chronic gastrointestinal disturbance, especially in young children, who are so frequently the victims of this form of tuberculous infection.

A New Physical Sign.

Textbooks on physical diagnosis usually state that the upper limit of the absolute liver dullness begins posteriorly at midline and only anteriorly crosses the middle of the abdomen. Any dullness posterior to the left of the midspinal line is not accounted for, as a rule, by any increase or transposition of the liver limits. Yet Grocco, who has already pointed out a neglected physical sign, the so-called Grocco's paravertebral triangle, in cases of pleurisy with effusion, again takes issue with the textbook descriptions. Careful physical examinations of patients, combined with the observation of anatomical and pathological material, have shown to him that even the normal limits of absolute liver dullness pass beyond the midspinal line and extend for from 3½ to 5 cm. to the left. In cases of enlargement of the liver the posterior boundary is, of course, moved still further to the left, sometimes reaching as far as 12 cm. to the left of the midline. Grocco has examined over three hundred normal and abnormal persons in reference to this point, and gives in the *Wiener klinische Wochenschrift* for May 11, 1911, detailed directions for demonstrating his new physical sign. Of course, the determination of the left boundary of the liver posteriorly should prove of interest in cases where enlargement of the left lobe is suspected. Whether such determination will prove of much clinical value remains to be seen; Grocco himself thinks that in the future this new physical sign will be elicited as an important part of the routine physical examination of the thorax and abdomen.

Acquired Tolerance to Local Irritation.

Our knowledge of what may be termed by contrast "subsensitiveness" or partial acquired immunity, keeps pace with what we know of anaphylaxis. This applies only to the accumulation of data, for we are in almost complete ignorance of the intimate nature of these processes. Partial acquired immunity seems to be a phenomenon of general occurrence. We are constantly becoming inured to all kinds of external and internal irritation. Anaphylaxis represents the personal peculiarity or idiosyncrasy. The two, however, may be seen side by side. A vender of spirits may acquire a remarkable tolerance to the potentially destructive action of his wares. Yet after he has developed some definite lesion, a polyneuritis for example, by reason of which he changes his habits, a very small abuse may cause the condition to recur. The subject of acquired tolerance to local irritation was discussed by Wessely at the recent meeting of the German Surgical Society (*Münchener medizinische Wochenschrift,* May 2). This, he states, is best studied in the eye. Irritation of the conjunctiva causes a slight increase in the albumin content of the aqueous (1/100 per cent.). He irritated eyes with subcutaneous injections of saline solution, and pencilling with iodine and nitrate of silver. Judged by the albumin content the eye reacted less after the third act of irritation, and after the seventh or eighth, immunity was present. The eye was at the same time rendered refractory to other forms of hyperemic irritation.

News of the Week.

New York's Vital Statistics.—For the first quarter of the year 1911, the mortality statistics for New York City show an actual increase in the number of births and marriages, and a decrease in the death rate as compared with the same period of last year. During the quarter 34,506 births were reported, an increase of 1,901, while the number of deaths was 20,876 against 20,660 in 1910, an actual increase of 216, but a decrease in the rate per thousand from 17.45 to 17. Comparing the average of the first quarter for the last five years with the same period this year, a decrease of 1,634 deaths is shown, of which 468 were of children under one year, and 1,099 of children under five years of age. The death rate in the same comparison fell from 18.33 to 17 per thousand. During the week ending June 10 there were 1,224 deaths in New York City, as compared with 1,398 for the corresponding week last year. Of these, 613 were of children under the age of five years. The deaths from typhoid fever were only one-half as many as during the same time last year.

Tuberculosis Boat.—The old ferry boat *Westfield*, which has been used for some time as a floating tuberculosis camp in New York, is to be moved from Corlears Hook Park to another berth just below the Williamsburg Bridge. This is being done so that the park may be improved.

Italy's Death Rate.—The Italian health authorities report that the death rate in the city of Rome is only 13 per thousand of population, thus giving the city the lowest rate in Europe. Throughout the rest of Italy the death rate for 1910 was lower than for any year since 1862.

Compulsory Antityphoid Vaccination in the Army.—On the recommendation of Major-Gen. Wood, Chief of Staff, Secretary of War Stimson has directed that hereafter all recruits to the army under thirty-five years of age shall submit to antityphoid inoculation. For over a year this measure has been voluntary, and the present order is the first step toward making the treatment obligatory throughout the army. The treatment will be given as soon as practicable after enlistment.

Sydenham Hospital.—It is reported that Sydenham Hospital, New York, is likely to close soon after July 1, the closing of the dispensary attached to the hospital on June 30 having already been ordered. The report of the County Medical Society in regard to the falsification of the hospital records in the Ewald case has been responsible for a decrease in the hospital patronage.

Tropical Diseases.—The College of Medicine and Surgery of the University of the Philippines, Manila, announces that it has in contemplation a publication on the subject of the surgery of tropical diseases or of the disease most common and frequent in the tropics. Reports, statistics, and other data bearing on the subject are solicited by Dr. John R. McDill, professor of surgery in the College and Chief Surgeon to the Philippine General Hospital.

Fire in Bellevue.—A small fire in the drying room of the new Pavilion A of Bellevue Hospital, New York, on June 13, was extinguished by the hospital's own fire fighters before serious damage was done and without alarming the patients in the wards.

Cornell University Medical College.—Fifty-five medical students, of whom seven were women, received the degree of Doctor of Medicine from Cornell University at the annual commencement exercises of the medical school held in New York on June 14. The two highest honors in the class were carried by women students, Helen Dudley of Brooklyn taking the first John Metcalf Polk prize of $300, and Elvira D. Dean of Mineola, N. Y., the second prize of $125. The third Polk prize was awarded to Wesley M. Baldwin of Yonkers. The class of 1911, as the last one entering the College before the degree requirement was enforced, will be the largest to graduate for some time. Next year's class at present numbers about fifteen. The retirement of Professor Rudolph A. Witthaus from the chair of chemistry, toxicology, and medical jurisprudence, which he has held since the opening of the college, was announced recently, and at a special meeting of the faculty, held on June 14, he was presented with an engrossed set of resolutions commemorating his years of service.

Dr. C. H. Chetwood of New York received the honorary degree of Doctor of Laws from Fordham University at the annual commencement exercises on June 14.

The Cartwright Prize.—Dr. Martin H. Fischer, holder of the Joseph Eichberg chair of physiology in the University of Cincinnati, has been awarded the Cartwright Prize of the Association of the Alumni of the College of Physicians and Surgeons, New York, for 1911.

Lectures on Psychology to Nurses.—Dr. Mary Lawson Neff delivered a course of eight lectures on psychology at the Women's Hospital, Philadelphia, during April. This course was first developed for the nurses in training in the Long Island State Hospital, New York, at the request of the late superintendent, Dr. Oliver M. Dewing. The lectures are given under the following titles: 1, The Nervous

Mechanism; 2, Fatigue; 3, How to Play; 4, How to Work; 5, How to Rest; 6, Habit and Personality; 7, Suggestion; 8, Mental Hygiene.

Civil Service Examination.—The New York State Civil Service Commission will hold on or about August 5, 1911, an examination for the purpose of filling the position of superintendent of the Syracuse State Institution for Feeble Minded Children. The position is open to men only, and carries a salary of $4,000 a year with maintenance for the superintendent and his family. Application blanks and further details may be learned by addressing the State Civil Service Commission, Albany, N. Y. Applications must be filed not later than July 28, 1911.

Rat Plague in London.—The health authorities of London announce that after a long period of quiescence the plague has again appeared among the rats along the river front of the city. The infection has been discovered at a wharf at Wapping less than a mile from Tower Bridge.

The Estate of One Physician Sues the Estate of Another.—At the time of Dr. William T. Bull's last illness Dr. Gerardus H. Wynkoop of New York was one of the attending physicians, and after the death of both men the executors of the Wynkoop estate put in a claim against the Bull estate for $2,500 for professional services. The claim being rejected, the Wynkoop estate sued to recover the amount, but the case was discontinued recently, the claim having been compromised for $600.

The Page Law.—The Court of Appeals of New York on June 16 declared unconstitutional the provision of the inferior courts act for cities of the first class which provides for a medical examination of women prisoners. The Court bases its decision on the ground that the act requires a magistrate to commit a person upon the report of a non-judicial officer. This reverses the order of the Appellate Division before which a trial case was brought.

Gifts to Charities.—Anticipating during his lifetime some of the provisions of his will, Mr. Lispenard Stewart of New York has made gifts of $25,000 each to the New York Eye and Ear Infirmary and to the Roosevelt Hospital. Mr. Stewart has for some years served as president of the board of directors of the former institution.

A plot of land comprising over five acres has recently been presented to the city of Yonkers, New York, by Mr. Alexander S. Cochran of that city, on which a hospital for cases of tuberculosis will be erected at a cost of about $50,000.

Dr. Allen J. Smith, dean and professor of pathology in the Medical Department of the University of Pennsylvania, received the honorary degree of doctor of laws from McGill University, Montreal, recently.

Dr. Milton B. Hartzell, professor of dermatology in the Medical Department of the University of Pennsylvania, has received the honorary degree of doctor of laws from the Pennsylvania State College.

Colony for Alcoholics.—The establishment by New York City of a hospital and colony for chronic inebriates is recommended in a report submitted recently by a special committee of the Board of Estimate. The committee recommends the formation of a board of inebriety to provide for such a colony, with accommodations at the outset for about 500 persons. It is estimated that an initial expenditure of about $450,000 will be required, and that the annual expense of the institution will be about $80,000; but it is believed that this method of caring for drunkards would be much cheaper and more satisfactory than the present custom of committing such persons to Bellevue Hospital or to the workhouse.

Legislation in Illinois.—The Illinois State Legislature recently passed a bill establishing the Illinois Surgical Institute for Children, and providing an appropriation of $60,000 for contruction and $15,000 for furnishing. Another bill has also been passed recently giving to counties in the State the right to acquire property on which to erect and maintain sanatoria for the treatment of residents of the county who are afflicted with tuberculosis. The right to maintain branch hospitals is also given. The Governor has signed both of these bills.

The Late Dr. Carl Beck.—At a meeting of the Board of Managers of St. Mark's Hospital, New York City, the following resolutions were adopted: "*Whereas* it has pleased Almighty Providence to call away our good friend and Honorary President, Dr. Carl Beck; and, *Whereas* by his untiring zeal and devotion to duty he has earned the gratitude of all connected with the institution; *Resolved*, that the Board of Managers of St. Mark's Hospital of New York City do and hereby express their deep sense of grief at the loss of their good friend, Dr. Carl Beck, and further express their heart-felt sympathy with and tender their condolence to his bereaved family; and *Resolved*, that the Secretary be instructed to spread these resolutions in full upon the minutes and that a copy of the same signed by all the members of the Board be forwarded to his widow; and *Resolved*, that a copy of these resolutions be published in the daily and medical papers.

Obituary Notes.—Dr. James A. Richardson of Salem, Ore., a graduate of the Medical Department of the University of California, San Francisco, in 1866, and of the Bellevue Hospital Medical College in 1870, a member of the Oregon State and Marion County Medical Societies, and formerly Mayor of Salem, died at his home on June 4, aged 71 years.

Dr. Charles H. Dixon of St. Louis, Mo., a graduate of the Missouri Medical College, St. Louis, in 1878, clinical lecturer in surgery and professor of rectal surgery in the Medical Department of Washington University, a member of the American Medical Association, the Missouri State and St. Louis County Medical Societies, the Association of Military Surgeons of the United States, and the City Hospital Alumni Medical Society, died at his home of cancer of the liver, on June 5, aged 55 years.

Dr. William Rush of St. Louis, Mo., a graduate of the Medical Department of Washington University, St. Louis, in 1901, lecturer on clinical chemistry and microscopy in the University, a member of the staff of the Washington University Hospital, and clinical assistant in the Dispensary, and a member of the American State and St. Louis County Medical Societies, died at his home after a short illness, on June 2, aged 44 years.

Dr. Clayton L. Rich of Fullerton, Cal., a graduate of the Hahnemann Medical College of the Pacific, San Francisco, 1897, and a member of the State and Orange County Medical Societies, died suddenly at his home, on June 3, aged 38 years.

Dr. Bolivar Antrobus of Beloit, Kan., a graduate of the Medical College of Ohio (Medical Department of the University of Cincinnati) in 1876, died at his home of pneumonia, on June 3, aged 75 years.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

MEDICAL MEETINGS AND OPINIONS ON THE STATE INSURANCE BILL—SPINAL RIGIDITY—OBITUARY.

LONDON, June 2, 1911.

THE Government has forced the insurance bill through the second reading by the aid of the closure. All appeals for delay were contemptuously refused, although a number of their own supporters joined in the request for "one more day" to discuss its principle. Mr. Lloyd George said, of course, his bill must go through this session and such amendments as had been proposed could be settled in committee. He then made the extravagant assertion that not one of those who had raised objections had read his bill. As to the doctors, he declared that their position would be raised, that the assumptions they had made were all wrong, that they would become independent of the friendly societies, and that the prices he had quoted were not fixed. He admitted that all reforms were likely to make some hard cases; for you could not widen a road without taking some one's land, and vested interests cried out for compensation. His bill would so improve the public health that he was not surprised vested interests might suffer; in fact, he was amazed that the undertakers had not sent in a protest. He passed on to dilate on the great benefits his proposals would confer on the most numerous class of the community, and here he seemed to let out a secret motive which has not been unsuspected. Every trades union, every workingman is to be benefited, and he was sure when the working classes see what they will gain it will not be for their leaders to criticise the scheme. Of course these classes are the most numerous, but they all have votes, and however excellent the provisions of the scheme may be it is somewhat of a vote-catching measure.

A great many meetings have been held throughout the country to discuss the insurance scheme, the general feeling being one of apprehension that much injury must result unless drastic amendments are made in the bill. The profession, therefore, adds its voice to that of the politicians, who have demanded delay. In this the profession seems earnest and united. Indeed, it may be said that never before has there been so decided union among all medical men. The committee which I told you was appointed by the General Medical Council set to work in earnest and very soon elaborated a report, which has been adopted. It is comprised in eight lengthy paragraphs recommending among other points that medical members should be on every authority dealing with the matter; that the free choice of the doctor be secured to every patient; that the health committees should be the administrators, and not the friendly societies. These and other points were submitted to Lloyd George before his speech in the House, referred to above.

The Royal College of Physicians has also held an extraordinary meeting and appointed a committee and requested the president to convey to the Government the opinion of the college that time ought to be afforded for further consideration. In opening this meeting the president made a suggestion with which I cordially concur. He asked whether it is imperative that medical benefits should be a necessary portion of state insurance, or whether it would not be wiser to let the community deal with its medical needs for itself. I have often put this same question.

The Council of the Royal College of Surgeons discussed the bill yesterday afternoon and expressed opinions quite as decided against the medical service being administered by the friendly societies; in favor of the profession being represented on all committees connected with this service, of all persons insured having the choice of their attendants, of an income limit of persons who could receive medical benefits, and of proper remuneration being assured for medical service done.

Yesterday, too, was a great day for the British Medical Association, which has been working from the first announcement of the bill to secure the position of the profession and to press on the Government the necessity for drastic changes in the proposals. The day before the "representative meeting" had been held and asked the Chancellor to receive a deputation, but, instead, he agreed to attend the adjourned meeting and answer questions. Accordingly, he came and was duly cross-examined. He was in his most conciliatory mood and succeeded in captivating his audience by concessions on some points and plausible explanations and corrections of misapprehensions on others, so that at the close of the interrogations a cordial vote of thanks was accorded to him, most of those present rising and loudly cheering.

In the evening followed a general meeting of the profession, organized by the association, but open to all. There the influence of the Chancellor was not so apparent, and many were asking what he had conceded, or whether he had promised anything absolutely. He certainly refused delay, for he said the bill must go through in August, and he said an income limit was impracticable. Others unkindly declared it did not matter what he conceded, as, like all his colleagues in the Government, he would contrive to get out of any inconvenient pledge. But these whisperings were, so to say, unofficial. The chair being taken by Dr. Maclean, a resolution was proposed by Macdonald approving the main objects of the bill, but pronouncing the present proposals unsatisfactory, and demanding delay until terms for medical benefits have been arranged with the profession.

Sir T. Barlow, president of the Royal College of Physicians, seconding, said they all knew the difficulty was the relationship with the friendly societies and how much their humbler brethren had suffered.

Mr. Butlin, president of the Royal College of Surgeons, said this was the greatest crisis of the profession for centuries, and he was much disappointed with the Chancellor, who had spoken charmingly and answered some questions satisfactorily, but others not so. He gave them to understand his bill must pass, refused an income limit under £160, and was bent on letting friendly societies administer the act. They must look to it that the scheme did not ruin many practitioners.

Sir Victor Horsley disagreed. He held Mr. Lloyd George had answered frankly where he could not accept their views and agreed where he could. It was the duty and altruistic wish of the profession to promote the health of the nation—the object of the bill. It was possible for a united profession to secure amendments.

Two cases among those exhibited at the Clinical Section excited a good deal of interest. The first

was shown by Dr. Harris as one of spondylitis with mulcular contracture in a man of 33, who was invalided from the army three years ago on account of constant pains in the back and shoulders, and who had relapsing fever in West Africa a year previously. At first the pains were severe and he felt his back and neck getting stiff and making him stoop, and he has continued to get worse. He had taken 10 grains of aspirin daily for the last two years, for if he left it off for two days the pains returned. The spine showed general kyphosis, was quite rigid; head held forward with very slight movements possible; chest rigid; breathing entirely diaphragmatic. The shoulders were rigid, owing to muscular contracture and spasm, but the joints were normal. Under chloroform the scapulæ would be freely moved, but the arms could not be raised above the horizontal, owing to contracture of the pectorals. Hip joints and lower extremities normal. No sign of rheumatism, and skiagrams showed no abnormality of either spine or thorax.

The other case was shown by Drs. Rolleston and Humphrey as rigidity of the spine. The patient was a man of 26, of healthy family, who was himself well until January, 1905, when he had acute rheumatism and kept to his bed six months. In December, 1906, he had another attack, in bed four months, and his heart affected. In April, 1909, a third attack, and his back and neck began to get stiff. In June admitted to St. George's Hospital with subacute rheumatic fever, and reacted to salicylates. Stiffness of the back on convalescence, which improved at Bath, but the stiffness varied from time to time. In May, 1910, stiffness passed off while at the seaside, but on returning to London came on again in three weeks and has continued since, and he complains of shooting pains in the back, which spread over the body. When placed on the floor the first part of the spine to touch was the tenth dorsal, the external occipital protuberance being 2½ inches from the floor—a position maintained under deep general anesthesia. A slight lateral curvature in the dorsal region to the right was compensated by a left lumbar curve. The head could be moved 1 inch vertically, 1¾ inches to the right, and ¾ inch to the left (measured by the chin). Under anesthesia these movements were suddenly stopped, as if by a bony obstacle. The right arm was smaller than the left, and movement at shoulder restricted as if due to contracture of the pectorals. Left arm normal. The thighs could be flexed to right angle. Chest flattened (¼ inch expansion). Breathing diaphragmatic (abdominal expansion 2 inches, and the muscles rigid). Apex beat in fifth space, in the nipple line; a mitral systolic murmur was present. Cutaneous sensation unaltered. Knee jerks present. Dr. Allpress Simmons provided the skiagrams and reported that repeated radiographic examinations during the last year did not suggest any bony ankylosis, but the appearance of the anterior common spinous ligament in the upper cervical region was compatible with calcification in that ligament.

Deputy Surgeon-General W. P. Partridge, late A. M. S., has died at the age of 80. He took M. R. C. S., 1853, and served with the Persian expedition, 1856-7, being present at the landing in Hallilah Bay and the bombardment and capture of Bushire and Mohumrah, for which he received clasp and medal. In the Abyssinian expedition he was in charge of the hospital ship *Star of India*, and was awarded the medal.

The death is reported at Cannes of Edward H. Douty, surgeon to the Queen Victoria Hospital at Nice and L'Asile Evangelique at Cannes. He was a Cambridge M.D. and a fellow of the London College of Surgeons.

THE CANADIAN MEDICAL ASSOCIATION.

(From Our Special Correspondent.)

MONTREAL, June 12, 1910.

THE week which commenced with June 5 was a great week in Montreal, regarded from the medical standpoint. On Monday, June 5, and on the following day the celebration in connection with the opening of the new medical building of McGill University took place. From all parts of this continent and from almost all parts of the world McGill medical graduates gathered to do honor to the occasion. It will be recalled that four years or so ago the then medical building of McGill University, most of which had been built only a few years, was nearly completely destroyed by fire. By the generosity of Lord Strathcona, who gave a splendid site for the building and contributed, in the first instance, the sum of $450,000, to which he added the other day $100,000 for equipment, a building has been erected and equipped adequate to the needs of and in keeping with the reputation of McGill University Medical School. The building is the largest of the university group of buildings, its frontage exactly facing the Royal Victoria Hospital and with only the road between it, 265 feet, with a similar length of frontage on the university campus. Its frontage on University Street is 171 feet and 114 feet on Carlton Road. The museum wing is in the form of a cross, 74 feet square. The building is four stories in height and of Montreal limestone, and the edifice is of steel construction, and fireproof. It would take too much space by far to describe the interior; suffice it to say that it is both ornamental and useful. It is arranged and equipped throughout in consonance with the latest views of medical science, always bearing in mind the convenience and comfort of professors and students. The opening ceremony was performed on the evening of Monday, June 5, and was made the occasion of a conversazione which comprised concerts, instrumental music, scientific exhibits of various kinds, library exhibit, and informal dance. The Governor-General of Canada, Earl Grey, opened the building at 9:15 in the evening in the anatomical laboratory, which, it is needless to say, had never been used for dissecting purposes. On the platform with him were Countess Grey and his aid-de-camp, together with Dr. Peterson, principal of McGill University, and Dr. Shepherd, dean of the medical faculty, and other notables. There was a brilliant assemblage, and everything passed off well. On Tuesday morning, June 6, Earl Grey laid the cornerstone of an addition to the Montreal General Hospital, which is virtually being rebuilt. Owing to limited space the hospital is placed in the most crowded part of the city, and the new buildings will rise to a height of seven stories. Indeed, the steel structure of the addition, to which Earl Grey laid the cornerstone, is already in place. The final celebration of the opening of the new medical building was an immense dinner given by the medical faculty of McGill to the medical graduates of that university. The dinner took place in the Windsor Hotel on Tuesday evening, June 6, and was attended by more than five

hundred guests, the great majority of whom were McGill medical graduates. There was a considerable amount of speechmaking at, or, rather, after the dinner, and a speech of some importance was given by Prof. J. G. Adami. Dr. Adami seized the opportunity to attack Bernard Shaw for some of his recent edifying remarks and writings. As to the malicious and slanderous writings concerning the medical profession in the introductory essay to his play, "The Doctor's Dilemma," in which he stated that the medical profession has not a high, but infamous character, Dr. Adami is sorry to believe that such an effusion being widely read by an unthinking crowd, some of the mud cast by Shaw is certain to stick. There were many other functions and festivities in connection with the opening of the new medical building, which were all largely attended and highly appreciated.

On Wednesday morning, June 7, the building just opened was put to its first use, that of the meetings of the various sections and general meetings of the Canadian Medical Association. The building, of course, is peculiarly well adapted for this purpose. The first general meeting was held in the anatomical laboratory, when the new president, Dr. George E. Armstrong, of Montreal, was installed. Addresses of welcome were given by Dr. Peterson, principal of McGill University, and by Dr. Guerin, Mayor of Montreal; reports and minutes were read, as well as the report of the Milk Commission of the Canadian Medical Association. The morning's proceedings were somewhat marred by the sudden indisposition of the new president, Dr. Armstrong, who was compelled to leave the meeting and go home.

The next general meeting was held on Thursday afternoon, June 8, when the address of the president, the address in surgery and an address on gallstone surgical treatment were given. The president had not sufficiently recovered to attend, and in his absence his address was read by Dr. A. Hutchinson, of Montreal. Dr. Armstrong first paid an eloquent tribute to the memory of the late Dr. James Bell, a foremost surgeon of Montreal, who died some three weeks ago. He then sketched briefly the history of the origin and development of the Canadian Medical Association, and referred in this connection to the high standard of education and ethics of the medical profession in Canada. The Roddick bill for Dominion registration was then discussed, which he classed as the most forward medico-political question before the profession in Canada to-day. With the adoption of this act he hoped that before long the councils of the English-speaking provinces would unite on a uniform standard of matriculation, although Quebec would have to remain outside on account of different educational methods. Dealing with matters of general polity, Dr. Armstrong laid stress on the necessity for careful preparation of vital statistics as the very foundation of sanitary science and practice, and urged that the association lend its powerful aid to securing a more efficient registration of births and deaths. Dr. Armstrong was especially emphatic as to the need of scientific research. Some of it may seem useless at the time, but he pointed to the fact that the apparently useless research of English scientists was to-day the basis of prosperity of the German and other peoples who could more readily appreciate the importance and usefulness of such research. Dr. Armstrong then discussed the problem of pure water and declared that in a country like Canada, with its abundant pure water supply, it was a reproach to any municipality to have water-borne diseases. He also dealt with the housing problem, as intensified by the introduction of swarms of immigrants, many with low standards of living and general habits which did not tend to healthy bodies, sound minds, or good citizenship. He urged that the medical association should work to demonstrate to municipalities that money expended in providing the so-called working classes with better houses, wider and better aired and lighted streets, would be infinitely well rewarded in a lessened expenditure for police courts, prisons, asylums, and hospitals, inverting the principle that "the means to do ill deeds makes ill deeds done."

CARBOLIC ACID IN TRACHOMA.

To the Editor of the Medical Record:

Sir: Having seen in your journal some reference to the identity of granular lids and trachoma, I would suggest that my successful treatment of granular lids might be used for trachoma.

I have treated three cases of granular lids this winter with carbolic acid. My method consists in applying to the everted lids a mixture of the acid and water (equal parts), well shaken. Cotton wound about an applicator is saturated and held against the granular surface and *immediately* washed off thoroughly with water by a camel's hair pencil. The lids are then held closed with a towel for a few minutes only. The patient can then open the eyes with a feeling of relief and no inconvenience. I make the application twice a week, and a cure is effected in six or eight treatments.

I have also used carbolic acid (equal parts water and acid) in the treatment of scarlet fever, by applying it to the tonsils (lightly or not, according to age, etc.) once each day, and all cases have recovered without complications. I have used the same application on the throats of children who had been exposed to scarlet fever, and I have the impression that it has a prophylactic action.

Robert Mason, M. D.

Exeter, N. H.

PSYCHOSIS FROM BELLADONNA POISONING.

To the Editor of the Medical Record:

Sir: I was very much interested in an article by Dr. M. Allen Starr, entitled "Acute Psychosis Due to Belladonna Poisoning," appearing in the Medical Record for June 10, 1911, in which he concludes his article by saying "A search through the literature has failed to reveal any similar cases on record, though cases of ordinary belladonna poisoning are not uncommon." Please allow me respectfully to suggest that perhaps he has not looked through the literature of the homeopathic school of medicine, for therein are the records of many similar cases. See, for instance, "Allen's Encyclopedia of Materia Medica." C. N. Payne, M. D.

Tuberculous Meningitis, with Leucocytosis and a Purulent Exudation Containing Many Bacilli. A Case Report. I. C. Walker.
The Public Health Laboratory. B. L. Arms.
Pregnancy as a Possible Relief for Visceral Ptosis. L. T. Brown.

Classification of Diabetes.—A. E. Austin states that one must make a valuation of the diabetic as one would

any damaged machine. As the normal human being can utilize 100 per cent. of the carbohydrate taken, especially in the form of starch (sugar tolerance is omitted because so variable), one has only to deduct the urinary glucose from the absolute carbohydrate intake and compare this difference with the latter to determine the efficacy of the body as a sugar-destroying agency. If, on the contrary, all the carbohydrate taken is found in the urine, one has only to determine the nitrogen of the protein food taken, which can be easily done by reference to Atwater's tables or practically any work on dietetics; one should multiply this by 3.65 according to Lusk, or 4 according to German authors, and deduct from this, in case no carbohydrate has been taken, the urinary glucose. Then one should compare this latter difference with the total possible glucose to be derived from the protein. This percentage of efficacy to oxidize dextrose will, of course, vary in the same individual as his tolerance increases or diminishes, but will inevitably distinguish the grades in the diabetic process better than the terms "mild," "moderate," and "severe," terms whose meaning varies with the different authorities.

Tuberculosis of Ankle.—M. H. Rogers concludes from a study of eighteen cases that the treatment of this condition in adults is different from that in children; the duration of treatment must be shortened, and in order to do this more radical steps must be taken in the beginning of the disease. Fixation is not sufficient to control tuberculosis of the ankle-joint in adults in a large percentage of cases, and even in mild cases it requires a long period of time. Chronic invalidism, meaning by that a certain mental condition that these people are sure to reach, when they are of no use to society, should be avoided. This can be done by an early diagnosis, and by outlining the treatment so that the end result is obtained within one or two years. A complete operation, a radical removal of the focus, should be performed before there is much involvement of the various joint surfaces, and it should not be undertaken only because fixation has failed. Better results can, undoubtedly, be obtained if this is done as soon as the diagnosis is established, and seems justifiable since fixation is not sufficient. Amputation has been necessary in over 50 per cent. of the cases. It should be advised when the process has invaded several joint surfaces, especially posterior to the astragalus. The results of amputation are good from the patient's point of view, and an artificial leg is much preferable to long-continued dressings and sinuses. The length of time of treatment should be diminished to within two years.

Problems of School Inspection.—W. P. Coues states that the necessity for school inspection in a community is in inverse ratio to the knowledge and intelligence of that community. It has been found in the work in the author's district that rarely is it through willful negligence that parents or pupils do not follow out the suggestions given, but rather through a failure to grasp their importance through ignorance.

Tuberculous Meningitis.—I. C. Walker reports the case of a young adult with physical signs of meningitis, fever, and leucocytosis, who showed on lumbar puncture a turbid spinal fluid containing 98 per cent. of polymorphonuclear leucocytes and very many bacilli, with the morphological and tinctorial peculiarities of the tubercle bacilli, yielding by animal inoculation the typical lesions of tuberculosis. The case is reported to emphasize the fallacy of diagnosing meningitis as due to pyogenic cocci from a turbid spinal fluid containing a large excess of polymorphonuclear leucocytes.

The Public Health Laboratory.—B. L. Arms describes the ways in which the physician and public health laboratory, each working together for a common purpose, can better the public health

Pregnancy as a Relief for Visceral Ptosis.—L. T. Brown states that the uterus as it enlarges from below upward gives the viscera the most perfect form of support imaginable, because it is always present and until the last month is constantly enlarging and, what is most important, it is present for five months. This last is particularly important, because it is a well-recognized fact that any muscle or ligament that is kept constantly on the stretch loses its power of complete contractility, and also that if such a muscle or ligament can be relieved of that strain for a period of time it will tend by the natural laws of repair to return to its original normal condition. In pregnancy such a support is given to the viscera and applied in the best possible way, with improvement in digestion and a gain of weight that cannot be accounted for by the weight of the fetus.

New York Medical Journal.

A Review of Methods of Examination in Heart and Blood-Vessel Diseases, with Special Reference to the Discovery of Therapeutic Indications. L. F. Bishop.
A Polygraphic Machine, Recording Automatically. T. E. Satterthwaite.
Stethoscopic Examinations. R. Abrahams.
Circulatory Disturbances of the Mesenteric Vessels. H. D. Collins.
The Radiographical Examination of the Gastrointestinal Tract. R. H. Boggs.
A Preliminary Report upon the Destruction of Surface and Cavity Neoplasms by Desiccation. W. L. Clark.
Diseases of Occupation. M. Korshet.
Involvement of the Trachea, Lungs, and Pleura in Grippe. R. E. Coughlin.
Acute Hematogenous Infections of the Kidney and Pyelitis of Pregnancy; Their Medical Treatment. L. Louria.

Examination in Diseases of Circulation.—L. F. Bishop concludes that of the results of physical examination the indications disclosed are nearly always the regulation of cardiac functions, rather than stimulation. Weakness indicates either a depressed activity of the heart, which may be on the whole conservative, or exhaustion of the reserve of the heart, which renders stimulation a desperate resource. An exhausted heart needs rest, not stimulating. It may be necessary to overcome a loss of tonicity in the heart muscle by digitalis, but that is not stimulation in the true sense, and in some cases of chronic heart disease it may be best to continue its use almost indefinitely, but, where possible, improvement of condition by proper diet, exercise, and conservation of energy should replace drug treatment.

Automatic Polygraphic Machine.—T. E. Satterthwaite describes a machine which he has devised for automatically registering the successive events in a cardiac circle.

Stethoscopic Examinations.—R. Abrahams states that this much can be said and should be said in favor of the time honored servant of the clinician: while all other instruments may come and go, the stethoscope will forever remain the handiest, readiest, and most trustworthy tool of the general practitioner.

Circulatory Disturbances of Mesenteric Vessels.—H. D. Collins alludes to a type of disturbance of splanchnic circulation to which attention should be particularly drawn, for but few of the cases have been reported. This type presents as its pathological lesion single or multiple small hemorrhages in the wall of the intestine, usually the ileum, without any thrombosis or embolus of the superior mesenteric artery or vein while lying between the mesenteric layers of the peritoneum. The hemorrhagic spots usually lie between the muscularis and serosa, or in the submucosa, and are placed diametrically opposite the mesentery. The areas vary from 1 to 3 cm. in diameter. In lieu of a better name the author has called this condition intestinal apoplexy. He has seen three cases illustrating this condition. In two of them the lesion was mild (only a single spot of hemorrhage), while the third had multiple areas. All the patients were subjected to operation and fortunately all recovered.

Radiography of Gastrointestinal Tract.—R. H. Boggs notes that the *x*-ray examination of the gastrointestinal tract should be not only radiographical and fluoroscopic but also cinematographical.

Electrical Desiccation.—W. L. Clark has found that a current from a static machine of large output with properly attuned accessories, when applied with correct technique and care, is capable of producing a superficial or a deep destruction of tissue by desiccation, or rapid depletion of its fluid element, which breaks up and disintegrates the cells. It has sterilizing, deodorant, styptic, penetrating, and stimulating properties. This specialized current has no particular affinity for abnormal tissue over the normal, but it is a simple matter to keep the destruction well within bounds on account of refinement of control. It is operative in all accessible lesions in which destruction is desirable, and works from without inward. Living tissue is destroyed by this means almost as readily as dead tissue. The rapidity of action appears to be directly proportionate to the density of the tissue.

Pulmonary Complications of Influenza.—R. E. Coughlin states that the two important sequelæ are pneumonia, with masked symptoms, and tuberculosis, which is insidious in its manifestations. In any case with grippe cough of six weeks' duration accompanied by râles at the end of inspiration at one or both apices, one is forced to conserve the best interests of the patient by diagnosticating the condition as pulmonary tuberculosis and instituting proper treatment for the recovery of the patient.

Hematogenous Infections of the Kidney.—L. Louria continues his article on this subject, emphasizing the importance of conservative treatment.

Gastric Ulcer.—J. E. Summers reports a case of chronic indurated ulcer of the posterior wall of the stomach successfully operated upon.

Radiography.—By E. M. Sala. See Medical Record, February 11, 1911, page 275.

The Knee-Jerk.—C. Pope describes a method by means of which it is believed that the patient cannot inhibit the knee-jerk. The patient, male or female, should sit in an ordinary straight-backed office chair, relaxing the entire body as far as possible. The feet are then pushed forward so as to extend the lower limbs comfortably. This position produces complete relaxation of the flexor groups of muscles of the lower limbs, and, as it is these groups of muscles that inhibit the response, it seems rational to believe that the inhibition would be prevented. With the limbs in the position indicated, and with the end of the toe of each shoe on a line, the clothing is drawn reasonably snug over the patella, with the thumb and forefinger of the left hand, in right-handed individuals. The three remaining fingers and the palm of the hand should rest on the thigh just above the patella. With a percussion hammer a gentle tap is given the tendon and its response or the absence thereof can be both seen and felt, for the palm and three fingers of the left hand will give an excellent index of the prominence and activity of the response. In this position reinforcement is most satisfactorily performed and a wider range of action obtained.

Kymographion.—D. E. Jackson describes a drum-spinning attachment to this instrument which answers the same purpose as the pendulum, or spring myograph, with the added advantages that it is smaller, cheaper, and much more easily and conveniently manipulated by students.

X-Ray Treatment of Ringworm of the Scalp.—L. D. Bulkley describes this method of treatment as carried out in London and Paris under Fox and Sabouraud. The unanimous opinion, after the discussion of the subject in the British Medical Association, was that the treatment has been perfectly harmless in many thousand cases in which the method was employed. As to the mode in which *x*-ray cures ringworm of the scalp it is generally agreed that it does so by the complete depilation and not by killing the parasites. There are no trichophytic hairs left to spread the infection a little while after the *x*-ray exposure. The baldness is not permanent, the hair returning in six weeks or so after the treatment.

Salvarsan.—By S. J. Meltzer. See Medical Record, April 22, 1911, page 742.

Pellagra.—S. R. Roberts applies Sambon's theory of the origin of pellagra from the bite of a *Simulium* to the occurrence of the disease as observed in Georgia. The author states the five propositions of Sambon, viz., that this disease is not due to the eating of maize; that its foci are in the neighborhood of streams infested with the *Simulium*, and have been so for a century or more; that the pellagra stations are closely associated with streams of running water; and that it is a periodic disease, agreeing in this respect with the seasons of activity of the *Simulium*. The author has obtained reports from thirty sources as to the occurrence of pellagra and the environment as regards streams of running water, and has found that in all cases they were in the close vicinity of the latter.

Directory for Wet-Nurses.—F. B. Talbot describes the organization in Boston of an institution at which wet-nurses may be obtained. This has accommodation for six women and their babies, and postal cards are sent out to physicians announcing that the nurses can be obtained at an expense of a fee of $10, used for the support of the institute. The methods of examination of wet-nurses and their babies are thorough and special attention is given to signs of tuberculosis and syphilis. The nurses are largely obtained from the maternity hospitals, and when they are in a rundown condition they are fed up before going out to work. They are carefully instructed as to the care of infants and are under the supervision of two excellent trained nurses. Their babies always go with them, no exceptions being made, for good reasons. They are supposed to receive wages of $8 a week, which they save for the future, but may receive less by arrangement if the families are not able to pay as much. If the demand continues to increase as it has the directory should be self-supporting in about another year.

Poliomyelitis.—S. Flexner and P. F. Clark have established the possibility of the dissemination of the infection of poliomyelitis by house-flies. The experiments showed that flies contaminated with the virus of poliomyelitis harbor the virus in a living and infectious state for at least forty-eight hours.

Hexamethylenamin in Colds.—A. Miller notes that under this treatment the irritating watery secretion of coryza stops; the fever, aching, and malaise of influenza cease; the threatening disease is averted. It should be administered as soon as possible after the nose begins to feel stuffy, and discomfort begins. If delayed till later in an old cold and after mixed infection has occurred its effects are less satisfactory. As regards dosage, the author thinks a larger amount should be used than is required for urinary antisepsis, and at the onset he prescribes fifteen grains,

to be taken in a glass of water four times a day. Copious water drinking is advised to lessen bladder irritation, which is the only ill effect, but occurs occasionally and disappears as soon as the medicine is discontinued.

Tuberculous Arthritis.—J. J. Nutt reports a case illustrating the necessity of frequent examinations during convalescence.

Sporotrichosis.—A. Beam reports a case of this condition.

Tobacco Dyspnea. J. D Reckitt.
Severe Burns of the Anterior Aspect of the Chest and Neck, with Part of the Lateral and Posterior Aspects; Three Operations for Skin-Grafting; Recovery. E. F. Travers and D. F. Maunsell.

Werdnig-Hoffmann Muscular Atrophy of Infants.—F. E. Batten reports a case which illustrates a type of progressive paralysis beginning in a child below the age of 12 months, affecting, in the first place, the trunk and proximal muscles, gradually spreading to those more distally situated, affecting the intercostals but sparing the diaphragm. The intelligence, sensation, and the visceral functions remain unaffected. Pathological examination of other cases shows that this progressive paralysis is due to a change in the cells of the anterior horn caused by some toxin or condition the nature of which is at present unknown.

Medico-Chirurgical Transactions.—J. M. Bruce contrasts the medical events of to-day with those chronicled one hundred years ago in the Transactions of the Medico-Chirurgical Society of London.

Reform Movement in Anesthetics.—F. W. Hewitt gives the recommendations of the Home Office Departmental Committee with reference to the question of deaths resulting from the administration of anesthetics.

Förster's Operation.—O. May states that there are two chief indications for posterior root section in cases of spastic paralysis: (1) the presence of such severe contracture as to make standing and walking impossible; and (2) the occurrence of painful cramps in the affected limbs. Up to the present the majority of reported cases have been those of various types of cerebral diplegia, though successful results have been obtained also in hemiplegia (arm), disseminated sclerosis, and spastic paraplegia from spinal caries. Impaired mental capacity is no contraindication; many good results have been obtained in imbecile children, who have after the operation been taught to stand and walk; indeed, in several cases considerable mental improvement has been noticed, perhaps as a result of the widened field of interest permitted by the newly acquired power of locomotion. It is, of course, obvious that good results are not to be obtained if the pyramidal tracts are completely destroyed. But in such a case—*e.g.* complete transverse myelitis—the paralysis would be a flaccid one, so that the question of operation would not come up for consideration. In all spastic cases, however severe the apparent paralysis, the latter is no contraindication, as it is impossible to tell until the spasticity has been removed how much power of voluntary movement will be obtained.

Pancreatic Sarcoma.—J. Sherren reports a case of the successful removal of a sarcoma from the head of the pancreas.

Referred Penile Pain in Intussusception.—G. E. Waugh states that the occurrence of paroxysmal attacks of pain referred to the end of the penis and suprapubic region in association with an intussusception appears not to have been recorded up to the present time. He reports three cases in which these symptoms were associated with a definite abnormal type of mesenteric formation. Some unusual features of intussusception formation appear to depend upon the presence of these mesenteries, and where their presence can be recognized beforehand by reason of this referred pain a departure from the usual traditional treatment of immediate operation can be justified with advantage to the patient.

Chronic Pancreatitis.—P. J. Cammidge states that since 1900 it has been gradually recognized that chronic pancreatitis is a much more common disease than had been formerly supposed, but even yet there is a tendency to regard it as of theoretical rather than practical interest. This is far from being the case. The author's experience during the past ten years has convinced him that it is a very real disease, and that if it were more frequently diagnosed in the early stages, when treatment is of most avail, much needless suffering and even loss of life might be avoided. Its clinical importance lies not so much in its early symptoms as in the effects it may produce if allowed to progress unchecked.

Gangrenous Pancreatitis.—G. A. Wright and E. L. Luckman report a case of this condition, with operation and recovery.

Tobacco Dyspnea.—J. D. Reckitt reports a case in which the depressant effect of the nicotine caused a sort of air hunger, the respiratory center being overstimulated in consequence of the want of tone in the first beat of the heart. It also seemed evident that the smoking of a foul pipe, saturated as it was with concentrated nicotine and tobacco juices of 10 years' standing, was the means of introducing into the system such a continuous amount of the poison daily that it indirectly, through its action on the heart, affected the respiration, causing inspiratory dyspnea.

Severe Burns.—E. F. Travers and D. F. Maunsell report a case of severe burns of the anterior and lateral aspect of the chest and neck. The points of interest in this case were as follows: 1, the practical absence of shock in a burn involving almost one-quarter of the skin area of the trunk, due to the prompt and continued use of picric acid and to the prompt attention to maintaining the body temperature by immediately putting the patient into a well-warmed bed; 2, the absence of septic poisoning due to the daily removal of all dead tissues and sloughs, with careful cleansing of the underlying tissues, and 3, the practical absence of deformity from scarring except at one point.

Comparative Nutritive Value of White, Standard, and Wholemeal Bread. L. Hill and M. Flack.

Fractures of the Patella.—C. B. Lockwood shows the advantages of operative over non-operative treatment of fractures of the patella.

Bursal Swellings About the Knee-Joints.—A. E. Barker, in a brief sketch of the enlargement of bursal cavities about the knee, not only directs attention to recognized swellings which have received more or less study, but also suggests that in some obscure conditions in this region an explanation may be found in enlargements of synovial tracts which are sometimes forgotten. In the

case of enlargement of some of them the author has strong grounds for the belief that they are the origin of large cystic swellings which have been, erroneously, believed to be due to hernial protrusions of the synovial membrane of the knee-joint. As to treatment, one may regard them as rudimentary joints, and deal with them as such. And as it is now recognized that joints may be dealt with freely by operation with a good prospect of the preservation of their functions, so may these bursal sacs.

Pharmacology of Strong Sulphur Water.—D. Brown states that the drinking of strong sulphur water causes an increased total nitrogenous output (8 per cent.) and an increase in the excretion of the phosphates (10 per cent.) on a strictly regulated diet. Further, the increase in excretion of endogenous creatinin (13 per cent.) proves its effect on the whole musculature of the body—and on the hepatic functions. The large increase in the excretion of body tissue (endogenous) uric acid (18 per cent.) proves its powerful influence in increasing the rate of metabolism of the nuclein-containing elements of the body.

Balneological Treatment of Disease.—W. R. Gore states that spa treatment produces two definite effects upon the bacterial growth that is the cause of most diseases: it prevents the growth of a large class of bacteria in the intestinal canal, and it causes the elimination of those toxins already circulating in the blood. All the accessory modes of treatment, the various baths and forms of massage, are designed to the same end; they all in some way help the circulation through the cell spaces and increase elimination through the various organs of the body when applied generally; locally applied they cause an increased flow of serum through the tissues treated, which is again a factor in antibacterial treatment, though the increased resisting power given to the tissues by a flooding out of serum should also be taken into account.

Cottage Nurses for Rural Districts.—H. Hick describes the system of district nurses established by the Holt Ockley Association. Each nurse receives four to six months' training at a cost to the association of from seventy to one hundred and five dollars. This amount is repaid by the nurse by the acceptance of a smaller salary for the first three years. A small sum is also retained by the association to form a bonus, which is given to the nurse at the end of three and a half or four years' service. The nurses are taught to make a bed, cook, wash and dress a patient, do ordinary dressings, take temperatures, pass a female catheter, and note symptoms, and to nurse a midwifery case. The hire of these nurses varies from fifty cents a week for the laboring classes to three dollars and seventy-five cents a week for the gentry.

Transmission of Trypanosoma Lewisi.—E. A. Minchin and J. D. Thomson conclude that the experimental results support their theory that the infection of rats with *T. lewisi* is not brought about normally through the rat eating the flea; and that the normal method of transmission is that the ripe, infective form of the trypanosome—the final form of the developmental cycle which it passes through in the flea—is regurgitated from the stomach of the flea into the wound made by the proboscis of the flea during the act of feeding.

Comparative Value of Various Kinds of Bread.—L. Hill and M. Flack, in their metabolism experiments on rats, have shown the deficiency of white flour. The Bread and Food Reform League urge the use of what is termed "standard" bread because of the prejudice against the brown wholemeal bread. In the authors' opinion the State should use all its powers to make standard and wholemeal bread the food of the children of the poor. White flour will continue to be eaten by the well-to-do because of its neutral flavor—it sets off the tastes of other foods, and white flour is necessary for the arts of pastry making. White flour robbed of the germ will keep easily, makes a pretty loaf, and saves trouble to miller and baker. But the whole meal is the real "staff of life," and no saving of trouble or liking of a nice-looking loaf should be the pretext for taking away substances essential for the growth of the children.

Berliner klinische Wochenschrift.

May 22 and 29, 1911.

The Transfusion Disease.—Schultz reports some added experience with defibrinated blood, with especial reference to the so-called "transfusion disease." The patient who received the blood was hopelessly ill of endocarditis, nephritis, and severe anemia. The blood was taken from a bronchitic subject who was otherwise healthy, and was first defibrinated. Three-fourths of an hour elapsed before it was infused. Within an hour a chill developed, followed by a fever of over 40° C. and marked prostration. The patient soon rallied, however, and the next day had improved notably in general appearance, subjective sensations and blood count. There were no evidences after transfusion of hemoglobinuria, edema, or collapse. The chill and fever do not seem to be anaphylactic in character and appear to occur in the absence in the blood of isoagglutinins and isohemolysins. The previous experience of the author in transfusion had led him to believe that the severe phenomena of transfusion disease were due to the presence of antibodies, and that the blood should first be tested for the presence or absence of the latter. In the present case, with the antibodies absent, a part of the transfusion syndrome still appeared and its rationale is obscure. The author is a warm partisan of transfusion with defibrinated blood.

Acute Benzol Poisoning.—Buchmann writes briefly but monographically on acute benzol and benzine poisoning, reporting a case of the former. It has long been known that benzol is highly toxic. It is extensively used in the arts for the preparation of nitrobenzol, anilin, phenol, and countless derivatives and also as a solvent for the recrystallization of many pharmaceuticals. It is sometimes popularly confounded with petroleum benzine, because of the similarity of their familiar names. Benzol may act as a chronic poison with production of headache, vertigo, anorexia, and tinnitus in paroxysms. Autopsies show fatty degeneration of the liver, kidneys, and blood-vessels. Acute benzol poisoning is much more important and is due to the inhalation of the vapor in massive amounts. The symptoms include those present in the chronic form, with the addition of vomiting, cyanosis, coldness of the surface, dilated pupils, motor excitement, and convulsions followed by paralysis. Benzol inhalation has been known to cause death *d'emblée* without warning symptoms. A characteristic phenomenon, provided death does not intercept it, is the transformation of hemoglobin to methemoglobin, which accounts for the peculiar appearance of the face. The erythrocytes show both fragmentation and attempts at regeneration. Benzol escapes in part by the urine (as paired sulphuric acid and glycuronic acid) and in part by the lungs. The author gives in detail a fatal case in a worker in chemicals. Death occurred very promptly after exposure to a large amount of vapor, and with the exception of marked hyperemia of the internal organs nothing was found at autopsy, nor could benzol be recovered from the body. The diagnosis of hyperacute benzol poisoning was not disputed and the victim's accident insurance claim was paid.

Familial Eosinophilia.—Klinkert refers to the subject of diatheses, under which some pathologists now range eosinophilia. This phenomenon is believed to represent an acquired anaphylaxis, since it develops as readily in diseases due to gross parasites and after various kinds of serum injection. It is also known to occur in certain forms of bronchial asthma, mucous colitis, spasmophilia,

etc. Experiment has shown further that the syndrome in which eosinophilia occurs has some connection with irritation of the branches of the vagi, and with a certain disproportion in size of the intrathoracic organs (small heart and arteries, large lung surface). In other words it comes in contact with the so-called exudative, spasmophilic, asthenic, lymphatic, and scrofulous diatheses of ancient and modern writers; for these conditions, intended to represent distinct states, shade into each other to such extent that no sharp boundary lines can be drawn, while sometimes the terms are frankly synonymous. The author cites a familial case (two generations). The children exhibited eosinophilia which ranged from 8 to 15 per cent. The oldest showed anaphylaxis to fish albumin; the next in age exhibited dermographism, hay fever, and Chvostek's sign; the fourth had hay fever and ordinary bronchial asthma; the fifth had mild Graves' disease, Chvostek, and angioneurotic edema after eating strawberries and truffles. The condition was evidently inherited from the father, who suffered from periodic attacks of painful nervous hyperchlorhydria. His eosinophilia was 6 per cent. Subjects of this sort are believed to react more markedly to sera than others. The eosinophilic syndrome, in as far as it is associated with vagotonic excitability, is said to be influenced favorably by atropine and adrenalin.

Metastatic Purulent Focal Pneumonia from Tonsillar Abscess.—Franz Cohn states that this sequence is not mentioned in standard works, the nearest approach thereto being mediastinitis from a burrowing abscess of the tonsil. A tonsillitis may often be associated with a pulmonary inflammation, but the latter is not a metastasis from the former. The fact that the author's patient recovered may be thought by some to militate against the acceptance of the finality of his diagnosis. The female patient, aged twenty-three, of good physical antecedents, visited the clinic for an ordinary quinsy of the left side. The abscess was incised and evacuated. The lungs were examined and found normal. The patient had a rise of temperature which persisted after the operation despite gargles of hydrogen peroxide and cold compresses. The tonsil was still red and swollen, but incision gave no further escape of pus, although a purulent secretion appeared later. The examination was negative for diphtheria bacilli. In the meantime vague pulmonary symptoms had set in—pains, purulent sputum (no tubercle bacille or pneumococci), and a Röntgen shadow over the right apex. First diagnosis, infected intrathoracic lymphnodes. For the next three weeks patient showed a typical curve of sepsis, and the sputum contained an abundance of streptococci. There was no surgical intervention as patient was not critically ill. She made a spontaneous and complete recovery. The lesions in the lung were evidently infarcts and not abscesses.

Anesthesia in Labor.—Strassmann considers this subject from all points of view and first of all its *raison d'être*. The suffering of labor is physiological throughout and the personal equation of women from this point of view shows the greatest variations. It is impossible to state in advance to what extent a given woman will suffer. Pain, if physiological, should be present for a useful purpose. The cry which results from the pain is followed by a deepened inspiration with resulting increased oxygenation of the maternal blood and eventually of that of the fetus. Painless labors are very largely pathological—precipitate delivery, labor in women with tabes and myelitis, and to some extent labor in placenta previa and edema of the vulva. But with a certain amount of pain labor should correspondingly advance to be physiological. But pain alone is never an indication to interfere. If chloroform be given to quiet excessive pain the beneficial effects of pain are antagonized. Labor does not advance so rapidly and the cessation of the cries interferes with aeration of the blood. When does pain really become pathological? If it is severe enough to cause raving and clouding of consciousness or in any way to render the woman's psyche abnormal it demands relief. When such degrees of pain are present labor is usually pathological, dystocic, from some obstruction to delivery. Broadly speaking, anesthesia is indicated in two classes of cases: first, if operative intervention is required, and if the labor is to be spontaneous. The first class may be left out of account as self-explanatory. The second class comprises first cases which may be relieved by anodynes, like chloral and morphine, which are used by many accoucheurs almost as routine resources. At the present day chloroform is used chiefly at the last moment before expulsion of the head, when there is no longer any possibility of interference with the natural march of labor. As for lumbal and sacral analgesia in spontaneous labors the author appears to be adverse to their use. Of comparatively unknown resources he merely mentions painting the nasal mucosa with cocaine and the use of suggestion. The article is to be continued.

Deutsche medizinische Wochenschrift.

May 25, 1911.

Bilateral Thrombosis of Femoral Veins After Severe Colitis.—Riedel mentions the unusual interest expressed at the present time in the subject of thrombosis of the crural veins. This may be unilateral or bilateral, septic or aseptic, and may proceed from lesions of the uterus, bladder, or rectum. The cause of infection varies (streptococcus, *B. coli*, etc.). The author reports two personal cases of bilateral thrombosis following severe colitis. Both patients recovered, so that the nature of the complication could only be surmised. The questions which require answers are as follows: 1. How did the colon lesion determine thrombosis of the crural veins? 2. Were the thrombi infected? 3. Why should the course show notable variations? The last question is suggested by the fact that the second case, notwithstanding its occurrence in an old subject, pursued an abnormally mild course, undergoing complete resolution in from two to three weeks. The author seeks to answer these questions provisionally as follows: The thrombosis was due to penetration of the *B. coli* from the intestine to the mesenteric lymphnodes, thence crosswise into minute venous radicles, and so to the hypogastric and femoral veins. No infection—or at most minimal infection—occurred. Differences in course were due to the fact that in the mild case the obturation was incomplete.

Renal Tuberculosis.—Barth's summary best indicates the scope of his paper. We must recognize the possibility of recovery in cases of urinary excretion of bacilli in so-called closed tuberculosis of the kidneys. But as soon as purulent infection occurs with a focus opening into the kidney pelvis, recovery does not take place, and the disease is propagated both into the kidney and down the urinary passages. Recovery may take place through nephrectomy in unilateral cases—a very safe procedure. Even if the disease has extended downward the outlook for recovery is not wholly compromised, although not over one-quarter of all cases recover if the bladder is attacked. In other words tuberculosis of the ureter of the affected side does not tend to increase the risk or outlook for operative recovery. In cured cases of vesical tuberculosis the bladder remains permanently afflicted, the patient suffering from desire to urinate, especially at night.

Tertiary Syphilis without Secondary Manifestations.—S. Gottschalk reports a case of gummatous osteitis of the ninth dorsal vertebra, associated with high fever, eight weeks after the primary infection. There had been no secondary manifestations.—*Medizinische Klinik.*

Society Reports.

THE MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

Meeting Held May 15, 1911.

THE PRESIDENT, DR. REYNOLD WEBB WILCOX, IN THE CHAIR.

Suction Drainage—A New Form of Air Pump Which Will Siphon.—Dr. NATHAN G. BOZEMAN said it was a well-known fact that water which divides in falling from a reservoir down a narrow tube carries air along with it, and if there are apertures in the side of the tube though which air enters this also is carried along. He first applied this principle of continuous suction for drainage in 1889, and the instrument for its accomplishment, a description of which he published at that time, was original with himself. It was his desire to bring the method again before the profession because of late some interest had been expressed in it. (See MEDICAL RECORD, April 15, 1911, p. 701.)

Intubation for the Relief of Acute Diphtheritic Stenosis of the Larynx, with Special Reference to the Treatment of Subacute (Retained) and Chronic Intubation Cases.—Dr. HENRY L. LYNAH, in this paper, said there was no operation in surgery which gives such satisfactory results as intubation of the larynx when death seems imminent. The whole credit for this masterly procedure belonged to the late Dr. Joseph O'Dwyer, and no one had been able to improve upon it. To be proficient in it one must know when to intubate and how to intubate. Having described the details of the operation, he stated that no force should be used in introducing the tube, as forcible intubation during a spasm would usually result in a false passage. In the face of local pathological processes it was best to select a tube one-half size smaller than was indicated by the age of the patient. It was extremely rare for a tube to fall below the vocal cords. He could recall only three instances, and in them the cause was forcible extraction, shoving the tube down in front of the extractor. It was necessary to differentiate laryngeal stenosis from various other conditions giving rise to embarrassed respiration. Its most marked characteristics were hoarseness of voice, dry, barking, hoarse cough, long-drawn inspiratory murmur ending in a peculiar click like hiccough as the glottis closes, and sawing, stridulous expiratory murmur of high pitch which gradually increases in severity. The supraclavicular fossæ and sternal notch became depressed and the epigastrium markedly retracted The aspirate pulse, which was full and bounding, disappeared on inspiration. The color was usually good, the face being flushed, and cyanosis was not marked until the last stage. Having mentioned the special features of the three stages, he said intubation should never be done in the first stage. A large dose of antitoxin would frequently ward off the necessity for its performance, but he had had little or no success with the much-lauded croup tent during this interval. On the other hand, one should never wait until the patient was in extremis. The best guide was the pulse, and when this became markedly aspirate, and at the same time there were progressive attacks of dyspnea accompanied by great restlessness, we should always intubate.

As each case had its own special characteristics, no definite rule could be laid down as to the time when the tube should be removed, though all authorities were agreed that the time of wearing the tube had been shortened since the introduction of large doses of antitoxin. At the Willard Parker Hospital formerly, when the doses of antitoxin were small, the tube was usually allowed to remain in the larynx about seven days. In a series of cases in 1907, when the doses were large, in 60 per cent. of the cases the tube was dispensed with on the third to the fifth day. In the latest record at the hospital, in 1910, the time interval was again shortened. The conditions for the removal of the tube were normal temperature, pulse, and respiration, the throat free from exudate, and the cough loose. This was usually about the fourth day. Reintubation was required immediately when adductor spasm occurred. In other cases this was called for in about two hours in consequence of subglottic swelling, plus swelling and edema recurring after the removal of the pressure of the tube. Again, there was a type of case which remained without the tube for two to three weeks, with slowly progressive "croupy" spells and a tendency to become worse at night. Here there was a gradual narrowing of the lumen by the hypertrophic subglottic tissues, and this was one of the most frequent causes of retained and chronic intubation cases. In these cases reintubation was often impossible, and one should never attempt this without having tracheal instruments at hand. In autoextubation cases the severe type usually occurred during the first week of the disease, and might be continued at intervals until the fourth week It appeared to be due to an early diphtheritic paralysis. On account of regurgitation such patients were difficult to feed and gavage had to be resorted to. Many of the acute types were complicated with bronchopneumonia, and the plugging of the tube with thick, ropy mucus caused it to be expelled. The treatment of these persistent autoextubation cases was at times very difficult, though Dr. Lynah had found this facilitated by using the caliber tube of O'Dwyer, modified with a slight retaining swell at its lower end, especially when mucus was causing the obstruction In other instances the reflex spasm was so great as to cause expulsion of any tube, and tracheotomy had to be resorted to in order to save life. The subacute (retained) type consisted of the cases which were prolonged over the usual intubation period, of one to two weeks, and, having worn a tube for from one to three months, subsequently recovered without surgical procedure or treatment by "special tubage." In these cases there was marked ulceration of the larynx, with a moderately hypertrophic condition. A rather curious circumstances was that the deep ulcers in healing have a tendency to increase the lumen of the larynx and trachea rather than to diminish it. During the past year he had collected fifty-two cases of this subacute type which were not treated by "special" tubes. Out of this number only two passed beyond the six months average of the subacute or retained stage to become chronic. In the chronic type the local pathological process resulting from the degree of severity of the diphtheritic membrane played the most important rôle in the etiology In these chronic cases O'Dwyer used prolonged tubage, but he did not dwell to any great extent upon the pathology, nor did he advise treatment by special tubes. In the special tubes there was an increase in one or more diameters of the "regular tube" of O'Dwyer, from the head and neck to the retaining swell or from the retaining swell to the end of the tube. We had (1) special laryngeal tubes for obstruction in the larynx; (2) special tracheal tubes for stricture at and below the cricoid cartilage, following cicatrices from laryngo-tracheotomy and tracheotomy; and (3) bridge tubes. By the last was meant a tube with a mechanical device which could be attached after having had to perform tracheotomy in order to save life in the chronic type when reintubation was impossible. To set this device on a tube a laryngotomy was also necessary, and it had been his practice to perform this in exploring the larynx and trachea in these cases. There were certain cases, however, which resisted all special dilation measures, so that more radical means had to be resorted to. In such Dr Lynah had tried to effect a cure by dissection of part of the hypertrophic tissue in the larynx and thorough cauterization with silver nitrate.

He had met with fair success, and two of the cases healed by primary union, but, owing to secretion and infection, healing by granulation was all that could be expected in the majority of these cases. He found that the dilating tube so increased the lumen of the larynx as to separate the cartilages and prevent their becoming fused again by the new cicatricial tissue so that the increase in the lumen appeared to be permanent. Among 3,035 intubation cases treated in the hospitals of the Department of Health during the past seven years he had been able to collect only 37 of the chronic type, and of these 22 recovered and were still alive so far as known. Having referred to the valuable contributions of Dr. John Rogers to the subject of chronic intubation and described the special tube the latter had devised, the speaker expressed the opinion, the result of long and careful investigation, that the whole basis of the laryngeal changes in intubation is laid down in the beginning, in the acute diphtheritic exudation; the future course of the lesions being governed by the severity of this. In some instances the exudate clears up more or less promptly, permitting the larynx to return to its normal condition. In others the exudate does not resolve, and the case becomes one requiring more or less prolonged intubation. This is the turning point for the outcome of all the subsequent changes: the growth of fibroblasts and of new connective tissue, at first hypertrophic, but finally dense and sclerotic. In these chronic tube cases the tube acts virtually as a foreign body on the unresolved diphtheritic exudates. Dr. Lynah gave a practical demonstration of extubation and intubation in a little girl who is one of the chronic cases at the Willard Parker Hospital, and also presented ten other patients illustrating various phases of the subject.

Dr. Ira Van Gieson gave an interesting demonstration of gross and microscopical specimens of the laryngeal lesions in diphtheria and chronic intubation.

Dr. John Rogers said he would like to add two or three observations to the points brought out by Dr. Lynah. According to his experience, the tube should be worn for from two to three years. In one instance this period had to be extended to forty-three months. The results were invariably successful, and, indeed, prolonged intubation was the only way in which these cases could be cured, since operative procedures had proved a complete failure In cases in which tracheotomy had to be done the prognosis as regards the voice was bad. There was one difficulty about extubation which deserved consideration. After one had worn one of these wide-mouthed tubes for a long time the abductor muscles became atrophied, and as the adductors retained their normal vigor there was great danger of the patient's choking when the tube was removed. This was particularly the case if the child were extubated while perfectly conscious; but if the removal was done under deep anesthesia it made no difference whether the abductors were atrophied or not. After the tube had been taken out the only way to obviate the trouble resulting from this muscular atrophy was to have the patient wear an exceedingly small necked tube for several months in order to allow the abductors to recover their tone. Strictures of the larynx and trachea were entirely amenable to treatment by intubation, and whenever, after extubation, it was discovered that a stricture was beginning to form, the tube should be promptly put back. In this way we could prevent an immense amount of future trouble. It was the characteristic of cicatricial tissue in every hollow tube in the body to contract and form strictures, and so here the contraction would invariably go on increasing if left to itself. In the end we would be obliged to perform tracheotomy, and thus have all our trouble over again. It usually took from two to three years for a stricture to lose its ability to contract. Every one of the cases in which hypertrophic laryngitis occurred could be cured by intubation, by means of properly modified tubes to exert pressure on the hypertrophied tissues.

Dr. Matthias Nicoll, Jr., said that the remarkable work accomplished by Drs. Lynah and Rogers constituted an epoch in the history of intubation. While O'Dwyer was entitled to everlasting renown for his brilliant achievement, his opportunities for observation were limited on account of the comparatively small service at the New York Foundling Hospital, and he had very little conception of the pathological problems involved in this matter. He would allude, though with some hesitancy, to one point upon which Dr. Lynah had not touched. In a very large diphtheria service like that at the Willard Parker Hospital there were constant calls for the reinsertion of tubes. The question was whether to go on with tubes of the same size or to run up the caliber. He believed that the increasing of the caliber to an inordinate degree was responsible for the unfortunate condition met with in a number of these cases The use of tubes too large for the age of the child must inevitably be attended with serious pathological results. The alternative was to put back the same sized tube as before—thus, for instance, in a child three years old going on with a three-year-old tube. This was perhaps impossible in a very large service, but at the Foundling Hospital he sometimes put back the same tube forty times.

Dr. Eli Long said that Dr. Lynah's work at the Willard Parker Hospital was beyond all praise, and he believed that intubation had probably saved more children's lives than any one thing.

The Vaccine Treatment of Typhoid Fever.—Dr. James G. Callison read this paper. (See page 1129.)

Dr. Austin W. Hollis said that no one observer seemed to have seen a sufficient number of cases to be able to express an altogether definite opinion in regard to the vaccine treatment of typhoid. We now, however, had a record of 303 cases, with 16 deaths, giving a mortality of 5 per cent. This, he believed, was as low a death rate as we could ever hope to attain in typhoid by any kind of treatment whatever, and it was certainly remarkable that such a gratifying result should have been reached so early in the history of the vaccine method. Personally, he had previously reported 11 cases, with no deaths, and he was now about to report to the New York Academy of Medicine a second series, of 39 cases, with 2 deaths In one of these fatal cases the patient died in thirty-six hours after admission to the hospital, and the other in five days, and both were in extremely bad condition when admitted. The first was an Italian woman who had been confined three weeks previously. The average duration of the cases was 32 days, but two of them were very long, one of them lasting 112 days and the other 80 days. Excluding these two cases, the average was about 25 days. No bad effects, so far as he knew, had ever been observed from the vaccine treatment, and under it the typhoid state was rare. If after the expiration of twenty-five days no result from the treatment had been noted he thought it should be abandoned, as these long septic cases could probably be more successfully dealt with by other means As to the dosage, he usually commenced with 50,000,000 every other day. This amount might be gradually increased, but he never went beyond 500,000,000. The small mortality under the vaccine treatment (5 per cent.) certainly offered encouragement to go on with its use, the average mortality from typhoid in the New York hospitals being something over 10 per cent.

Dr. George E. McLaughlin, Laboratory Director of Christ Hospital, Jersey City, said his observation of the vaccine treatment included only thirteen cases and he thought conclusions ought scarcely to be based on so small a number. He had used vaccines of different types, and the results under all were identical In every case

treated the vaccine seemed to exert some influence, and there were no deaths. At first he employed fairly small doses—under 50,000,000, but, concluding that these were not sufficient, he increased the dose to 100,000,000, and finally to 500,000,000. In this method of treatment the best results were to be obtained when the physician was a man who had had personal experience with the vaccine, one who was close to the laboratory and able to carry out all the little details required.

Dr. Callison, in closing, said that the work done by the British Commission was exhaustive as regards the prophylactic dosage. He believed that the sick patient would react to the vaccine in the same way as a well person, and that the proper dose for the treatment of typhoid was the same as the prophylactic dose.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

239th Regular Meeting, Held April 7, 1911.

Dr. Joseph D. Bryant, President pro tem, in the Chair.

An Illustration of the Bad Results of Paraffin Injections in Facial Disfigurements.—Dr. Robert Abbe, in presenting this patient, said that the case illustrated the detrimental effects of the use of paraffin to remedy facial deformity. The patient was a stenographer who had suffered in early youth a hemiatrophy of the lower jaw with depressed cicatrix on one side, due to bone necrosis following caries of molar teeth. To remedy this facial deformity she visited an able surgeon in this city, who injected paraffin on both sides with apparently excellent cosmetic effect satisfactory to the patient and himself for more than two years. The paraffin had been injected at a temperature of 110° F., and to overcome the depression in the cheek a rather large injection was given in that part, which puffed out the cheek. This was well placed and raised the scar, but it also made a mass which later extended across the lip. During the past year there had been a progressive settling of the paraffin into the chin, giving it a very dark color in the daytime. Now the entire breadth of the chin was of dusky violet hue and adamantine quality due to the setting of the paraffin into areolar and cutaneous structures, leaving but a thin layer of skin stretched over all, with a long crease below the chin, which opened spontaneously and oozed lymph. The patient was present in the hope of eliciting some idea of method of correction. One thought suggesting itself as a possible remedy was the use of heat sufficient to raise the temperature of the imbedded paraffin to model it into better shape, but this was a delicate procedure. Personally the speaker did not feel inclined to touch it. If some temperature change was brought about it might make it plastic and modeling possible. This might be done, but where it had now come to the surface he doubted if this could be done with safety. Dr. Abbe said that he had never used paraffin injection, for he had never thought that it was a safe procedure. Since it was in vogue, however, he presented this patient so that by observation the possibility of ill effects from its use might be seen. He had seen three cases in which women's faces had been badly marked, although the intention in each case was good. He recalled cases of two other ladies who had submitted to this treatment for obliteration of furrows in both cheeks, where the paraffin made two masses of yellowish white as broad as the finger on both sides of the face. The ladies wore veils and gave up society because of this deformity. His purpose in presenting the case was to illustrate what may happen from what may at first seem a good procedure.

Dr. J. A. Blake said that the condition was a chronic inflammatory process occurring about the paraffin, and that the mass consisted chiefly of the infiltrated paraffin. As to modeling he did not think that that was possible because, as he understood it, connective tissue infiltrates the paraffin so that it does not exist in a mass that could be molded. He would leave it alone.

Dr. C. S. Bull said that these paraffin injections about the face did not often, even after long intervals of time, either soften or disappear by absorption. In one of his cases he had used it on a lower lid which had been affected by entropion. As there had not been enough cutaneous matter left to permit of an operation for eversion of the lid, paraffin was injected at a temperature of 110°, producing a perfect result on the inversion of the lid. This had lasted for four years, with the same hard, deep yellow lump occupying the entire diameter of the lower lid and producing a very marked facial disfigurement. He also recalled another case in which the disfigurement had lasted for three years, with the same result. Since these unfortunate cases he had not done any paraffin injections for inversion of the lid because of the permanent disfigurement produced.

Dr. Abbe, closing the discussion, said that although the effect was detrimental, still the ladies aiming at cosmetic improvement desired these things, and got frightful results. The distressing feature happened when it came to the surface long afterward, and he did not see any way of improving the condition even if the wax was modeled. He did not want to touch it, for modeling it would bring it to the surface. He said that he did not think that there was any chance for plastic work, and he also thought that the condition was one involving the lymphatics.

Oxyuris Appendicitis.—Drs. R. L. Cecil and Kenneth Bulkley presented a preliminary report on oxyuris appendicitis, based on the study of 112 cases of appendicitis in children, with a control series of 35 autopsy and other appendices. Dr. Cecil opened the discussion with a brief review of the literature on the subject. Discussing the material at hand, he found that only 8 per cent. of autopsy appendices in children contained oxyuris, while nearly 17 per cent. of the cases of appendicitis in children contained either oxyuris vermicularis or trichocephalus dispar, or the eggs of these parasites. In all the cases thus far examined definite pathological lesions apparently due to the worm were found. The typical oxyuris appendix he described as being swollen and somewhat rigid, but the serosa is still smooth, pale and glistening. The lumen of the appendix is filled with bloody mucus in which can be seen writhing one or more oxyurides. Minute ecchymoses or hemorrhagic ulcers may be observed in the mucosa at various points. In some instances the parasite may be found firmly attached to the mucous membrane; and sections taken through such a point show the oxyuris burrowing beneath the mucosa, and producing more or less necrosis of the tissue. Occasionally one of these worms becomes completely enclosed in a fibrous capsule. Dr. Cecil demonstrated the various lesions produced by oxyuris with lantern slides. In concluding, he said that the studies which he and Dr. Bulkley had made, although as yet incomplete, had already shown that oxyuris or trichocephalus were responsible in New York for one out of every five or six cases of appendicitis occurring in children between the ages of two and fifteen.

Dr. Bulkley then continued the discussion by drawing a clinical picture of the disease. He emphasized the low temperature, pulse and leucocytosis, and the fact that the patients did not appear ill. The pain was throught at times to be rather characteristic and was described as gnawing, or scratching. He then cited the case of one woman who, following appendectomy, had been relieved of an intestinal oxyuris infection of twenty years' standing. Surgery he considered to be the rational method of treatment of intractable cases of intestinal infection by oxyuris.

Dr. R. Abbe said that he had had but one case of pinworms in an appendix. In that case there were about twenty, and one pinworm was found boring through the

mucosa and the wall of the appendix. The type of appendicitis which one sees most often to which this would apply was that in which there were a number of perforating ulcers.

Dr. J. A. Blake said that this paper was very important to the pathologist. He said that there did not seem to be any reason why the ulcers produced by these worms in childhood might not be the cause of strictures leading to attacks of appendicitis in later life.

Dr. R. L. Cecil said that it was an easy matter to overlook the oxyuris in the appendix if there were but one present. In searching for parasites the method which had been pursued was to open the appendix, wash out its contents with normal salt solution, centrifuge and examine the sediment under the microscope. In this way male oxyurides had in several instances been found in cases where they would otherwise have been overlooked.

Cirsoid Aneurysm.—Dr. Hugh Auchincloss said that this report was in reference to a case of clinically cirsoid aneurysm in which Dr. Blake excised the external carotid. The aneurysm was left untouched. Sections made of the external carotid showed the following suggestive findings: At various levels near that end of the excised artery distal to the aneurysm the intima and inner portion of the media were normal. Between the outer portion of the media and adventitia the muscle, elastic, and connective tissue fibers were separated by blood cells to a moderate degree. At levels nearer the aneurysm this hemorrhage was more marked and at one point high up the wall showed on one side an almost complete loss of muscular coat, fibrillation of the internal elastic lamina, and a few blood cells in the thinned wall which at that point was thrown up into a papillary-like fold. Two possibilities seemed preeminently evident. One, that the hemorrhage was caused by litigation of branches at time of operation. The second, that there had been a hemorrhage from the main auerysmal mass along the wall of the carotid. It was thought that the latter was perhaps more probable because the hemorrhage seemed in places to give evidence of longer duration than in others, although endothelial lined channels were not seen. Cirsoid aneurysms were rare. Theoretically, perhaps, they should be limited to that group of cases where one artery and its branches have become elongated, tortuous and branched, so that there may be said to be an arterial neoplasm of which the congenital is the rare type. Clinically and practically, however, they more often occurred as result of trauma, where a vessel or vessels, normal or already diseased, bled into the tissue spaces and formed cavernous, endothelial lined blood spaces which tended to spread. There had been and still was an idea that they spread centripetally, *i.e.*, toward the heart. W. G. MacCallum had emphasized sudden strain and the ease with which a sclerotic aorta might be split, as factors in dissecting aneurysms. In this instance the points of interest were: A clinically typical cirsoid aneurysm of the right temporal region, an elderly woman, diseased external carotid, trauma from a hatpin stuck into temporal region shortly before beginning of aneurysmal tumor, an aneurysm progressively increasing in size with more recent symptoms pointing toward internal maxillary involvment, and hemorrhage between adventitia and media of external carotid, the site where a dissecting aneurysm in an artery generally occurred. Traumatic cirsoid aneurysms had been reported by C. Beck in a case thirty-two years old, after being struck by a stone; Rushton Parker, in a case nineteen years old, after striking head on stone and gradual growth of tumor for fourteen years; Matas, in a case of fractured skull, eighteen years previously.

Dr. J. A. Blake said that the patient was sixty years of age, and that about a year and a half or two years ago she stuck a hat pin in the side of her head. No attention was paid to this until last summer, when a swelling appeared on the side of the head, and in October or November a physician in the town in which she lived opened it, thinking it was an abscess, and immediately there was a profuse hemorrhage, which was hard to stop. She had a visably pulsating tumor which occupied the whole right side of the scalp with an irregular surface, the highest portion being elevated about 2 cm. above the general contour of the parts. On palpation it evidently consisted of a mass of enlarged vessels, pulsating forcibly, and between the vessels hard, irregular, wall-like elevations could be felt; as if the vessels had produced channel-like excavations in the skull, of which these were the margins. The pulsation of the carotid at the zygoma showed plainly, and a distinct bruit could be heard down as far as the parotid region. He thought at the time that it was a cirsoid aneurysm, and considering what had been said about these having a tendency to extend toward the heart, he thought it best to excise the carotid artery, thus stopping the extension and at the same time cutting off the blood supply. This was done, the external carotid being excised from its origin to just below its bifurcation into the internal maxillary and temporal arteries. The pulsation disappeared at once and the mass has since shrunken away, leaving, however, the irregular elevations before referred to. The terminal portion of the excised vessel appeared dilated and thinned. Dr. Auchincloss' report upon the sections of the vessel was exceedingly interesting and suggestive. It strongly pointed to a traumatic origin of so-called cirsoid aneurysms. Other evidence in favor of this theory was the fact that the cirsoid aneurysms which had been reported had for the greater part occurred in the scalp where the arteries were particularly subject to injury against the unyielding cranium.

The Organization of a Hospital Staff.—Dr. Joseph A. Blake read this paper. (See page 1139.)

240th Regular Meeting, Held May 5, 1911.

The President, Dr. H. M. Biggs, in the Chair.

Organization of the University Hospital Staff.—By Dr. W. Gilman Thompson. (See page 1142.)

Dr. J. A. Blake said that while he had nothing to add to his paper he was very glad to learn that it had been put into practical application. As Dr. Thompson stated the only difference was that no resident house staff was included in the scheme. With such officers some of the duties which here were given to some of the adjunct assistant visiting physicians could be given to the residents. By this he did not mean that the residents were to take the place of the assistant visitings. The great advantage of having resident physicians and surgeons was that they lessened the responsibility of the rotating house staff, and he had found that this responsibility was entirely too great for a number of house surgeons to bear, and that the patients suffered on account of their lack of knowledge and skill. The resident physician was one who had been selected with care, and he might remain for years, and the advantage was that these men became very skilful and the public benefited too on account of their superior education when they left the hospital. The idea of associating one of the laboratory collaborators with each member of the staff the speaker said was a good one. The only apparent objection was that there was a possibility of frequent changes taking place in the subjects the visiting was interested in, and in that event there might be a need for as many changes in the person of the laboratory assistant.

Dr. C. L. Dana said that one of the points of interest in this system was the establishing of a series of clinical clerkships in neurology so that each student for two weeks in the afternoon worked in the hospital wards. He was assigned to cases, which he was to study, read about, fol-

low up, and then to write the history. This, the speaker thought, was going to become one of the best features in teaching neurology that had as yet been devised.

Dr. G. L. Peabody said that this was an enormous advance over the present system and that a large expense was incurred for its support. He made inquiry as to who was responsible for the duties formerly performed by the attending physician and who took the place of the attending physician in his absence.

Dr. L. A. Conner stated that in this scheme the neurologist visited cases throughout the year. The service at present consisted of 90 beds, which were divided into two divisions, each consisting of 45 beds. Dr. Meara, professor of therapeutics, was in charge of one and Dr. Coleman had supervision of the other, and they had assistants under them. They spent a part of each afternoon at the hospital and prescribed treatment for the patients.

Dr. Peabody asked if the assistant visiting prescribed for the patients, and who was actually responsible for the well-being of the patients.

Dr. Conner answered the inquiry to the effect that the visiting physicians were responsible, and that they came into daily contact with the patients.

Dr. Peabody then asked the former speaker if the adjunct and assistant physicians did not treat or prescribe.

Dr. Conner replied that they took up the work that had been assigned to them, and that they replaced the visitings when the latter could not come. There were five or six men in the ward every day.

Dr. Peabody said that it was certainly a very striking advance over the methods at present in operation, and the only difficulty that presented itself was the expense that was connected with it for its maintenance.

Dr. Conner replying said that it was the university professors only who were salaried; and certain of the adjuncts, who were teachers, also, received a salary as teachers.

Dr. W. M. Polk said that this situation from the standpoint of the hospital was that they were able to say to the board of trustees that this patient received the same treatment, care, and attention as he would in the richest man's house in New York City or in any private hospital or sanatorium. Each individual case was worked up by a student assigned who had to investigate it according to modern methods. Men were assigned to work alongside of him, who of course had to be paid. The patient was therefore looked upon as a first consultation because it was considered to be the best way to appeal to the student. He did not hesitate to say that by such means the people also were being educated The workers in the wards were divided into the actual visitings, who were responsible to the board of trustees, and who had under them certain men who were there for the purpose of aiding to keep up the care of patients, teaching, and discipline. These latter were known as assistant visitings and adjuncts. The work of the student was divided into ordinary physical examinations and history taking in the wards and laboratory work. Those men who were called assistant visitings went around from bed to bed and saw that the students were attending to their business and putting their minds on their work, and hence they were at hand to answer any questions asked of them. They devoted their entire day. The laboratory workers were of two kinds: ordinary clinical pathologists, who were to do the routine investigating work for the patients and aid the students, and those assigned to help the students in their work viz., the assistant visitings. This involved at all times a regular attendant in the laboratory alongside of the ward (which will be transferred to the large laboratory when it is erected). The more advanced of this group of men, the speaker said, would come in and do the Wassermann and Widal tests and serum work, so that this branch of the service was covered by men who were expert in that line, the idea being not to allow any man to be obstructed in his work of inquiry. A second group did advanced research work on problems set by the visiting physicians and surgeons. There were to be two or more side workers as attendants on the visitings. The situation, Dr. Polk said, was one that had a great deal of promise in it. In addition to the above the speaker said that it would be necessary to have special nurses who were well trained, as others not so skilful were apt to lose specimens of feces and urine in cases, and hence retard and upset laboratory tests and nullify all. At first they were a little afraid of the board of trustees, but they said that what was worth doing at all was worth doing well, and he proved to them that this was the right method for the handling of patients and that it was not an exploitation for the benefit of any education school. He said that if they had had an ununited board of trustees they would not have accomplished anything, but that they were fortunate in having a liberal minded board who had helped them along in establishing this method.

Dr. Gorham Bacon asked if it was intended to provide for special branches such as the ear, eye, etc., and was the same plan to be carried out in reference to these subjects.

Dr. Blake replied to Dr. Bacon's question by stating that it was to apply to all specialties, but not as extensively to some as to others. The term surgery was used as an illustration.

Dr. W. M. Polk said that he did not think that the men could give their entire day, and therefore it had been arranged that they would come for a part of the day and that they would alternate. Men would be assigned each day to attend to the cases when they were being treated and when they were being operated on, and in this way the students would learn the care of patients much better than when they had their hands in, and they could better ask questions, consequently learning more by looking on than in assisting in the operations.

Dr. Bacon then said that the education of the house staff would depend upon the generosity of the visiting surgeons, and that consequently the house staff would not be able to get as many operations and therefore not as much experience as it did under the present system.

Dr. Peabody replied that they would really learn a great deal more than in the old way.

Dr. J. A. Blake said that for two years he had had in operation the scheme in reference to the clinical clerks, and that it had not interfered with the house staff. They examined the patients and made diagnoses under a supervisor, and they followed the patient to the operating room, asked questions, got the material that was removed from the patient, which they took to the laboratory for examination. The house staff had expressed themselves as having been benefited by this arrangement because the instruction was of a higher type and that all the time they were absorbing more than they otherwise would.

Dr. G. Bacon asked if this scheme caused any clash between the assistant visitings and the house staff.

Dr. Polk answered the question by stating that the assisting visitings were there on account of the students and that the house staff were there to take care of the patients. The patients got better attention, and a certain amount of each student's time was taken up in reading up on the subject under his care. He said that the use of the alcoholic, psychopathic, and convalescent wards was one of the widest value for the neurological student found anywhere.

Dr. Conner, speaking of the clinical clerkships, said that the success or failure of the system depended almost entirely upon whether or not the student-clerks were carefully supervised and taught during their work. Without such constant supervision and teaching there was sure to be much waste of time and the system was of doubtful

value. As regards the question of a permanent resident house staff Dr. Conner thought that one serious difficulty with the rotating staff was the fact that the men often lacked the experience and training necessary to enable them to make and record accurate observations upon the patients so that the hospital histories and records suffered The third point the speaker made reference to was the constitution of the Medical Board. Dr. Blake's suggestion that the board include the superintendent of the hospital was a new idea to him, but one that seemed to him worthy of serious consideration.

Dr. Dana said that the medical director was the superintendent, and that he had as an assistant one who was a sort of steward [illegible] ctor was a trained physician, who was responsible for the [illegible] l care of the patients; he was a memb of the [illegible] ...emical board as were also the two laboratory men.

Dr. W. M. Polk thought that the director should have a consultation practice and that he should do outside work so that the people would have the benefit of his special knowledge.

Dr Conner thought that if it could be arranged to permit the director to have office arrangements to see patients in consultation he could then concentrate all his working day at the hospital.

Dr. Polk further said that he should then be given a large salary so that he could devote all his time, rather than be given some consultation hour or 10 beds as that would take up his time from his hospital work. But to protect him he should be given time to come in contact with the outside profession so that he would become a practical man and in order that his skill might benefit the community. He was in favor of giving him a definite time at the hospital and then a certain amount of time to himself to do what he wished.

Dr. Winford H. Smith, General Medical Superintendent of Bellevue and Allied Hospitals, said that he had been trained under such a system, one providing residents and clinical clerks. He said that the time the students spent as clinical clerks was worth more to them than any other feature of their medical course. The house staff serving under trained residents really got more out of an internship than under the system where the members of the house staff were left alone at their work the greater part of the day to pick out whatever experience might be possible, and under the resident system their work was better supervised and the features of each case presented to them in better form. An interneship under residents was much better, the speaker said, for the reason that the training was obtained under men who had been in the hospital from two to four years or more. It was impossible for the staff to get many hours of instruction and supervision from a visiting staff, and it was particularly difficult if the visiting staff was organized on the basis of a rotating service. From the standpoint of the administrator this system was also a benefit to the hospital. It was somewhat more expensive, as it added to the payroll, but the amount represented by salaries for the residents was made up to some extent by the fact that there was better supervision of the work. The work was more carefully carried on, with the result that there was greater economy in the use of supplies and in the running of the wards. In the assignment of clinical clerks it was essential from the hospital standpoint that there were not too many on duty to interfere with the hospital work, and that they work under definite instructions, proper supervision, and within prescribed hours; otherwise the hospital work was hampered. It was true that in a teaching hospital where the clinical clerk system was used more nurses were needed, because of the more detailed attention required for the ward work. Speaking of the general hospital situation, Dr. Smith said that the hospital which had the advantage of teaching within its wards was the better hospital, for each case was studied with greater care by the visitings in order that the case might be properly presented to the students; and the more careful the study of each individual case, the more care and attention was given to taking proper records, and to maintaining proper standards in all respects; all resulted in benefit to the patient, and this, from the standpoint of the hospital itself, was what was most desirable. As a general statement it might be said that the hospital was fortunate which had the advantage of teaching carried on within its wards. The system outlined by Dr. Blake and Dr. Thompson, possibly with the elimination of certain features applicable only to a university hospital, would apply to any general hospital, and would appear to be the best form of medical organization for any general hospital, certainly the best for the university hospital, because it provided a continuous service as against the old antiquated form of hospital organization, the rotating service. Under the continuous service system a definite policy was followed throughout the year. The same men were engaged in the study and care of the patients throughout the year, while under the rotating service there was no definite general policy followed There were as many different policies as there were different men, and one set of visitings came on the service and no sooner got in full swing than it was time for them to leave and another set to come on. Also, under the rotating service, there were so many different men with different policies whose whims had to be catered to that it was an exceedingly expensive system from the administrative standpoint.

Medicolegal Notes.

Action for Services—Employment to Attend Another.—In an action by a physician for his services the plaintiff testified that the defendant employed him to attend her mother and that the defendant at the time of employment agreed to pay him for his services, and that she had paid him a sum on account as the result of a letter sent by him to her demanding payment. The defendant denied the employment by her or that she paid any sum on account. Her employee testified that the defendant's mother sent him to the plaintiff with a bill and money in an envelope; that the plaintiff took out the money, receipted the bill, and the witness took the receipt to defendant's mother. The court reversed a judgment for the defendant as against the weight of the evidence. The plaintiff had produced a letter from defendant which he said was in reply to a letter requesting payment. The defendant said the letter was a forgery. A comparison of the signature to the letter with admittedly genuine signatures of the defendant left little doubt in the court's mind of the genuineness of the signature. No reason was suggested or apparent why the defendant's mother, or any other person, should forge the letter.—Kamenoff v. Gammon, New York Appellate Term, 127 N. Y. Supp., 226.

Court's Jurisdiction to Try Question of Applicant's Competency after Refusal of License by State Board.—An application for a license to practise medicine and surgery in the State of Washington was filed with the Board of Medical Examiners in that State under Laws 1909, C. 192, and after examination, refused. The applicant appealed to the Superior Court for the county, which directed the issuance of the license, and this was affirmed on appeal. It was held that under section 13 of the statute providing for an appeal from a denial of the application to the Superior Court, that court had jurisdiction to hear the merits of the case on trial *de novo* and itself administer the provisions of the act. The question at issue was whether the applicant had earned a rating equal to 60 per cent. on the subjects of histology, pathology, and general diagnosis, which he was required to obtain under the statute before a license could issue to him.—*In re* Littlefield, Washington Supreme Court, 112 Pac., 234.

No Remedy to Compel Issuance of License after Expiring of Time of Appeal from Board's Decision.—After the right of appeal given by the Washington statute (Laws 1909, C. 192), which must be taken within thirty days after the filing of the decision of the board, has ex-

pired, the applicant cannot, it is held, obtain relief by mandamus against the Board of Examiners to compel the issuance of a license. He had an adequate remedy by appeal which was not affected by his failure to avail himself of it within the statutory period, therefore his contention that he had no remedy by appeal remaining to him was not sustained.—State v. State Board of Medical Examiners, Washington Supreme Court, 112 Pac., 746.

Construction of Idaho Laws as to Issuance of Licenses to Practice.—An application for a writ of mandamus was made against the State Board of Medical Examiners of Idaho to compel the issuance of a license to practise medicine to the applicant, who was a duly licensed graduate of the Western University of Chicago and Independent Medical College of Chicago, and had complied with the provisions of the Idaho statutes as to practising. Under the provisions of section 1298, Idaho Rev. St., 1887, no person was permitted to practise medicine or surgery in the territory who had not received a medical education and a diploma from some regularly chartered medical school having a bona fide existence at the time the diploma was granted. It appeared from the applicant's complaint that he was engaged in the practice of his profession under the provisions of that law, and had complied with the provisions of section 5 of the Act of 1899 (Sess. Laws, p. 346.) It was held to be the duty of the board to issue to him a license. The board had no authority to refuse a license on the ground that the college issuing his medical diploma was not a "reputable college of medicine in good standing," as the law of 1887 provides for a diploma from some "regularly chartered medical school." There being no provision for appeal in the Idaho medical law of 1899, the applicant had no adequate remedy at law by appeal, and was entitled to mandamus.—Vadney v. State Board of Medical Examiners, Idaho Supreme Court, 112 Pac., 1046.

Elements of Damage for Negligent Treatment—Effect of Disposing of Real Estate after Filing of Suit.—In an action against a physician for negligent treatment it was alleged that the plaintiff's broken wrist had been permitted to remain out of place so long that it could not be properly set or cured. It was held that while the personal disfigurement resulting from the injury was an element of damage, and, also, the mental distress reasonably occasioned by it, the worry and mental pain resulting from the contemplation of the deformity and the humiliation of going through life in that condition were too remote to be considered as damages.

The fact that after the suit was filed the defendant conveyed his real estate to his wife was held to be competent evidence as tending to show a feeling that he might not have properly treated the plaintiff, but he was entitled to explain the transaction.—Harrod v. Bisson, Indiana Appellate Court, 93 N. E., 1093.

Dissection—Assent of Relatives or Friends—Construction of Phrase.—Under Section 2213 of the New York Penal Law (Consol. Laws, C. 40) dissection of a human body may be performed with the consent of the husband, wife, or next of kin. This is extended by section 316 of the Public Health Law (Consol. Laws, C. 45) so as to permit hospitals to deliver corpses to medical colleges with the assent of "relatives or friends." Construing this provision, it is held that the consent of relatives must be obtained if they can be found, and that reasonable inquiry must be made to find them. Only in case they cannot be found will the assent of "friends" suffice. Where no effort to find the relatives of the deceased is shown to have been made, beyond the fact that the name of a woman was entered in the hospital records as "friend," it was held that this was not a compliance with the law.—Newman v. Stewart, 127 N. Y. Supp., 866.

Action for Libel by Osteopath.—An osteopathic physician claimed damages for libel from the physicians and dentists occupying offices in the building where he maintained his office, they having inserted an advertisement in a local newspaper classing him as a quack and charlatan. It appeared that he had his name upon his office door preceded by the letters "Dr." and followed by the words "Osteopathic Physician," in violation of the Washington Laws, 1901, section 3, p. 50. It was held that he could not maintain such an action for libel, his practice being founded on a breach of the law, and the law would afford him no redress for the loss of earnings sought to be acquired in that manner. Nor could he show that he had a common-law right to practice osteopathy without a license, and that he was libeled while pursuing that right. If he had advertised and practised as an osteopath, that question would have been presented.—Lathrop v. Sundberg, Washington Supreme Court, 113 Pac., 574.

Medical Items.

Retroplacentar Hemorrhage.—P. Lequeux describes a case of retroplacentar hemorrhage observed by him. In this complication there is suddenly every appearance of internal hemorrhage, without any flowing at first. Later the hemorrhage appears externally. Unless delivery is rapidly effected the patient dies in collapse. In the treatment of such a case whenever it is possible to deliver the patient without the use of the knife it should be done. But with a rigid, undilated cervix and no labor pains this is impossible. If the patient is infected, the ovum open, or hemorrhage be of ancient date the vaginal cesarean section should be preferred. If she is not infected and shock is not too great, with this was the case and recent hemorrhage, the abdominal cesarean section is to be used. If in the classical operation we do not fear secondary hemorrhage and there is no fear of a latent infection hysterectomy will not be necessary. But with danger of infection or secondary hemorrhage a Porro operation is justified.—*Bulletin de la Société d'Obstetrique de Paris.*

Calcium and Spasmophilia.—J. Rosenstern notes the relationship between calcium deficiency and spasmophilia. The administration of calcium chloride to spasmophilic children causes a reduction of the electrical excitability and disappearance of the convulsive manifestations.—*Jahrbuch für Kinderheilkunde.*

Health Reports.—The following cases of and deaths from smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended June 16, 1911.

A.

Abbe, R., resection of the posterior roots of spinal nerves to relieve pain, pain reflex, athetosis and spastic paralysis—Dana's operation, 378.

Abbe, T., two cases of ainhum, 478.

Abdomen, acute, rare causes of, 166; acute conditions of and pulmonary conditions, 975; arrested development of wall of, 597; contusions of, 606; emergencies in acute disease of, 736; surgical anatomy of wall of, 13; tenderness of, with pain due to thoracic lesions, 1072; upper, surgery of, 163; viscera of developmental defects in, 745; wounds of, gastric weak line in, 1023.

Abortion, criminal, 1092, 1121; legal and religious aspects of, 480; prevention of, 31; septic, irrigation in, 596

Abscess, appendix, rectal drainage of, 1111; hepatic, 794; ischeorectal, melted iodoform ointment in, 340; of wall of stomach, 787; pulmonary, 793; splenic, 263; subphrenic, 231, 410.

Acari, and tumor formation, 507.

Accidents, industrial, 77.

Acetone, in inoperable uterine cancer, 1110.

Acid, intoxication, postanesthetic, 501.

Acidosis, and phosphorus poisoning, 167.

Acne rosacea and keratitis, 204.

Acromegaly, 72; eye symptoms in, 405; from fright, 694; skeletal changes in, 829.

Addison's disease, a case of, 1145; and status lymphaticus, 126.

Adenoids and enlarged tonsils, necessity of removal of, 903; and tonsil operations, 545; and tonsils, removal of with the aid of mental suggestion instead of anesthetics, 1004.

Adrenalin, in peritonitis, 1113; forms of action of, 321.

Adrenals, see suprarenal capsules.

Ainhum, two cases of, 478.

Air, liquid, and carbonic acid snow, 31, 162.

Alaska, sanitary conditions in, 915.

Albumin, assimilation of, 506; in tuberculous sputum, 878; reaction in the sputum, 456; simple test for, 506.

Albuminuria, adolescent, after-history of, 969; and cylinduria, mineral water cures in, 589; cyclic, 1012; differential diagnosis of, 506; orthostatic, in tuberculosis, 1019.

Alcohol, and insanity, 964; beverages of, comparative toxicity of, 1073; in the tropics, 343; mental defects following use of, 158; methyl, amblyopia, due to, 1065.

Alcoholism, 247; and morphinism, 971; and phthisis, 441; influence of on offspring, 216; medical problems of, 260; parental and offspring, 223; influence of parental on offspring, 221; phychoses of, pupils in, 972, see inebriety; significance of history of, 770.

Aleppo-boil, see Oriental sore.

Alimentary canal, sensibility of in health and disease, 881, 919, 925, 973; stones in, 1022; *x*-ray examination of, 1024.

Alopecia, nervous factor in, 1058.

Amebæ, in human intestine, comparative study of, 732.

Amebiasis, in New York, 219.

Amputation, major, safeguards after, 585.

Analgesia, spinal versus spinal anesthesia, 585.

Anaphylaxis, 501; a case of, 356; and asthma, 218; and eosinophilia, 122; and infectious diseases, 502; cellular, 1020; of gastric juice, 608.

Anatomy, visceral teaching of, 1066; who loves, 490.

Anemia, pernicious, 1075; pernicious family, 924; pernicious, secondary, 978; pernicious, transfusion of blood in, 239; pernicious, salvarsan in, 599, 877; pernicious treatment, 1069; splenic, treatment of, 78; splenic resembling Hodgkin's disease, 981; Widal reaction in fatal case of, 79.

Anencephalus, 973.

Anesthesia, 924; death from gas and oxygen, 257; ethyl chloride, 33, 224; general, combined with narcotics, 830; in labor, 1159; intravenous, 832; in traumatic surgery, 33; insufflation, 783, intranasal, in extraction of teeth, 1055; local, syringe for, in rectal surgery, 315; local, with quinine and urea hydrochloride, 697; nitrous oxide, 412; nitrous oxide and oxygen, 33; pantopon, 413; reform movement in, 1157; scopolamin—morphine in, 319; spinal, 688.

Aneurysm, 227; circoid, 1163; external plantar, 692; of aortic arch, 1014; of aorta, 88; of innonimate artery, 974.

Angina pectoris, abnormal breathing in, 1016.

Angioma, radiotherapy in, 723; of brain, extirpation of, 926.

Ankle, tuberculosis of, 1155.

Ankylostoma, 779; infection, 550, 639, 692, 735.

Anorectal diseases, 637.

Anteflexion, treatment of, 226.

Anthrax, internal, 736.

Anthropology, of ancient British races, 640.

Antibody formation identical with cell degeneration, 832.

Anti-enzyme, formation and intoxications, 890.

Antipyrin, supersensitiveness to, transmitted to guinea-pigs, 268.

Antiseptics, new principle in action of, 275.

Antitoxin, diphtheria, death following, 734.

Antitryptic reaction in pregnancy, 1006.

Antivaccination, 408; revival, 113.

Antivaccinationists in Berlin, 731.

Antivivisection, 73; bill, Bayne, 726.

Antivivisectionists, 400, 786.

Aorta, aneurysm of arch of, 1014; aneurysm of descending arch of, 85; dilatation of, due to constriction at the isthmus, 652; insufficiency of, work of heart in, 1117; shot through, 127.

Aphasia, 640; congenital, 1017; pseudo-, hysterical, 1020; study, fifty years of, 883.

Appendectomy, technique, 452; with cocaine analgesia, 250.

Appendicitis, acute suppurative, 274, 504; and American-made flour, 819; and its moving pathology, 386; distribution of, 125; colicky pains of, 915; chronic, 748; hemorrhagic, 268; hidden dangers of, 1017; in childhood, 32; oxyuris, 1162; treatment of, with high frequency currents, 54.

Appendix, abscess, rectal, drainage of, 1111; abscess, treatment of, 693; and omentum, gangrene of, 123; disease of, and duodenal ulcer, 222; dyspepsia due to, 974; fistula between, and gall bladder, 737; infantile, pinworms and caraway seed in, 596; inflammation of, see appendicitis; intussusception of, 549; lesions of, 1067; primary carcinoma of, 34; sarcoma of, 121; two in one person, 221.

Apraxia, neurology of, 1109.

Army camps, sanitation of, 539; maneuvers, medical side of the, 941.

Arnold, W. F., prophylaxis against hookworm infection by means of efficient shoes, 534.

Arrhythmia, of heart, 88, 266; unusual case of, 651.

Arsenic, antihemolytic action of, 267; in syphilis, 453.

Arteries, rigidity of, in childhood, 359.

Arteriosclerosis, 744; and the kidney, 836, 883; myalgia in, 726; precocious, psychic causation of, 1008; premature, psychic etiology and treatment of, 879.

Arthritis, chronic, 74; deformans, relation to intestinal putrefaction, 579, 603; deformans, surgical treatment, 603; rheumatoid, 599; rheumatoid and oral disease, 780; rheumatoid and diseases of the mouth, 598; rheumatoid, vaccines in, 1017; tuberculosis, 1157.
Ascaris lumbricoides, infection of the liver, 733.
Ascites, clinical study of, 1071; in hepatic cirrhosis, 359; lymphangioplasty for, 882; pseudochylous, 1118.
Asepsis, ultra-rigid among teachers, 488.
Asphyxia of new-born relieved by placental aeration, 250.
Aspiration, device for, 262.
Aspirin, idiosyncrasy to, 263, 881.
Asthenia universalis congenita, 972.
Asthenopia, phases of, 219.
Asthma and anaphylaxis, 218.
Ataxia, Friedreich's, 85.
Atlee, E., uterine cancer and its early diagnosis, 897.
Atrophy thenar, 881.
Audiometer, improvement in, 303.
Auricle, fibrillation of, 802.
Auscultation of cough, 746; of joints, 318; sounds, postmortem, 170.
Austin, C. K., a case of multiple myeloma with albumosuria, 761.
Australia, sanitation in, 1013, 1063.
Autoinoculation, rôle of, 318.
Automobile, favorable effects of, on nervous disorders, 1149.
Autoserotherapy in chronic pleurisy with effusion, 650.
Autopsy, importance of, 546.

B.

Bacillus, carrier in spread of cholera, 218; colon, in cerebrospinal fluid, 1018; colon, in urine, 546; diphtheria, virulence of, 597; gas, causing diarrhea, 504; tubercle, identification of, 164; tubercle, in tuberculous meningitis, 133; tubercle, non-occurrence in human sputum, 508.
Backache, chronic, 827.
Bacteria, cinematography of, 635; examination of blood for, 87; in gastrointestinal disease, 925; persistence of in body, 925; stain for capsule of, 306; variation among, 35.
Bacterins, see vaccines.
Balantidium infection, studies of, 733.
Balneology, in treatment of disease, 1158.
Bandage, simple head, 690.
Bangs, L. B., bilateral nephrolithiasis, left nephrotomy, 394.
Banti's disease, a case of, 1022; cured by salvarsan, 695.
Barnes, F. H., treatment of neurasthenia, 959.
Barnes, W. S., ichthyol in pulmonary diseases, 109.
Bartlett, C. J., a vaccine shaker, 562.
Bartlett, W. A., mistakes in the diagnoses of chronic lesions, 847.
Baruch, S., Holmes and Semmelweis, 214.
Bashore, H. B., Pennsylvania's work in rural sanitation, 1146.
Baths, floating pollution of by sewage, 1039.
Beer, E., direct inspection of the rectum and sigmoid colon, 243.
Belching, causation of, 1000.
Bell, Charles, Sir, among anatomists, 356.
Bell, G. H., ocular manifestations of the peripheral affections of the fifth cranial nerve, 863.
Belladonna poisoning, acute psychosis due to, 1050, 1154.
Benedict, A. L., gastric röntgenology, 348.
Benzidin test for occult blood in gastrointestinal diseases, 1026.
Benzol, poisoning, acute, 1158.
Berg, H. W., posture as an aid in the diagnosis and treatment of cardiac affections and dropsical conditions of various origin, 609.
Beriberi, 216, 636; among Philippine native scouts, 1058; and polished rice, 312, 689; eradication of, 689; etiology, 34; experimental and rice, 690; infantile, 689; relation of poliomyelitis to, 1095
Berlin Medical Society, 119.
Berliner, E., an auto-aseptic thermometer case, 513.
Betts, J. B., a case of aneurysm of the heart, 335.
Bier's clinic, in Berlin, a morning at, 462.
Bile, bacteriology of, 972; duct, common, catheterization of, 228; ducts, lithiasis of, 500; ducts, congenital atresia of, 817; passages, surgery of, 101.
Bilharzia, affection of bladder, 352; infection, 30.
Birth rate, decline in, 22, 439, 881, 965.
Bishop, L. F., fibrillation of the auricle, 802; the Nauheim methods in the management of cardiac disease, 531.
Bismuth, in gastric therapy, 635.
Bladder, and kidney stone, 224; and prostate, 742; best method of exposing for operations by suprapubic route, 174; bilharzia affection of, 352; calculus of, 634; calculus of, following pubiotomy, 1118; carcinoma of, 1065; catheter in, 450; operations for stone in, 454; papilloma of, removed by high frequency current, 605; paralysis of, 547; penicillium infection of, 637; rupture of, medical expert testimony as to, 607; section of, see cystotomy; tabetic, 75, 121; tumors of, 409; tumors of, intravesical operations for, 409; tumors of, operations for, 409; tumors of, treated with high-frequency current, 741; tumors of, modern treatment of, 680; *x*-ray examination of, 264.
Blake, J. A., some observations on the organization of hospital staffs, 1139.
Blastomycosis, systemic, 785.
Bleeding, or saline infusion, 678.
Blistering, extensive, in an infant due to scurvy, 736.
Blood, bacterial examination of, 87; corpuscles, coloring matter of, 127; entrance of germs into, prognostic significance of, 457; fixing of stains of, 78; flow of, effect of hydrotherapy on, 1117; in diseases of the nervous system, 1076; pipettes, case for, 547; platelets, 1016; pressure, clinical value of studies, 207; pressure, effect of cold air on, in respiratory affections, 180; pressure, effect of hypophysis on, 1075; pressure, high, 745; pressure, high, and kidneys and adenals, 787; pressure, low, 775; pressure, measurement of, 314; pressure, psychogenetic instability of, 81; stain, detection of, 497; direct transfusion of, 198; transfusion of, 123; 691; transfusion of defibrinated, 127; *x*-bodies in, 357.
Bones, and joints, skiagraphy in the surgery of, 552; long, acute inflammation of, 1109; needling of, test of malignancy, 584; overgrowth of epiphysis of, 354; spontaneous fracture of, 1112.
Bonesetting, 1113.

Dawbarn, R. H. M., short talks with my students and others; being random suggestions for the younger practitioners, 395, 488, 584, 677, 771, 869.
Deaf, education of, 506.
Deafness, common forms of, 830.
Death, international list of causes of, 1101; rates in Japanese war, 618.
Degeneracy, 30.
Degeneration, race and eugenics, 1007.
Delinquents, mentally defective, and the law, 464.
Dementia precox and pupillary disturbances, 81.
Dengue, virus of, 451.
Depression, etiology of, 1069.
Dermatitis, aphthous, 416; chemical, 973; toxic, 35.
Dermatologists, 351.
Desiccation, electrical, 1156.
Desmoid tumors, of abdominal wall, 271.
Diabetes, and oxaluria, 155; and tumor formation, 210; classification of, 1154; gout and cystinuria, chemical relationship of, 835; infantile, 29; insipidus, 549; lipemia in, 81; lipogenous, 738; mellitus in a child, 342; mellitus, specific treatment for, 1075; mellitus, treatment of, 717; of pregnancy, 927; pancreas and, 543; potatoes in, 877; stomach in, 411; transmissible, 360; youthful, 43.
Diagnosis, nose and throat in, 409; of chronic lesions, mistakes in, 847.
Diarrhea, due to gas bacillus, 507; infantile, 548; infectious, 504; infectious, silver nitrate irrigations in, 504; see dysentery.
Diastases in urine, 1069.
Diathesis, and dyscarsia as viewed today, 831; oxypathic, 156.
Diazo reaction, new, 352; source of error in, 581, 1106.
Dickinson, G. K., appendicitis and its moving pathology, 386.
Diet, excessive, consequences of, 964; high caloric, in typhoid fever, absorption of fat in, 181; in childhood, 164; in typhoid fever, 314; menus for high caloric, 181; popular hygiene of, 1020; restricted in diseases of the skin, 139.
Digitalin in heart disease, 507.
Diphtheria, abdominal, 221; abnormal cases of, 276; active minimization against, 818; and public health, 124; antitoxin, death following, 734; antitoxin, untoward effects of, 15; bacilli, virulence of, 597; carriers, 693; carriers in spread of, 1043; carriers, pyocyanase for, 695; gangrene of leg following, 808; gangrene in, 222; high death rate from, in the United States, 568; laryngeal, intubation in, 1160; of conjunctiva, 1016; of vulva, 122; serum treatment of, 414.
Disease, and mutation theory, 21; and weeds, 963; chronic, mistakes in diagnosis of, 847; controlled by hypodermic use of aseptic chemical solutions, 365; simulated, 455.
Disinfectants, standardizing of, 1148.
Disinfection of plague ships, 440.
Dislocation of knee, 319.
Dispensary abuse, 629.
Dissection, assent of relatives for, 1166; dry gauze sponge, 397.
Documents, pathological, from antiquity, 725.

Doty, Dr. Alvah H., as health officer of the port of New York, 726.
Diuretic, choice of, 414.
Drainage, suction, 701.
Dreams in etiology, 972.
Dropsy, cardiac, excretion of chlorides in, 268.
Drugs, abuses relating to, and the law, 786; addiction to, treatment, 412; absorption of, 1034; injection of into lumbar muscles, 515.
Duodenitis, 62.
Duodenojejunostomy, 597.
Duodenum, function of, 1024; lavage of, 261; ulcer of, 27, 158, 164, 596, 649, 733, 784, 1024; ulcer of, and appendicular disease, 222; ulcer of, cause and relief of pain in, 1024; ulcer of, diagnosis, 720; ulcer of, diagnosis and surgical indications, 741; ulcers of, hyperchlorhydria and pyloric obstruction due to cancer developing in, 1025; ulcer of, perforation in, 1025; ulcer of, treatment, 34, 158.
Dwarfism, 126.
Dysentery, bacillary, 503; bacillary, associated flora of, 504; Flexner, transmission of, 127; ipecac treatment of, 732.
Dyskinesia, intermittent, of arm, 1018.
Dysmenorrhea, 786.
Dyspepsia, appendicular, 974.
Dyspnea, tobacco, 1157.
Dystocia, cesarean section for, 319.

E.

Ear, action of salvarsan on, 883; disease of, 31; exostoses of external canal of, 83; foreign bodies in, in the insane, 232; meatus of, exostoses of, 1066; reflexes and, 313; reflexes referable to, 368.
Eaton, C. A., the vaccine treatment of typhoid fever, 797.
Echinococcus, specific reaction for, 501.
Eclampsia, puerperal, 318; puerperal and venom poisoning, 319; puerperal treatment of, 165; Stroganoff's treatment of, 360; treatment of, 564; with multiple pregnancy, 342.
Ecroyd, H., hydrogen in the treatment of whooping cough, 633.
Edehohls's operation in chronic nephritis in children, 1074; in treatment of chronic Bright's disease, 1074.
Edema, after salvarsan, 316; common salt and, 218.
Education, medical, 344, 556, 734, 1066; medical (president's address), 740, 1071; medical, conference on, 510; medical, curriculum preparatory to, 511; medical, equipment and instruction of the laboratory years, 510; medical, five-year course in, 510; medical, higher legislation in the interest of, 680; medical, instruction and equipment of the clinical years, 510; medical, progress and needs in, 510; medical, some evils in present system of, 556; medical, State control of, 556; sexual, 776.
Eggs, 75.
Egypt, climatic indications of, in otolaryngology, 436.
Einhorn, M., on pylorospasm, 97; stretching of the pylorus in benign stenosis, 1035; the importance of the thread impregnation test for the recognition of ulcers of the upper digestive tract, 475.
Eising, E. H., bilateral fibromyoma of the broad ligament, 532.
Electricity in chronic disorders of stomach, 103; in neurasthenia, 455; injuries caused by, 413.
Electrocardiograms, 230; and their significance, 189.
Elephantiasis, sporadic, 1075.
Embolism and thrombosis of the pulmonary artery, 673.
Embolism, cerebral fat, 882; fat, experimental, 585.
Emotion and action, clinical aspects of, 413.
Emphysema, pulmonary, and operative method of Freund, 251.
Empiricism, rational, and scientific medicine, 1112.
Empyema, bilateral, 1006; necessitatis, 924; physical signs of, 231; pneumococcus, prevention of by urotropin, 1074.
Endoaneurysmorrhaphy, 828.
Endocarditis, acute septic, 980.
Endometritis, septic, 261; vaginal hysterectomy for, 1068.
Endothelioma of pleura, 695.
Enema, electric, 692.
Enteritis, from *Trichocephalus dispar*, 547.
Enteroptosis, in children, 76.
Enuresis, nocturna, treatment of, 1018.
Enzymes in the urine, 820.
Eosinophilia and anaphylaxis, 122; familial, 1158.
Epididymitis, acute gonorrheal, 1003; gonorrheal, surgical treatment, 314.
Epiphysis, overgrowth of, 354.
Epistaxis, prolonged, 504.
Epithelioma, etiology, 77.
Erysipelas, Hiss extract of leucocytes in, 929; in babies, 984; magnesium sulphate in, 357.
Erythema, and joint lesions, 1112; multiforme as early manifestation of tuberculous meningitis, 180; primary *x*-ray, 695.
Erythremia, with unusual features, 620.
Eskimo, medical state of, 406.
Esophagoscopy for sharp foreign bodies, 505.
Esophagus, cancer of, excision of, 169; diverticulum of, 605; malignant disease of, 542; rare diseases of, 826.
Ether administration, the A—B—C of, 811.
Ethyl chloride, narcosis, 224.
Eucalyptus oil poisoning, 455.
Eugenics and race degeneration, 1007.
Evans, M. H., light from another angle regarding the analysis of thirty-two thousand cases of scarlet fever, 309.
Evans, W. A., ventilation of kitchens and bakeries, 12.
Exanthemata, 1112.
Exercise, rise of temperature after, 1017.
Excitement, clinical aspects of, 693.
Exhumation and dissection of body not permitted in accident cases, 607.
Exophthalmic goiter, 27, 828; and iodine, 599; and thyroid grafting, 80; and tonsils, 31; serum treatment of, 263; surgical treatment, 746; treatment of, 872.
Exophthalmos, pulsating, 1066.
Exostoses of auditory meatus, 83, 1066.
Experimentation, animal, and obstetrics, 827; animal and syphilis, 881.
Expert, medical, 874; medical, not an expert in insurance law, 513; medical, testimony as to cause of rupture of bladder, 607; medical, witness fees, 607.
Extension apparatus for applying plaster spica, 699
Eye, acuity of and rifle shooting, 689; adjustments of, 734, 972; and chronic spasms, 261; and facial expression, 1014; choked disc of and sarcoma of brain, 973; conditions of in medical cases, 258, 882; in sport, 80; nervous affections in relation to, 121; pregnancy and diseases of, 1110; strain of, 33; strain of in relation to health, 404; strain of reflexes dependent on, 367; wound of, 78.

F.

Fallopian tubes, absence of and menstruation, 319.
Fats, absorption of, in typhoid patients on high caloric diet, 181; and lipoids in tissues, 354, 734.
Faught, F. A., an improvement in audiometers, 303; the clinical value of blood pressure studies, 207.
Feces, typhoid bacillus in, 1148.
Feeding, artificial, history of, 780; infant, supplemental, 315; infant, fats in, 316; infant, insufficient, 268.
Felon, nature of, 585.
Femur, benign tumor of with fracture, 793; measure of shortening of, 677; spontaneous fracture of in tuberculous coxitis, 641.
Fernandez, F. M., the distribution of trachoma in Cuba, with notes in regard to a new procedure in treatment, 1098.
Fetus, intrauterine respiratory movements of, 1020.
Fever, after operations, 584; gastric, 492; in malignancy of kidneys and suprarenal bodies, 224; nature and significance, 1075; premenstrual, 880.
Fibrillation of auricle, 802.
Fibromyositis nodular, 265.
Fibroids, see myoma, uterus.
Fibromyoma, of broad ligament, 532; see uterus.
Fibrosis, chronic subcutaneous, 454.
Filariasis, surgical aspects of, 142.
Finger nails as evidences of recent severe illness, 820.
Finlay, Dr., and the yellow fever mosquito, 724.
Fistula, between gall bladder and appendix, 737; in ano, treatment, 545; pathology and treatment, 975; tract of, easy method of diagnosing and following, 996.
Flagg, P. J., the A—B—C of ether administration, 811.
Flour and appendicitis, 819.
Food and feeding, 1112; dirt in, 824; exposure of prohibited, 874; see diet.
Football, evils of, 18.
Footbrace, adjustable, for patients sitting up in bed, 835.
Foot, troubles of, diagnosis, 315.
Foreign body, bronchoscopy for, 200; in ear of insane, 232; in vagina, 349; metallic, in tissues, a new telephonic searcher, 671; sharp, esophagoscopy for, 505.
Förster's operation, 1157.
Foundlings, proper management of, 283, 323.
Fowler, R. S., principles underlying the surgery of the spinal cord and nerve roots, 523.
Fox, H., a simple apparatus for the intravenous injection of salvarsan, 469.
Fracture, and dislocation, practical point in, 585; hyperemia treatment of, 357; of clavicle, 547; of femur in ankylosis of knee, 342; of forearm, treatment of, 449; of metatarsal bones in a child, 486; open treatment, 40; spontaneous, of leg, 1112; treatment of, 163; treatment of, neglected points in, 41.
Frambesia, see yaws.
Francis, R. P., a few remarks on the value of doing nothing, 955.

Freud, method in treatment of psychasthenia, 790; neurosis, doctrine of, 400; see psychoanalysis; theory of and Hamlet, 972.
Freund, M. H., asphyxia of the newborn relieved by placental aeration, 250.
Frink, H. W., dreams and their analysis in reference to psychotherapy, 941.
Funke, J., embolism and thrombosis of the pulmonary artery, 673.
Furniss, H. D., report of four cases of ureteral calculus, 669.
Furunculosis, 785.

G.

Gall bladder, diseases of, catheterization of common duct and enteroclysis for, 228; importance of preserving, 173; revolver ball in, 635.
Gallstones; see cholelithiasis.
Gangosa, 259.
Gangrene, from carbon monoxide poisoning, 1016; in diphtheria, 222; of leg following diphtheria, 808.
Gas bacillus infectious, 692.
Gastroenteritis, 1054.
Gastroenterostomy, late results of, 1112.
Gastrojejunostomy, deaths following, 974.
Generative organs, female, deformities of, 693.
Genius and stature, 1058.
Gerster, A. G., a new variant for ventral hernioplasty, 430.
Glanders, case of, 181; chronic in man, 973.
Glands, ductless, recent investigations on, 304; cervical, enlarged, and carious teeth, 223; cubital, enlarged, in children, 1113.
Glasses, prescription of, 1018.
Gleitsmann, J. W., remarks on the spontaneous disappearance of malignant growths, 719.
Glaucoma, diabetic, 691.
Globulin in cerebrospinal fluid, 828.
Gloves, rubber, and other rubber instruments, preservation and sterilization of, 779; gloves, rubber, who should wear, 488.
Glycosuria, traumatic of newborn, 642.
Goatsbeard poisoning, 623.
Goiter, congenital, case of, 323; exophthalmic, see exophthalmic goiter; intrathoracic, 170; operations, 227.
Goldmann, Dr., the climatic indications of Egypt in otology and laryngology, 436.
Gonococcus causing primary paranephritic abscesses, 869; in the blood in gonorrhea, 962.
Gonorrhea, acute, intravesical irrigation in, 804; general infection with, 549; in childbearing women, 132; in women, 206; in women, treatment, 133; of epididymis, surgical treatment, 314; misuse of prostate in, 827; of conjunctiva, metastatic, 157; recent methods in treatment of, 1068; stock vaccines in, 337.
Gout, diabetes and cystinuria, 835; diagnosis of by purin metabolism, 927; inborn proclivity to, 973; new treatment of, 836; orthodiagnosis and serotherapy of, 680; radium in, 688.
Grafting egg membrane, 489.
Graves' disease; see exophthalmic goiter.
Gray, F. D., direct transfusion, 198.
Greeley, H., a case of pulmonary tuberculosis with heart displaced to right side, 1055.
Griffin, E. A., a case of multiple pregnancy with eclampsia, 342.
Griffith, F., a case of blood extravasation into the sclera from indirect violence, 583.
Gross, M., a contribution to the diagnosis of duodenal ulcer, 720; duodenitis, 62.
Growth, acceleration of, by radium, 787.
Guaiac, tincture of, preparation, 203.
Gulliver, F. D., mental suggestion as a substitute for anesthetics in the removal of tonsils and adenoids from children, 1004.
Gynecology, advances in, 36; posture in, 646; transverse facial incision in, 974; *x*-ray in, 926.

H.

Hald, P. T., a simple method for the relief of certain forms of odynphagia, 333.
Hancock, C. R., appendectomy with cocaine analgesia, 250.
Harvey, William, Weir Mitchell on, 628.
Harvey, T. W., Oliver Wendell Holmes, his work in establishing the contagious nature of childbed fever, 102.
Hayes, W. V. V., street sanitation in New York, 757.
Hay fever, treatment of, 1009.
Hays, H., acute tonsillitis and its treatment, 852.
Health, activities, present day, 703; and washing, 1101; as national assets, 355; public, a department of, 914; public and nurse, 690; public, mutual helpfulness in, 746; public, training for, 1015; resorts, sanitation of, 735; service, public, 871; work, unity in, 158.
Heart, affections of, posture in diagnosis and treatment of, 609, 646; anatomy and physiology, recent advances in, 977; aneurysm of, 3; apex, impure first sound at, 827; arrhythmia of, 88, 266, 744; block, 1052; block and digitalis, 167; calcareous deposit in, *x*-ray shadow of, 450; chronic disease of, hydrotherapy in, 745; deformity of, 736; diastolic sound of, 167; disease, diet in, 504; disease, digitalis in, 507; disease, Nauheim baths in management of, 531; disease of and uterine fibroids, 1110; disease of, cane sugar in, 640; disease, electrocardiograms in diagnosis of, 189; disease of children, lungs in, 702; disease of, prevention, 169; diseases of, treatment, 50; disease of, with unusual symptoms and complications, 651; displaced to right side, 1055; dropsy of, excretion of chlorides in, 268; effect of influenza on, 282; failure, 823, 829; failure of from cocaine, 603; failure, the present day conception of, 818; failure of, reversible pulmonary crepitation in, 974; failure, with pulsus alternans, 1062; functional activity of, 219; in pneumonia, 164; massage of after apparently fatal narcosis, 224; massage of in resuscitation, 1016; transposition of, 962; work of, in aortic insufficiency, 1117.
Heat, tropical, physiological influence of, 732; of sun, relative absorption of by olive-drab and khaki, 210.
Hematocolpos, 1017.
Hematoporphyrinuria in septic infection of uterus, 164.
Hematosalpinx, 597.
Hemiatrophy from scleroderma, 971.
Hemiplegia from head injury, 692; infantile, syphilitic factor in, 926.
Hemoglobinuria, paroxysmal, pathology of, 439.
Hemorrhagic disease of newborn, 690, 1014.
Hemorrhoids, 974.
Heredity and insanity, 1016.
Hernia, diaphragmatic, 77; of intestinal wall, 127; inguinal, operation for, 364; intercostal diaphragmatic, 606, 980; perineal, 549; umbilical with cardiac ectopy, 209.
Hernioplasty, ventral, a new variant for, 430.
Herpes zoster, acute poliomyelitis and zinc phosphide, 958; after injection of salvarsan, 170; and poliomyelitis, 984; and renal colic, 457, 787; bilateral, 921.
Hexamethylenamin, excretion of, in sputum, 1066; in colds, 1156.
Hiccough, treatment of, 880.
Hill, E. C., carriers in relation to the spread of diphtheria, 1043; the high death rate from diphtheria in the United States, the probable causes and means of reduction, with report of cases, 568.
Hip, dislocation of, 450; joint, lesions of and their management, 365.
Hodgkin's disease, simulated by splenic anemia, 981.
Holmes, and Semmelweis, 214; and his work, 349; work on puerperal fever, 102.
Holy man, an Egyptian, 640.
Hookworm disease, see uncinariasis.
Hospital and private practice, 917; and young physicians, 581; as an educator, 536; German, pavilion for thoracic surgery at, 1079; in a civilized community, 926; finances and medical schools, 729; neurological, 408; St. Louis, 1066; organization of staffs of, 1139; organization of University Hospital medical staff, 1142, 1163; teaching, 1066; unit in university work, 317; year, 1066.
Huffman, O. V., the etiology of epidemic poliomyelitis and its possible relation to beriberi, 1095.
Hulner, M., intravesical injection in acute gonorrhea, 804.
Humerus, injuries of lower end of, 598.
Hunter, John, celebration on, 446; and his museum, 413.
Hydatidiform mole with chorioepithelioma, 837.
Hydrocele, 549.
Hydrogen, in the treatment of phthisis, 633.
Hydrophobia; see rabies.
Hydrotherapy, effect of on blood flow in arm, 1117.
Hygiene, college, 881; school, teaching of, 711; social and sexual, 1065; unorthodox, 686.
Hyperacidity, larval, 1025.
Hyperchlorhydria, complications of, 125.
Hyperemia, treatment of fractures, 357; of skin diseases, 357.
Hyperhedonism, 1057.
Hypertrophy, cardiac, study of, 491.
Hypnosis in treatment of psychasthenia, 790.
Hypophysis, effect of components of on blood pressure, 1075; external secretion of, 1057; extract, in obstetrics and gynecology, 79; extract in uterine hemorrhage, 691; extract of, therapeutic use of, 1113; tumor of, 546.
Hysterectomy for diseased adnexa, 222; subtotal, 222.

I.

Ichthyol, in pulmonary diseases, 109.
Icterus, see jaundice.
Idiocy, Mongolian, 163.
Ileum, carcinoma of, 261.

Immunology, 452.
Immunity reaction, 1068; in diagnosis, 594.
Impetigo contagiosa, transmitted by machine oil, 76.
Impotence, senile, question as to, in trial for rape, 1033.
Incision, transverse fascial in gynecology, 974.
Indigestion, 693; intestinal and gastric disturbances, 545.
Industrial diseases, public health in relation to, 257; relation of public health to, 538.
Inebriety, 247; in parent and child, 1101; treatment of, 484; treatment and curability, 152.
Infants, boarding out of, 283; mortality of, 974; feeding of, complemental, 315; feeding of, fats in, 316; sleeping, metabolism in, 1118.
Infantilism, 780; intestinal, of Herter, 1118.
Infections, localized, chemo-immunological studies in, 252.
Influenza, 600; of meninges, 134; pulmonary complications of, 1156.
Infundibulin, see hypophysis extract.
Injections, hypodermic, 1111; painless mercurial, 1111.
Insanity, alcohol and, 964; among brain-workers, 501; and habeas corpus, 411; and heredity, 1016; confusional, 220; crusade for prevention of, 211; in New York State, 157; manic-depressive, 218; modern care of, 690; modern care and treatment of, 512; popular fallacies about, 637; nature, etiology and diagnosis, 3; prevention of, 251, 854; recurrent, 122.
Insurance, state, in Great Britain, 343, 870, 968, 1011, 1061, 1106, 1152.
Intestine, amebæ in, 732; bacteriology of, 785; acute obstruction of, preparatory and postoperative treatment of, 228; antiperistalsis in, 314; chronic stasis of, kinks in 314; chronic stasis of kinks in causation of, 882; chronic stasis of, short-circuiting in, 882; crises of, 867; hemorrhage of, checked by mechanical means, 81; indigestion of and gastric disturbances, 545; malignant growth of, 227; obstruction of, 073, 598; obstruction of, difficulties encountered in late operations for, 697; obstruction of due to kinks, 364; parasites of, 638, 733; putrefactions of and neuralgia, 410; resection of for strangulation by adhesions, 606; tuberculosis of, 747.
Intoxication, postanesthetic acid, 507.
Intubation, in stenosis of the larynx, 1160.
Intussusception, 176, 504; acute in infants, 969; and appendicitis, 925; ileocolic, 605; in adults, 303; in children, 1014; referred penile pain in, 1157.
Iodine, a new solution of for skin sterilization, 675; as antiseptic, 354; as disinfectant, 167; for umbilical cord, 33; in skin sterilization, 640; local sensitiveness to, 321; medication causing thyrotoxic symptoms, 360.
Iodism and thyroidism, 457.
Iodoform, melted ointment of, in suppurating bubo and ischiorectal abscess, 340.
Iritis, etiology, 35, 786, 1018.
Irritation, local, acquired tolerance to, 1150.
Irwell, L., Dr. Woods Hutchinson's prognostications, 29.
Ischias, scoliotica, 268.
Ischiorectal abscess, melted iodoform ointment in, 340.
Isolation, individual, in general wards, 783.

J.

Jacobi, Abraham, proposed for president of the American Medical Association, 963.
Japanese war, death rates in, 618.
Jarvis, N. S., the medical side of the army maneuvers in Texas, 941.
Jaundice after salvarsan, 642; chronic, 548; in acute tuberculosis, 1007; infectious, 1147.
Jaw, tumors of, 229.
Jennings, W. B., criminal abortion, from the practitioner's point of view, 1092.
Johnson, A. B., some remarks on the surgical diseases of the biliary passages, 101.
Johnston, J. C., Stokes-Adams disease, the status of heart block, report of cases, 1052.
Joints, auscultation of, 318, 405; lesions of, and erythemata, 1112; mobilization of, 546.
Judd, A., report of two cases of gastric ulcer due to diseased gall bladder and appendix, 912.

Obstetrics, and animal experimentation, 827; posture in, 646; primitive, 598; scopolamine-morphine anesthesia in, 319.
Odontomes, composite, 219.
Odynphagia, relief of, 333.
Ohlbaum, J., an unusual care of placenta previa, 816.
Olesen, R., vaccination in the Philippine Islands, 390.
Omentum, great perithelioma of, 167.
Operations, complications due to, 176; on nervous women, 122; selection of essentials for, 396.
Opticians, qualification of, 687.
Optic nerve and cranial malformations, 121.
Optics, accurate, 1109
Optometry, at Columbia University, 38, 648.
Orbit, disease of, diagnosis, 264.
Orchitis, primary with secondary parotitis, 547.
Organs, cultivation of, outside of body, 44; extracts and fluids of, mydriatic action of, 359.
Oriental sore, 881; case of, 450.
Osteomyelitis, 980; in measles, 959; non-suppurative, 608; typhoid, 972.
Osteopath, action for libel by, 1166.
Osteopsathyrosis, 966.
Otitis, and mastoiditis in infants, 354; drainage in, 263; media, acute, relief of pains in, 593; media, vaccines in, 1111.
Otology, and laryngology, climatic indications of Egypt in, 436; in Berlin, 267.
Ovary, cyst of, 1067; large cyst of, 226
Oxaluria and diabetes, 155.
Oxygen, insufflation of, in general peritonitis, 630.
Oxypathic diathesis, 156.
Oxyuris appendicitis, 1162.
Oyster beds, inspection of, 547.
Ozena, cured with injections of hard paraffin, 774; specific agent of, 890.
Ozone, 734.

P.

Pacific islands, decreasing population of, 921; medical care of the natives of, 970.
Pain and dysesthesias, 597; relief of by resection of posterior roots of spinal nerves, 378; sense of pleura, 1075.
Palate, cleft, 1112; cleft, operations, 126.
Palmer, F. A., stock vaccines in acute gonorrhea, 337.
Panama, sanitation in, 162.
Pancreas, and diabetes, 543; cysts of, 229, 354; disease of, etiology of, 860; functional diagnosis of diseases of, 1074; sarcoma of, 1157.
Pancreatitis, chronic, 784, 1157; drainage in, 77; gangrenous, 1157; hemorrhagic, 85.
Panhysterocolpectomy, 837.
Pantopon anesthesia, 413.
Paraffin, injections in cure of ozena, 774; injections in facial disfigurements, bad results of, 1162.
Paralysis, agitans, 1065; deltoid, 32; facial and ptomaine poisoning, 36; Landry's, 267; of accommodation, post-diphtheritic, 410; traumatic of brachial plexus, 88.
Parasites, intestinal, 407, 638.
Parathyroids, transplantation of, 567.
Paratyphoid infections, 641.
Paresis, diagnosis and treatment, 35; following syphilis, 784; juvenile, 124; Liquor Belostii test in, 1110; nucleinate of sodium in, 80; relation to tabes, 743; syphilis in etiology of, 306; treated with nucleinic acid injection, 883; tuberculin treatment of, 543; urinary test for, 884.
Parotid gland, angioma of, 642.
Parotiditis and puerperium, 282; and typhoid fever, 262; postoperative, 232; with meningitis, 1128.
Parthenogenesis, mammalian, 924.
Pasteurization, control of, 546.
Patella, fracture of, 265, 876.
Pathology, documents of from antiquity, 725.
Payne, C. N., psychosis from belladonna poisoning, 1154.
Peabody, G. L., medical expert testimony, 1105.
Pellagra, 262, 1156; a disease of digestive tract, 1026; as seen in Italy with reports of cases seen in New York, 421; causation of, 8; recent views on, 586; salvarsan in, 639; treatment of, 66; transfusion in, 230, 453.
Pelvis, contracted, treatment of, 593; contractions of acquired from severe labor, 832.
Pemphigus, chronic, salvarsan in, 545; of mouth and larynx, 870.
Penis, rupture of, 635.
Percussion, and percussion of the kidneys, 201.
Pepsin and diastase in the urine, 827.
Pericardium, effusion of, 882.
Periosteum, bone formation in, 693.
Peritonitis, 689; acute general, 828; adrenalin in, 1113; consecutive to appendicitis, treatment of, 151; insufflation of oxygen in, 630; respiratory movements in, 405.
Peritonization in abdominal surgery, 608.
Pershing, H. T., an unusual case of fracture of the bodies of the fourth, fifth and sixth cervical vertebræ, with injury of the spinal cord, 664.

Pertussis, hydrogen in the treatment of, 633.
Pfahler, G. E., the Roentgen rays as a means of diagnosis of carcinoma of the stomach and bowel, 528.
Phalanx, removal of, 1015.
Phenolsulphonephthalein test, for estimating renal function, 1028; in relation to prostatectomy and nephrectomy, 1028.
Philippines, health conditions in, 313; health problems in, 354; native scouts, beriberi among, 1058; vaccination in, 390.
Phillips, W. C., infant mortality in New York City, 146.
Phosphorus, poisoning, 734; poisoning, and acidosis, 167; white, use of prohibited in Canada, 407.
Photography, stereoscopic, 163.
Phrenology, 409.
Physician and children, 121; and the church, 451; fees of, official tariff for, 1017; gratitude toward, 490; in Germany in 1910, 143; offices, 688; young and hospital, 581.
Picric acid, 638; and burns, 355.
Pick's syndrome, 1014.
Pilcher, J. T., unilateral chyluria caused by the *Filaria sanguinis hominis* treated by, 434, 606.
Pilcher, P. M., unilateral chyluria caused by the *Filaria sanguinis hominis* treated by, 434, 606.
Pittsburg, public health in, 22.
Pituitary gland, see hypophysis.
Placenta, aeration of in asphyxia of newborn, 250; previa, unusual case, 816.
Plague, 925; and its possible spread, 1102; and rats, 371, 404; enzootic, in the United States, 253; eradication of, 546; fleas and rats in transmission, 733; in China, 159; in North China, 547, 1020; Manchurian, significance of for Europe, 508; of Thucydides, 884; prevented by snakes, 589; pulmonary, salvarsan in, 831; rat, 1012; ravages of, 345; ships, disinfection of, 440; swine, intestinal form, 416; Yersin-Roux serum in, 316.
Plaster, adhesive, removal of, 263; jacket, application of, 639.
Pleura, cyst of, 982; pain sense of, 1075; right-sided effusion of, 358.
Pleurisy, with effusion, autoserotherapy in, 650.
Plummer, H. E., possible causes of failure following the use of bacterial vaccines and antisera, 1051.
Pneumocele, of lacrymal sac, 315.
Pneumococcemia, 547.
Pneumococcus, chemoimmunological studies in, 252; vagaries of, 566.
Pneumonia, 961; acute dilatation of the stomach in, 1073; and rheumatism manifestations of tuberculosis, 998; Brudzinski's sign in, 973; camphor in, 145; creosote inhalation in, 315; heart in, 164; lobar, of micrococcus catarrhalis and *Bacillus coli* origin, 180; leucocytes in, 982; lobar prognosis, 899; metastatic from tonsillar abscess, 1159; quinine and urea hydrochloride in, 1072; serum treatment of, 712; topography of localization in children, 360; treatment of, 36, 506.
Pneumothorax, 1112; diagnosis of, 268; of long standing, 982; traumatic, 1068; with acute abdominal symptoms, 506.
Poisoning, carbon monoxide, 1017, 1111; belladonna, acute psychosis due to, 1050; benzol, acute, 1158; eucalyptus oil, 455; Goatsbeard, 693; lead, 357, 881, 1017; phosphorus, 731; potassium permanganate, 50; tin, 832.
Poisons and drugs, action of, 599.
Polk, W. M., inaugural address of the President of the New York Academy of Medicine, 237.
Poliomyeloencephalitis, 162.
Poliomyelitis, 66, 299, 698, 735, 1064; abortive, 506; and herpes zoster, 958, 984; and house flies, 1156; artificial muscles in the early stages of, 435; assistance from school physicians in, 695; early, etiology of and possible relation to beriberi, 1095; exercise machine for, 881; experimental, 411, 453; in Bristol, 640; in Canada, 781; microorganism in the blood of acute cases of, 441; nasal secretion in, 829; pains of, 220; prevention of, 1104; recent experience, 35; treatment of, 162; unusual case of, 691.
Politics, in the profession, 72; versus science, 67.
Polygraphic machine, automatic, 1155.
Polycythemia, 651.
Population, density of, 23; of Pacific islands decreasing, 921; prevention of lessening of, 448.
Posture, in combined abdominal and pelvic operation, 226; in diagnosis and treatment of cardiac affections and dropsical effusions, 699; in diseases of the heart, 646; in gynecology, 647; in obstetrics, 646; operative, 505; orthograde, 35.
Potassium permanganate as a hemostatic, 881; poisoning, 550.
Potatoes in diabetes, 877.
Powers, C. A., an unusual case of fracture of the bodies of the fourth, fifth, and sixth cervical vertebræ, with injury of the spinal cord, 664.
Pregnancy, abdominal, 972; and diseases of eye, 1110; and tuberculosis, 36; anaphylaxis of, 831; as a relief for visceral ptosis, 1155; breast abscess during, 354; diabetes of, 927; extrauterine, 971; extrauterine repeated, 599; in tuberculous women, hysterectomy in, 630; interstitial, 166; intraligamentous, late, 829; multiple, with eclampsia, 342; ovarian, 450; pyelitis of, 124, 221, 927; serum diagnosis of, 1006; toxicoses of, 127; tubal, 886, 1110; vomiting of and adrenalin therapy, 627; *x*-ray diagnosis of early, 642.
Prescriptions, not private documents, 795.
Pressor bases, of urine, 1112.
Pressure, blood, see blood.
Prize, Marie Feodorovna, 727.
Procidentia, complete abdominal exclusion of fundus in, 365.
Proctoclysis, 285; apparatus for, 165, 639.
Prostate, hypertrophy of, 636; hypertrophied, care of, 698; hypertrophy of high frequency current in, 606; hypertrophy of, treated by *x*-ray and high frequency current, 605; misuse of in gonorrhea, 827; removal of, time and method, 260; total enucleation, 786; utricle of, 546.
Prostatectomy, 783.
Prostitution and venereal diseases, 691; and venereal diseases in New York City, 637; regulation of, 76.
Proteins and proteolytic ferments, chemistry of, in relation to surgery, 794.
Pruritus vulvæ, psychogenic, 975.
Pylorospasm, 229.
Pseudoleucemia, treated by salvarsan, 493.
Psychasthenia, treated by hypnosis and Freud's method, 790.
Psychoanalysis, 734.
Psychopath, youthful, 409.
Psychoses, acute, due to belladonna poisoning, 1050, 1154; alcoholic, pupils in, 972; of child-bearing, 623; puerperal, diagnosis of, 267; traumatic, 697, 1018.
Psychotherapy, uses and abuses, 30; future of, 58.
Pubiotomy; vesical calculus following, 1119
Public Health and Marine Hospital Service, annual report of Surgeon General of, 399.
Puerperium, and parotiditis, 282; autoinfection of, 457; eclampsia of, see eclampsia; fever of, contagious nature established by O. W. Holmes, 102; infections of, 939; psychoses of, 267; sepsis of, after spontaneous birth, 1069; sepsis of, vaccines in, 783; streptococci in, 93; thrombosis and embolism, prodromes, 224.
Pulmonary artery, embolism and thrombosis of, 673.
Pulmonary stenosis, congenital, 265.
Pulmonary tuberculosis, 1110; case of, with heart displaced to right side, 1055; chlorides, phosphates, and sulphates of the urine in the last stage of, 867; early diagnosis of, 1111; gastric ulcer and, 507; inhalation treatment, 167; leucocytes in, 982; rôle of tuberculin in, 697; specific diagnosis of, 33; treatment of, 266; treatment of, at high altitudes in the tropics, 544; typical and atypical, 169; ultrachronic, 166.
Pupils, in alcoholic psychoses, 972.
Purgatives, 396.
Purpura, 659.
Pus, ill-smelling, not necessarily objectionable, 397.
Pyelitis, in infancy, 505; of pregnancy, 221, 524; of pregnancy, treatment of, 926; of pregnancy, cystoscopy in, 695.
Pyemia following spermatocystitis, 1019.
Pylorospasm, 97, 229.
Pylorus, congenital stenosis of, 354; partial obstruction of, 973; stretching of, in benign stenosis, 1022; stretching of, in benign stenosis, 1035; spasm of, 97, 229; stenosis of, latent, 817.
Pyocyanase for diphtheria carriers, 695.
Pyopneumothorax, healed, from swallowing dental plate, 641.

Q.

Quackery, cancer, and credulity, 1113; and women, 1113; in rural districts, 1113; in East Anglia, 1113; in skin diseases and cosmetics, 1113.
Question, hypothetical, 795.
Quinine and urea hydrochloride, 923; as a local anesthetic, 697; in pneumonia, 1072.

R.

Rabies, 689, 734, 880; histological diagnosis of, 208; peculiar complication of Pasteur treatment of, 415; microorganisms of, 827.
Race, degeneration and eugenics, 1007.
Radiography, see *x*-rays.
Radium, accelerating growth, 787; in cancer, 507, 878, 1067, 1107; in gout and rheumatism, 358, 688; therapy, 75, 917; water therapy, 926.
Rats, and plague, 311, 404; plague, 1012.
Reciprocity, interstate, 511.

Rectum, and sigmoid colon, direct inspection of, 243; cancer of, operative treatment, 974; cancer of, 350; fibrous stricture of, 690; surgery of, syringe for local anesthesia in, 315.
Reflexes, and eyestrain, 313; aural, 313; dependent upon eyestrain, 367; dependent on nose and throat conditions, 368; in diseases of nervous system, 314, 369; in surgical diagnosis, 313, 367; meaning of, 314, 368; nasopharyngeal, 313; paradoxic, 597; referable to ear, 368.
Registration, medical, law held constitutional, 607; sufficiency of, 513; voluntary and intentional, 1026.
Reilly, T. F., the prognosis of lobar pneumonia, 899.
Respiration, irregularities of in meningitis, 1072.
Rest, the value of doing nothing, 955.
Resuscitation, by cardiac massage, 1016; electric, 411.
Rheumatism and chorea, 824; and gout, radium in, 688; and pneumonia, manifestations of tuberculosis, 998; gonorrheal, vaccines in, 638; hypodermic injections of salicylates in, 432; nature of, 577; rarer occurrences of in childhood, 168; salicylates in, 1062; vaccines in, 264.
Rhinopharyngitis mutilans, 259.
Rhinoscleroma, 596.
Rice, and beriberi, 689; as a food, 690; polished, restriction of use of, 503.
Rickets, as cause of spinal curvature, 415.
Ring bodies, significance of, 827.
Ringworm, of scalp, education and segregation of children affected with, 910, 930; *x*-ray treatment of, 454, 1156.
Roberts, D., the causation of belching, 1002.
Robinson, W. J., acute arthritis of chemical origin, with report of three cases, 625; sterility in woman and in man, 404.
Rollier, method of, in treatment of bone and gland tuberculosis, 86.
Rongy, A. J., primary sterility in women.
Rosanoff, A. J., the prevention of insanity; hygiene of the mind, 854.
Rouglin, L. C., reactions to tuberculin, 722.
Royster, H. A., melted iodoform ointment in the treatment of suppurating bubo and ischiorectal abscess, 340.

S.

Salicylates, hypodermic injection in rheumatism, 434; in rheumatism, 1062.
Salicylic acid and hexamethyenamin excretion of in sputum, 1066.
Salvarsan, 45, 46, 72, 81, 84, 118, 165, 170, 220, 314, 327, 412, 452, 456, 505, 545, 547, 553, 596, 597, 640, 641, 697, 730, 732, 742, 743, 806, 814, 876, 880, 923, 1075, 1112; administration of, 412; and arsenic cancer, 925, 970; and auditory labyrinth, 545; and cranial neuritis, 1015; and ear, 883; and mouth spirochetes, 81; and nerve disturbances, 80; and optic neuritis, 543; and regeneration of bone, 81; and syphilis maligna, 169; and Wassermann reaction, 75, 554, 1109; apparatus for, 545; apparatus for intravenous injection, 469, 829, 889; collateral effects of, 457, 743; death from, in subjects with cardiovascular disease, 1069; edema after, 316; emulsion of, 545; ethics of, 120; followed by nephritis, 832; herpes zoster after injection, 170; icterus after, 642; in Banti's disease, 695; in children, 355; in chorea minor, 268; in chronic pemphigus, 545; in yaws, 456, 507, 641, 876; in inherited syphilis, 312, 1012; in malaria, 268; in malignant tumors, 927; in pellagra, 630; in pemphigus neonatorum, 359; in pernicious anemia, 599; in pseudoleucemia, 493; in pulmonary plague, 831; in syphilis of nervous system, 288; in ulcerous stomatitis, 549; in unilateral chyluria caused by *Filaria sanguinis hominis*, 434; injection of, into lumbar muscles, 515; intravenous injection of, 504, 554; intravenous administration, simplified technique, 983; local action of, 127; neurotropy of, 641; oily suspensions of, 504; pain and abscess following, 881; precautions in, 317; serum, 787; technique for preparing, 410, 743.
Sanitation, in Australia, 1013; modern, 493; of army camps, 539; of health resorts, 735; Pennsylvania's work in rural, 1146; street in New York, 757.
Sanatoria, dietaries in, 261.
Sarcoma, Coley's method in, 200; cells, migration of, 597; cultivation of, 123; cultivation *in vitro* of, 453; of appendix, 121; of pancreas, 1157; of submaxillary, 354; originating on surface of lupus carcinoma, 834.
Satterthwaite, F. E., electrocardiograms and their significance, 80.
Scalp, chancre of, 1018.
Scapula, crepitus over, 787.
Scarlet fever, and desquamation, 695; analysis and statistics of, 309; etiology, 927; Rumpell-Leede, phenomenon in, 831; Wassermann reaction in, 470.
School, children, hospital treatment of, 687; children, left-handedness in, 537; children, medical treatment of, 215; children, medical inspection of, 866, 1155; children, treatment of, 380; fresh-air, 120; inspection in small towns, 922; medical inspection of, 690; medical, weak, 453; nurse, 784.
Sclera, blood extravasation into, 583.
Scleroderma, hemiatrophy from, 971.
Sclerosis multiple, 599; treatment of, 222.
Scoliosis, 826.
Scopolamine, morphine in labor, 830.
Scorbutus infantile, 598.

Thread, impregnation test, for ulcers of upper digestive tract, 475; linen, best, 397.
Throat, colon bacillus infection of, 879.
Thromboangitis obliterans, 87.
Thrombosis and embolism, puerperal, prodromes, 224; of femoral veins after severe colitis, 1159; of superior vena cava, 1067; venous, 167; venous, pulmonary symptoms as premonitory signs of, 753; venous, pulmonary symptoms of, 791.
Thymus, enlargement of, with myasthenia, 266; enlarged, percussion sounds of, 1117; functions of, 438; pathology of, 550; physiological and clinical significance of, 398.
Thyroid, acute inflammation of, 786; enlargement in school children, 736; extract in carcinoma, 507; function of, 505; lingual, 983; toxic symptoms of, following iodine medication, 360.
Thyroidectomy, collapse of trachea during, 228.

Thyroidism and iodism, 458.
Tin poisoning, 832.
Tissue, cultivation of, 123.
Toad, tropical, poisons of, 1066.
Tobacco dyspnea, 1157; psychosis, in a boy, 415.
Tobie, W. E., surgical anatomy of the abdominal wall with reference to appendectomy, 13.
Toe, reflex, extensor, 924.
Tongue, hairy, 33.
Tonsils, and adenoids, removal of, with aid of mental suggestion, 1004; and Graves' disease, 31; enucleation of, 783; knife for, a new, 314, 317; palatine, functions of, 738; removal of, 636; seizing forceps, 826; soap and cholesterin in, 450.
Tonsillectomy, 638; hiccoughs after, 261; simple complete, 221.
Tonsillitis, acute, 507; acute, and its treatment, 852; causing chronic urethritis and ureteritis, 173.
Townsend, T. M., functional sexual disorders proceeding from the genitourinary tract, 950.
Toxemia, acute intestinal, in infants, 209.
Trachea, foreign body in and lymphatism, 260; collapse of, during thyroidectomy, 228.
Trachoma, 504, 690; etiology, 302; carbolic acid in, 1154; in Cuba, distribution of, 1098; theory of, 121.
Transfusion, direct, 198; disease, 1158; in pellagra, 230, 453; of blood in pernicious anemia, 239.
Trichinosis, 735; serum diagnosis of, 737.
Trichobezoar, in the stomach, 508.
Tricuspid stenosis, 1118.
Trimble, W. B., a simple apparatus for the intravenous injection of salvarsan, 469; impressions as to the value of salvarsan, 814.
Tropics, affections of, progress in knowledge of, 305; alcohol in, 343, shortening of life in, 586.
Trypanosoma lewisi, transmission of, 975, 1158.
Trypanosomiasis, 119, 310, 350, 505; chemotherapy of, 614, 648; gambiense, 1076.
Tuberculin, diagnostic value of, 532; dispensaries, 415; formed in body, fate of, 416; inoculation of, with local anesthetic, 413; local reactions of, 220; reactions to, 722; reaction, mechanism, 550; skin reaction in syphilis and metasypbilis, 817; test present status of, 1071; treatment of paresis, 543.
Tuberculosis, acute leucemic, 1119; among Philippine scouts, 30; and alcoholism, 441; and intraocular hemorrhage, 550; and milk, 924; and pregnancy, 36; and syphilis, 877; apex findings in, 321; as a diathetic disease, 1100; bacillus of, see bacillus; bone, joint and gland, treated by direct exposure to the sun, 86; bronchitis in, 784; campaign against, 161; campaign in Berlin, 731; climatic treatment of, 879; clinics in Berlin, 731; control of bovine, 73; cough during auscultation in, 262; dispensary treatment of, 30; dietaries in sanatoria for, 261; genital cured by *x*-rays, 884; hydrotherapy in night-sweats of, 1128; ichthyol in, 100; immunity reaction in, 506; in Pennsylvania, 316; in poor, medical provision for, 592; infantile, miostagmine reaction in, 642, 950; in pregnant women, hysterectomy in, 630; infections in childhood, 508; infection in human and bovine, 113; intestinal, 747; jaundice in acute, 1007; laryngeal, rational treatment of, 1084; local, from bovine bacilllus, 416; malaria, simulating, 1111; meningeal, of new-born, 1008; meningeal, tubercle bacilli in, 133; mercury in, 596; of cecum and colon, 692; of ankle, 1155; of hip joint, 268; of joints treated by ileocolostomy, 925; orthostatic albuminuria in, 1019; renal; renal, diagnosis of advanced, 922; renal, early diagnosis of, 175; renal, in women, 1110; renovesical, 451; rest and movement in, 79; rest, exercise, and food in, 76; sanatorium, selection of patients for, 460; sending away of case of, 1111; serum diagnosis of, 124; statistics of, 493; treatment of, 698; urinary, 28; vaccine treatment of, 657; tuberculin in, see tuberculin; war against, 310; zomotherapy in, 167.
Tube, drainage, new, 975.
Tubing, rubber, 488.
Tumors, desmoid, 271; formation of, and acari, 507; formation of, and diabetes, 210; growth, inhibition of, 736; intraspinal, cerebrospinal fluid in, 78; mesothelial, 1075; of breast, 597; implantation of, 547; transmission of, 221; transmissibility by means of cell-free filtrate, 774.
Turbinates, syphilis of, 829.
Tsetse flies, control of, 27.
Tympanum, absence of floor of, 504.
Typhoid bacillus, in the feces, 1148; phagocytosis of, 86.
Typhoid fever, absorption of fat in, on high caloric dfet, 181; and dysentery, deficiency of calcium salts in, 492; and parotiditis, 262; and water storage, 493; cholecystitis, 364; diet in, 314; epidemic, 785; house epidemic of, 829; infectivity of, 598; infection of, 267; inoculation against, 120; investigation of an outbreak in a typhoid camp, 517; Manchurian and Brill's disease, 535, 623; vaccine, 785; vaccination against, 635, 734; vaccine treatment, 707, 1120, 1161.
Typhus fever, microorganism of, 916.

U

Ulcer, duodenal, see duodenum; gastric, see stomach; of upper digestive track, thread impregnation best for, 475; manual treatment of, 1014; rodent, of the thigh, 548; rodent, treatment of, 169, 598.
Umbilical cord, iodine for, 33
Uncinariasis, 735; in mines, 203; in Philippines, 733; prophylaxis by means of efficient sboes, 534.
Unfit, problem of the, 399.
University work, hospital unit in, 317.
Ureter, anastomosis with uterus, 264; calculus of, 635, 1120.
Urethra, concealed chancre of, 147; instrumentation of, 262.
Urethritis and ureteritis caused by tonsillitis, 173; gonorrheal, and cystitis in women, 206; of chemical origin, 625.
Uremia, renal decapsulation for, 738.
Ureter, calculus of, 669.
Urine, chyle in, see chyluria; collection from female infants, 504; diastatic enzymes in, 1069; enzymes in the, 820; in last stage of pulmonary tuberculosis, 867; incontinence of, in women, 1089, 1120; new Diazo reaction in, 352; of Marathon runners, 540; pepsin and diastase in, 827; postoperative incontinence of, 868; pressor bases of, 1112; retention of, 548; separation of in bladder, 447.
Uterus and adnexa, control of pain of, 638; and ovary, active substances of, 207; cancer of, 229; cancer of, and its early diagnosis, 897; cancer of, inoperable, acetone in, 1110; cancer of, value of uterine sound in, 890; carcinoma of, danger of mistakes in diagnosis of frozen unstained section, 886; cervix of cancer of, ultraradical operation for, 457; chronic obstetrical inversion of, 188; dislocated puerperal, 31; fibroids of and cardiac disorder, 924, 1110; fibroids of, growth of after menopause, 837; fibroids of treated by *x*-rays, 155; fibroids of mistaken for malignant tumor, 886; hemorrhage from, infundibulin in, 691; hemorrhage from, local hematological factor in, 740; hemorrhage from, utriculoplasty in, 1016; inverted, prolapse of, 320; perforating wounds of, 809; perforation of, 219; prolapse of, 830; reaction of mucosa of, from artificial placentation, 884; removal of for diseased adnexa, 222; retrodisplacement of, operation for, 741; retrodisplacement of, plication of anterior broad ligament for, 365; septic infection of, hematoporphyrinuria in, 164
Utriculoplasty, for uterine hemorrhage, 1016.

V

Vaccination, and revaccination, 79; and smallpox in Latin America, 345; in army, 744; in Japan, 639; in the Philippine Islands, 390; multiple, 506; modern in United States, 679; opposition to in Berlin, 731; protective, 642; tetanus after, 354.
Vaccines, and antisera, failure following use of, 1051; and pulmonary hemorrhage, 33; in acute mastitis, 836; in mastoiditis and sinus thrombosis, 979; in otitis media, 785, 1111; in puerperal sepsis, 783; in rheumatoid arthritis, 1017; in rhinitis, 267; in peritonitis following operation for perforated gastric ulcer, 338; in rheumatoid arthritis, 320; in sepsis, 61, 978; in typhoid fever, 500, 734, 797; old staphylococcus, therapeutics, 76; one thousand inoculations of, 266; polyvalent, clinical experience in, 746; shaker, 562; stock, in acute gonorrhea, 337; therapy of and general practitioners, 1062; therapy of, present status of, 985; typhoid, 785.
Vacuum pump in sinus disease, 597.
